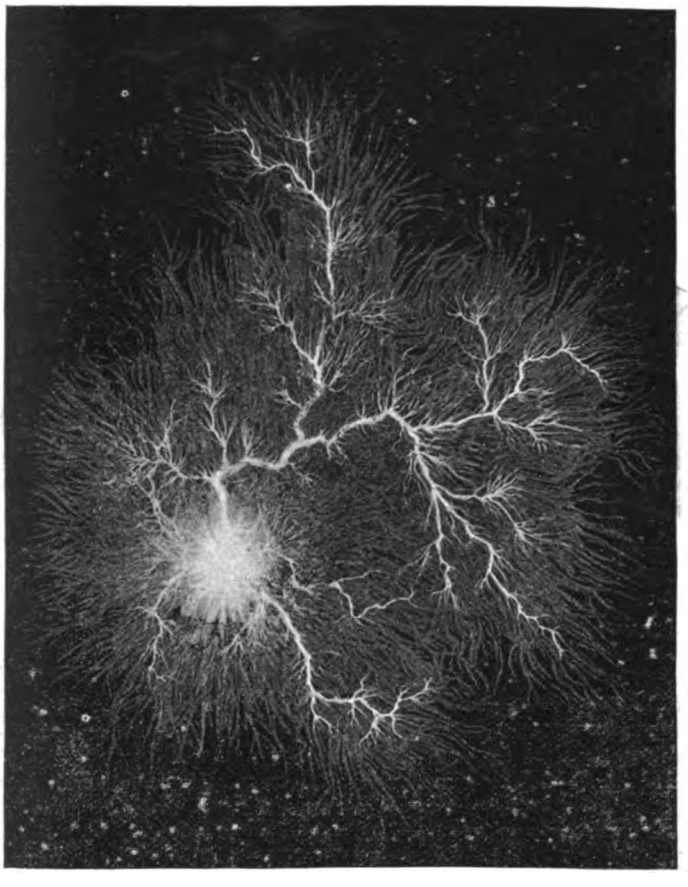
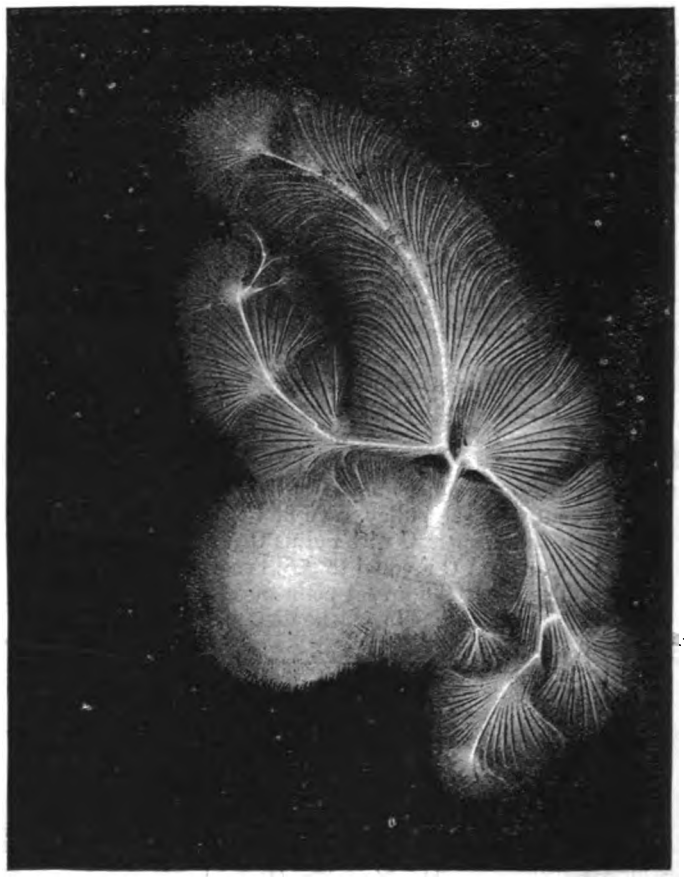
The photographs that we reproduce in the present issue were taken by Mr. A. A. Campbell Swinton without either camera or lens, by merely causing the electric discharge from an induction coil to take place across the sensitive surface of an ordinary photographic dry plate in a perfectly dark room. These photographs were shown by Mr. Swinton at the recent meeting of the British Association in Edinburgh. As was well illustrated in the case of the beautiful experiments at the Crystal Palace, when a plate of glass is placed between the discharging points of a coil or transformer producing a sufficiently high potential, the discharge spreads out over the surface of the glass. With a plain piece of glass there is, of course, a discharge on both sides of it ; but if one side is covered with tinfoil, the discharge will only spread out on the opposite side. If, for the plain glass plate, we substitute a sensitive photographic plate, the back of which has been covered with foil, we have a similar effect. The discharge spreads out on the surface of the sensitive film, and having made a single positive or negative discharge in this way, we have only to develop the plate, in order to produce figures like those illustrated. It may be mentioned that the gelatine and bromide of silver coating that constitutes the sensitive film, does not seem to have any particular effect in modifying the form or character of the discharge ; and the photographs, therefore, are accurate representations of the actual discharges that take place over any insulating surface.



Photograph of a Positive Electrical Discharge



Photograph of a Negative Discharge.

The entirely distinct characters of figure produced by positive and negative discharges respectively will be observed, and it is worthy of note that though the figures invariably differ in form, the general characteristics for positive or for negative, as the case may be, are always the same. It is not easy to suggest any reasonable theory to explain this remarkable difference in the effect of positive and negative discharges. It can, no doubt, be pointed out that, while the negative discharge with its regularly curved lines of flow points to something of the nature of momentum, there is no such evidence in the case of the positive discharge. This, however, does not amount to much, and in the present state of electrical knowledge we must be content to class the phenomenon among the other unexplained differences that are known to exist between what we are pleased to call positive and negative electricity.

Another point to be noticed is the remarkable similarity between the figures and some organic forms, such as some kinds of seaweed in the case of the positive, and feathers or

Digitized by Google

branches of palm leaves in the case of the negative. The photographs, in fact, present another curious instance of the remarkable manner in which, under favourable conditions, dead inorganic matter will assume the structural forms that are generally associated with organic life.

THE BRESCIA TELEPHONE EXCHANGE.

It is an unfortunate, but at the same time an indisputable fact that telephone exchanges which have a great number of subscribers, and especially if they are in large towns, work less satisfactorily than smaller exchanges. The universality of this fact shows that such defects cannot simply be attributed to the negligence of the directors, or of the telephone engineers. On examination of the sounds heard in a town telephone, we hear voices in conversation; the clatter of the Morse, which in some instances becomes almost a roar, and a crackling noise, which is caused partly by atmospheric electricity and partly by earth currents. All these disturbances are caused either by induction or leakage from neighbouring wires and earth. It

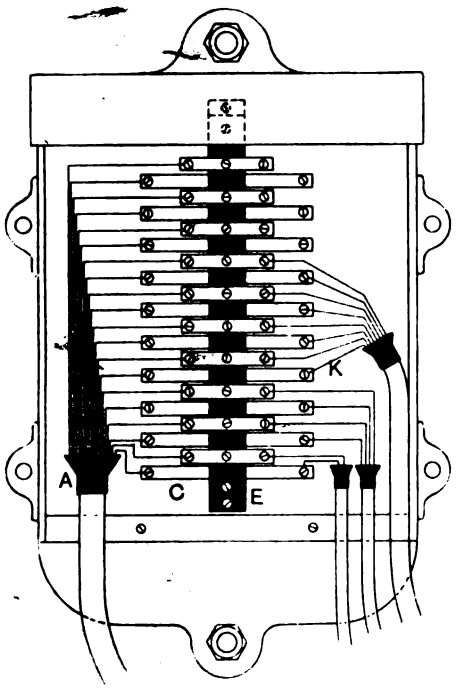


Fig. 1.—Brescia Telephone Exchange. Junction Box for Block of Houses.

is generally supposed that a little care in the insulators, &c., will result in the practical abolition of these troubles; but experience shows that even ebonite has not under certain circumstances sufficient insulating power to prevent telephonic currents leaking from one wire to another when these are fixed upon the same ebonite plate. Another point worth noting is that in telegraphic instruments, where, so to speak, the current works upon dead instruments made of brass and iron, the effects are proportional to the acting forces; but in the telephone, metallic instruments work upon the human ear. Now Prof. Fechner, of Leipzig, and after him Prof. von Helmholtz, have shown that if the intensity of light or sound changes in arithmetical progression, the effect produced on the eye or ear varies logarithmetically. This law, known as the Fechner-Helmholtz psycho physical law, is of the highest importance to the telephone engineer because it shows in what an enormous proportion we must augment the intensity of the vibration in a telephone if we want to double the effect, and, on the other hand, in what enormous proportion we can diminish such intensity without perceptibly diminishing the effect. Now these facts would appear to point to the absolute necessity, not merely of good, but of perfect insulation, in other words to underground conductors, and to the futility of increasing battery and instrumental power.

A few particulars with regard to a small but well thought-out exchange erected on these lines by Dr. A. von Wurstemberger in 1885 at Brescia, an Italian town of some 40,000 inhabitants, may therefore be of some interest. Here Hunning's transmitters of the Hipp pattern *without* induction coils and ordinary Bell receivers have been installed. With regard to the network the general idea consists in laying down the cables (Berthoud-Borel) underground, and in bringing the ends up the walls of the houses to the height of the first floor. Each cable contains from 4 to 20 wires, and terminates in a box, shown in Fig. 1. A is the cable coming from underground, the wires being fixed to terminals C, which are fastened on the ebonite piece E. From the other side of the box we see the cables which go alongside the front of the houses, or block of houses, to the subscribers, so that from the subscribers to the central office the whole line is represented by a double wire highly insulated and covered with lead. Only those subscribers who are at a certain distance out of town are served by an overhead wire on poles starting from the boxes; but as the number of these subscribers is relatively small, and between the boxes and the central exchange the connection is made by cable, induction and leakage are even on those lines of very little importance. The object of the boxes distributed all over the town is to render the underground cable network easy to tap without opening streets or cutting a cable.

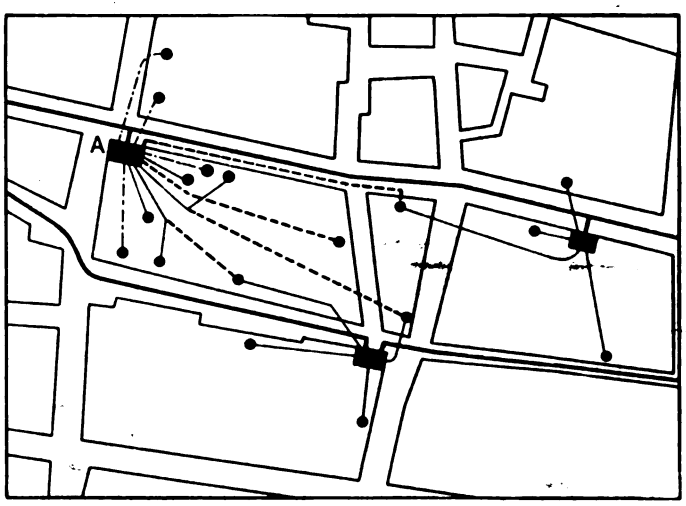

Fig. 2.—Brescia Telephone Exchange. Section of Underground Network.

Wall Box. ——— Main Cable.
● Telephones. – – – – Service Wires.
------- Service Wires disconnected from Box A.
——— Service Wires, run in place of others disconnected.

From Fig. 2 we can see how alterations in the connections can be made without disturbing the streets. Box A was one put up at the beginning; at that time there were only four subscribers to be served who were partly in the same block and partly in the neighbouring blocks. After a short time the twelve remaining wires were taken by new subscribers, and as there was a certain number more to be served new cables had to be laid down. This was not done as might be expected along the old mains, but another line of streets was followed, and boxes were put up on other blocks. Now those subscribers that were some little distance from the first box were connected with the new box, giving thus free lines in the first box to be used as required. The cables taken off the front of the houses were utilised again, and no material was lost.

The laying down of the main at the beginning was managed in such a way that no disturbances in the traffic of the town took place. A little ditch about a foot deep was opened in the day time running alongside the pavement, this little ditch was discontinued at all main crossings of streets. In the evening, generally after 10 p.m., gangs of workmen opened the ditch at the crossings, and by one o'clock at night cable cars began running out the cable into the ditch. As soon as a sufficient number of cables was laid some coal tar and sand were poured over them, and then came tiles, earth and pavement flags fol-

Digitized by Google

lowed. The laying down of the cables was carried out between one and six o'clock in the morning, the closing of the main street crossings between 6 and 7:30 a.m., and the filling up the ditches and replacing the pavement was generally terminated at nightfall. In about three to four nights the whole of the cables had been laid down in this way.

As to financial results, the Company has always paid a good dividend (between 4½ and 5 per cent.), and part of the extensions have been paid for out of profits. The cables themselves, as well as the whole plant, showed little deterioration or change in the insulating power, and repairs have only been necessary in a very few instances, where gas or water supply men have dug up a cable by accident and damaged it.

PROPOSED PACIFIC CABLE.

Mr. Sandford Fleming has addressed a letter to Sir John Lubbock, Bart., M.P., the President of the Second Congress of Chambers of Commerce of the Empire, of which we give a summary below. It will be seen that Mr. Fleming advocates the laying of a submarine cable from Canada to the Australasian Colonies under subsidies from the Imperial and Colonial Governments interested. The matter was discussed in *The Electrician* of May 6th, and it was there shown that the subsidies would have to be very large or the working of the cable would be conducted at a loss.

There is a further point which Mr. Fleming does not touch upon. So long as the Australian Government guarantees a portion of the loss due to the low rates on the telegraphic traffic with those colonies, it is not probable that they will very largely add to that loss by fostering a competitive line in addition to paying a subsidy in respect of the proposed Pacific Cable. In addition to this India is interested in the Australian rate, and the Imperial Government may not be inclined to give a subsidy for a cable which will take away a certain amount of revenue from the Indian telegraphs. That a Pacific line would have a certain value for commercial and strategical reasons no one doubts; but a long single stretch of cable such as that could afford no great advantage in time of war. The depth of water which Mr. Fleming thinks would afford it security certainly would not prevent it being cut, and as certainly would add difficulty and delay in repairing it.

The greatest safeguard for submarine telegraphic communication in time of war is to have as many routes as possible, in the hope that they will not all be interrupted, and to have them in such short sections that despatch boats can quickly bridge over the interrupted sections when necessary. Further, if any attempt is to be made to protect cables, it can only be done where they lie along the track of commerce, which would be patrolled by our cruisers. If the navy were to do nothing else it could not prevent a Pacific cable being cut.

Strong exception must be taken to the statement that the soundings prove the existence of a sea floor in the Pacific probably not less favourable for cable laying than that of the Atlantic. It is only necessary to compare the soundings on the two charts to see that this is not the case.

Then, again, Mr. F. N. Gisborne is referred to "as the man who projected and took no small part in establishing the first Atlantic cable," and Canadian newspapers make the same claim. After exercising considerable care to ascertain the facts as to the inception of the idea of a cable across the Atlantic, the truth appears to be that Mr. Gisborne endeavoured to interest the late Mr. Cyrus Field in an attempt to connect Newfoundland and the United States by cable. Mr. Field was not disposed to take up a matter of that kind; but after the interview with Mr. Gisborne, looking at a globe, he asked himself the question, "Why not continue the line to Europe?" This was an idea which fired his enthusiasm, and he at once wrote to Prof. Morse and Lieut. Maury. The latter replied first, stating that when he received Mr. Field's letter he was just closing a report (dated February 22, 1854) to the Secretary of the United States Navy, showing that soundings proved the bed of the Atlantic to be very suitable for a cable to lie on, and referring to what he christened the "cable plateau." Prof. Morse told Mr. Field that as early as August 10, 1843—11 years before Mr. Gisborne met Mr. Field—he had written to the Secretary of the United States Treasury, giving the results of certain experiments made in the harbour of New York, to show the power of communicating electrically at great distances, at the close of which he said: "The practical inference from this law is that a telegraphic communication on the electro-magnetic plan may with certainty be established across the Atlantic Ocean. Startling as this may now seem, I am confident the time will come when this project will be realised."

Now, if honour is to be given where it is due, it seems to us, and we certainly have no prejudice in the matter, that it is to America, and not to Canada, that the inception of ocean telegraphy is due. Mr. Gisborne is certainly entitled to the credit of interesting Mr. Field in submarine telegraphy, and the latter to that of being the chief instrument in attempting the laying of the first and second cables, although the first was unsuccessful and the second only worked four months.

It may also be pointed out that the shortest available route to Australia is from California to New Zealand, and although we should naturally prefer to see the line when laid terminate at Vancouver or Victoria (Canada), it certainly appears probable that the first section of a Pacific cable will be laid from San Francisco to Honolulu, under subsidy from the American Government. Should this be so it will considerably weaken the claim of Canada to be the starting point.

The question of laying a cable across the Pacific has been agitated for 25 years, more than one company having been formed for the purpose; and apparently while leading Canadians are writing papers, making speeches, and getting resolutions passed at Commercial Congresses, America will play the first card.

Mr. Fleming wrote that he did not propose to dwell on the importance and even the necessity of a complete telegraph system as a means of defending our world-wide Empire, quite apart from its commerce. This almost self-evident proposition had been set forth at other times and places. He would consider the subject mainly from its commercial aspects. A large part of the discussions at the Congress had turned upon drawing more closely the links of connection not only between the Mother Country and the outlying parts of the Empire, but also between the various great groups of colonies. The strongest views had been uttered upon this point, and resolutions had been formally presented and unanimously passed, giving expression to the opinion that every step should be taken which would tend to increase the feeling among British subjects in every part of the world that they were one people and that they had common interests in trade and commerce. That the telegraph had already operated towards this end in a very remarkable way was evident to all, that it may do so still more in the future was equally clear. Few questions, therefore, could have higher claims upon the attention of the Chambers of Commerce of the British Empire than those which related to telegraphic communications. The application of electricity to telegraphy had given to the world an entirely new means of communication at once the most sensitive and the most useful that the mind of man could conceive. In no department of human activity was its utility more constantly thrust upon us than in the fields of commerce. Everywhere the opening of trade relations was quickly followed by the construction of telegraph lines; indeed, in new countries, such as Canada and Australia, the telegraph was not seldom the pioneer of settlement and railways. Everywhere the connection by telegraph and cable stimulated and facilitated commercial intercourse. The extraordinary extent of the change thus brought about was illustrated by the fact, that for communication across the Atlantic no less than ten submarine cables were now in constant use instead of the one which first came into continuous use a quarter of a century ago; it was further strikingly illustrated by the rapid growth of telegraphic intercourse with the East and Australasia, necessitating an increase in the number of wires employed. Already more than £1,000 per day were spent on telegraphic communication between the United Kingdom and the Australasian Colonies alone. British shipping, which controlled so large a part of the carrying trade of the world, had come to depend in great measure upon telegraphic advice for its most effective employment. The overwhelming relative interest which British people had in this comparatively modern means of communication was further proved by the fact that out of 125,000 miles of ocean cable now in existence, at least 90,000 were owned by our people and carried on under their management, leaving only about 35,000 miles, or about one-fourth of the whole, for all the other nations of the world. The proportion furnished no bad measure of the preponderance of British commerce. Great, however, as British enterprise had been in the matter of cable construction, the development of the outlying parts of the Empire was constantly making upon it new demands. One great field had been left entirely untouched.

It may almost be taken for granted that as British commerce expanded nothing short of a complete system, bridging all the great oceans, would fully satisfy its wants. For the present the Atlantic was not inadequately provided for by ten cables, while another was now being added to the two laid to South America. The configuration of the Indian Ocean made the various lines which skirted its coasts satisfy the immediate necessities of

Digitized by Google

the case. The Pacific alone was not traversed by a single line of wire. That this condition of things presented a serious hindrance to commercial development; that from a strategic point of view it indicated a serious flaw in our national system for the defence of commerce, were positions which appeared capable of conclusive proof.

At the present time the two largest divisions of the Empire, Canada and Australia, though actually separated from each other by only the Pacific Ocean, were telegraphically separated by but little short of the whole circumference of the globe. Both countries had growing interests upon the Pacific; both were manifestly destined to become great powers bordering upon that ocean; and both looked forward to an increased commercial intercourse with each other. Circumstances might easily arise in the near future which would make it of the greatest consequence that these two countries should be prepared to exercise their influence jointly in order that it might be exercised most effectually. Obviously for either closer commercial relations or for joint action, better telegraphic connection was all but an absolute necessity. The cost of sending messages from Canada to Australia was now prohibitive for all practical purposes; with a wire traversing the Pacific it would be reduced to the lowest possible figure, since the line would be fully employed as an alternative route for European messages to and from the South Pacific. Australians should remember, too, that easy and cheap communication with Canada meant the same with the whole continent of America, so closely were the Canadian and the American systems connected with each other.

When he brought this subject before the Colonial Conference of 1887, he proved by arguments and figures which had never yet been refuted, that the cost of sending messages between Great Britain and Australia over the proposed Pacific line would be far cheaper than by any existing route. Since that time the cost of sending such messages had been reduced one-half, and yet the cost per word by the Pacific route as then stated would be little more than one-half of the present reduced rate by Eastern routes. The calculations on which this estimate was based would be found in memoranda submitted to the Conference, and in the discussions thereupon. Any considerable cheapening of telegraphic rates would immediately react upon commercial prosperity and activity.

Turning now to trade defence the subject assumed a new importance. The highest naval authorities were agreed that in time of war the use of the telegraph would furnish one of the most effective means of giving security to the vast commerce of the Empire. Telegraphic orders sent out confidentially by the Admiralty from time to time would indicate to merchant ships the precise course which they should take on both outward and inward voyages. By this means the protecting naval force could be disposed with complete knowledge of the whereabouts of the commerce to be defended, while an enemy would have no such knowledge. It was believed that by making at intervals changes in the routes indicated, greater security could be obtained. To no part of the commerce of the Empire would such a device for protection be so serviceable as to that of Australasia. Without taking into account the new route by way of Canada, which, in emergency, might be used for commercial purposes; if they took into consideration the alternative routes open around Cape Horn and the Cape of Good Hope, and the vast ocean spaces to be traversed, it would be seen that this system might give to Australasian trade an almost complete immunity from attack except in the immediate neighbourhood of European waters, where the strongest force would be available for its defence; merchants and shippers would readily understand that among other advantages there would result an enormous money saving from reduced risks and insurance charges. But the execution of any such plan manifestly depended upon the completeness and security of a national telegraph service around the globe. A glance at a telegraphic map of the world showed that at present we had no such complete and secure service. England had four possible main lines of connection with the East and Australasia. One went by way of Gibraltar, Malta, Egypt, and the Red Sea. Another passing through France, Italy, and Greece, also went on to the Red Sea. A third traversed Germany, Austria, Turkey, Russia, and Persia. A fourth crossed Russia to the Pacific, whence it connected to the South with Chinese and Indian lines. Perhaps the route now completed around Africa should be mentioned as a fifth alternative. But with all these lines it was for national purposes in time of war a fatal defect that they passed through possibly hostile countries, where they would be useless to us, or through shallow seas where the cables could be easily fished up and destroyed. For issuing instructions, such as have been mentioned, to the merchant ships of our Southern Colonies and our Eastern dependencies, not one of these Eastern lines could in time of war be depended upon for a single day. A line across the Pacific, on the other hand, would not only be far removed from the political storm centres of the European continent, but would have two other great advantages—first, it would pass entirely over British soil, and, second, that it would pass chiefly through deep seas where it could only be destroyed with great difficulty. It would complete the circle of communication around the Empire. From a strategic point of view, then, the value of such a line in time of war would be immeasurable. So striking seemed the necessity for its construction that we might fairly argue that even if the line were for a time commercially unprofitable, the Governments of the Mother Land and the Colonies would be fully justified in bearing a portion of the expense, for the sake of the added guarantee of national security which it would give.

The importance attached to the question of a Pacific cable by the Colonial Conference of 1887 led to the following minutes being unanimously assented to and recorded in the proceedings:—

"1st. That the connection recently formed through Canada from the Atlantic to the Pacific by railway and telegraph opens a new alternative line of Imperial communication over the high seas and through British possessions, which promises to be of great value alike in naval, military, commercial, and political aspects.

"2nd. That the connection of Canada with Australia by direct submarine telegraph across the Pacific is a project of high importance to the Empire, and every doubt as to its practicability should, without delay, be set at rest by a thorough and exhaustive survey."

Following up these, and more specific representations of the members of the Conference, the Admiralty was induced to undertake a nautical survey to test the practicability of the route. The survey had been carried on during the intervening years. The soundings were all that could be desired, proving as they did the existence of a sea floor probably not less favourable for cable laying than that of the Atlantic which was used for this purpose. That the results of the survey were satisfactory might be judged from the fact that sounding operations had been closed, and the Admiralty had taken possession of a number of islands in the Pacific for the purpose of establishing mid-ocean stations whenever they might be required. The Canadian Government had, on more than one occasion, indicated its willingness to give substantial support to this scheme of telegraph connection across the Pacific with Asia and Australia. At one time it had arranged for a special deputation to proceed to Australia to confer with the Governments of the various Colonies upon this and kindred subjects, the chief member of the deputation being the present Premier of the Dominion, Sir John Abbott. The delay in sending this deputation was entirely due to the occurrence of political movements in Australia, which seemed to render the time chosen inopportune.

Canadians might fairly claim that they had some right to press the matter of cable extension on the Pacific from a national point of view, since such an extension would be the natural complement of what they have done towards British consolidation. He might be pardoned for pointing out on behalf of Canada that it was in the genuine spirit of British enterprise that she desired to stretch out her arms to Asia and Australia. Had not Canadians been associated from the first with the development of the great modern means of inter-communication? The man was yet alive who projected and took no small part in establishing the first Atlantic cable, and that man, Francis Gisborne, continued to serve the Canadian Government as superintendent of telegraphs. While he pointed with some pride to what had been done by Canada and by Canadians, they all recognised similar evidences of national spirit and enterprise in Australia and New Zealand, indeed throughout the whole Colonial Empire. If we were to keep the Empire intact, if we were to combine all the parts into a lasting whole, we must connect the units by commerce and by every cord of attachment. To extend, expand, strengthen, consolidate, build up, and maintain the new united Empire we must, without delay, take means to obtain the freest and best intercourse between all the parts.

THE HARTMANN AND BRAUN LEAKAGE INDICATOR.

Messrs. Hartmann and Braun's new form of earth leakage indicator is, in outward appearance (see Fig. 1), like an ordinary voltmeter. With a constant difference of potential between the terminals, the readings can be taken direct in ohms; the readings of an instrument designed for a 2,000-volt circuit ranging from 2 megohms to 0·2 megohm. This range can be diminished to suit users' convenience.

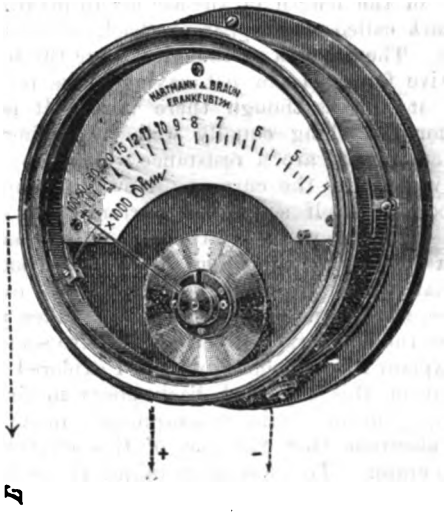

FIG. 1.—Hartmann and Braun Leakage Indicator.

The instrument is connected up as follows:—Terminal E (Fig. 2) is joined to earth. The terminals marked + and − are joined to the leads to be tested. By means of the lever L either lead can be connected to earth through the coil C. If the opposite lead is leaky a current will flow to earth *vid* coil C,

Digitized by Google

which will give rise to a deflection, which, with a constant pressure at the instrument terminals, will be proportional to the conductivity of the fault. These indicators may be used either

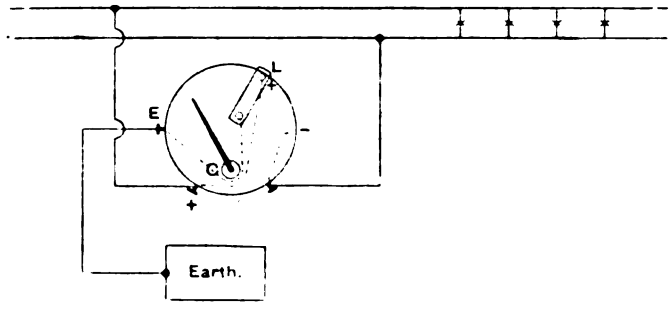

Fig. 2.—Hartmann and Braun Leakage Indicator. Diagram of Connections.

with direct or alternate currents, and all parts are highly insulated, the coil itself being soaked in paraffin wax. Messrs. O. Berend and Co., of 61, Fore-street, E.C., are the English agents for the sale of these instruments.

ON THE PHYSICS OF THE VOLTAIC ARC.*

BY PROF. SILVANUS THOMPSON, F.R.S.

What I have to say relates to the electromotive force of the voltaic arc. If you measure with a voltmeter the difference of potential between the two electrodes of the arc, you find, when the arc is steady, the total voltage so observed is something over 40 volts, and it is known that part of this varies with the length of the arc and the current sent through the arc, and that part is practically independent of either the current or the length. There is a constant part and another part, which varies nearly directly as the length of the arc when the current is constant, and nearly inversely as the current when the length of the arc is constant. A useful approximate formula for the steady arc is $v = a + b\frac{l}{i}$, where a and b are constants, l the length of the arc, and i the current. The constant a varies between 35 and 39 volts; whilst when l is given in millimetres and i in amperes the constant b has values between 8 and 18.

Now, this constant part of the voltage, which is independent of the strength of the current for an invariable length, and independent of the length of the arc for an invariable current, is sometimes called the apparent back electromotive force of the arc. The arc acts as though it were the seat of a back electromotive force. I am not saying there is actually one, only that it acts as though there were. It is possible to account for the thing equally well by saying that there is somewhere in the arc a resistance which proportions itself always inversely to the current. Now, how can any resistance proportion itself so to the current? It can only do so in the following way:—If there is at any one surface of the arc a something equivalent to a transition resistance, then if that varies inversely with the area over which it takes place, and if the area over which it takes place is proportional to the current, then you might have something of the kind to explain this. Some years ago I explored the question of the seat of this supposed back electromotive force, and established, by means of the measurements made with a third moveable electrode, that the seat of this electromotive force was at the crater. This was when taking the ordinary method of producing the arc between two carbon electrodes, an upper and a lower. I explored where the great drop of potential, 35 to 39 volts, occurred. I found that the drop of potential along the arc only amounted to a few volts, and where the great drop took place was at the surface of the positive electrode or crater. This is where most of the work of the arc is done. That being settled as to position, the next question was, what was the physical process going on there which would require such absorption of energy which made this great fall of voltage, and I could only account for it at the time by supposing that the volatilisation of the carbon required it. I was led to this by various reasons, one being Captain Abney's discovery that the surface of the crater is always of an equal intensity; the brilliancy for the same quality of carbon per square centimetre was always the same. I was led by that to think it must be simply a question of volatilisation.

Quite recently, however, Mr. Crookes has made the observation that the flaming discharges produced by alternating electric currents at very high rates of alternation and very high voltage are really endothermic flames of nitrogen and oxygen; in other words, those flaming discharges are simply flames which, instead of giving out heat, absorb heat. Now, in the voltaic arc, as produced in air, something of this kind may occur. There must be a temperature high enough to bring about for the time being the combination of nitrogen and oxygen. We know from Prof. Dewar that such combinations are going on. The question consequently occurred to me whether this had anything to do with the voltage of the arc; and within the last month I have made a number of experiments to put this particular point to the test. A number of experiments were made in my laboratory to test whether the possible combustion of nitrogen and oxygen together had anything to do with the electromotive forces there observed. We did this by surrounding the arc by a glass tube, into which we could introduce a number of gases, say oxygen, nitrogen, carbonic di-oxide, hydrogen, and so forth. Using always short arcs, and waiting until the current was adjusted to 10 amperes and the arc adjusted to the exact length, we found it does not really make one volt difference. The back electromotive force, or whatever it is, is independent of the surrounding atmosphere.

Incidentally we have observed several effects, namely, that when chlorine and carbonic oxide are used as the atmosphere in which to produce the arc, the crater takes a quite different form from that of the usual arc. The carbon is flattened over the end instead of hollowed, and the negative carbon is also a very obtuse cone. Also when the arc is made with hydrocarbon or coal gas around it the crater is formed, but the edges do not burn away as they do when the arc is made in air. Consequently, there is a regular sooty deposit all round, and the arc is formed up inside a sort of cage. When the arc is made in oxygen, both the carbons burn away very fast. Instead of their ordinary consumption there is an extraordinary consumption which burns them down conically a long way. We have also observed in bringing these gases to the outside of the arc it is necessary that they be introduced gently, without violent draughts, because with even a gentle current of gas the voltage is altered. By blowing on an ordinary arc in air the voltage has been made to rise to as much as 75 volts.

The experiments were conducted by Mr. Eustace Thomas, one of the demonstrators, and by Mr. Portheim, one of my students, to both of whom my thanks are given. There still remains much to do in measuring with exactitude the small variations which may be due to endothermic actions.

* Paper read before the British Association, in Section A, Edinburgh, August, 1892.

THE EWING MAGNETIC CURVE-TRACER.

The following is a report of the discussion which arose after Prof. Ewing's description of his Magnetic Curve Tracer, an account of which appeared in our issue of August 12th:—

Dr. JOHN HOPKINSON: Some experiments that my son has been making for me during this spring will, I think, give an answer to one question which Prof. Ewing has put forward, as to whether the curve of cyclic magnetisation is the same when gone through rapidly as when it is gone through slowly. The experiments were done in a perfectly simple and straightforward way, with a transformer made of very fine wire $\frac{1}{100}$in. in diameter, the wire being varnished before being wound. The experiments were performed both with soft iron wires and with hard steel wires. First of all, the curve of cyclic magnetisation was determined when the instrument was used simply as a transformer. It was done by a make and break arrangement, by which the E.M.F. could be measured at-

Digitized by Google

any time in the cycle. Then the E.M.F. curve was integrated, and the integral of that curve gave us the induction. The cycle was gone through with great rapidity, about 100 periods per second. The slow period was done in the way Prof. Ewing made use of long ago. The two curves were then compared. We found a difference. When the cycle was gone through slowly, the points lay precisely on the curve all the way down; but they deviated a little inside on the lower part of the curve (*see* Fig. 1). That appeared to be the only difference between the curve of magnetisation when gone through rapidly and when gone through slowly. On the return curve, of course, it was exactly the same thing. That was the case both with soft iron and with hard steel. Of course, when we had thicker wires we at once had the influence of Foucault currents in the wire. With a millimetre in diameter it became very appreciable. When we thinned our wire there were no effects from Foucault currents. Again, when we neglected to varnish the wire we at once saw the same effect.

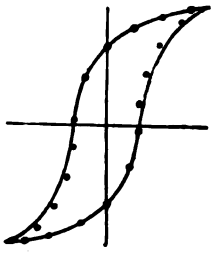

FIG. 1.

A discussion arose in which Lord Kelvin, Dr. Hopkinson, and Prof. Silvanus Thompson took part, with regard to the effect on the magnetic resistance of the transformer circuit of various ways of arranging the core wires, and three diagrams (Figs. 2, 3 and 4) were drawn on the blackboard. Fig. 2 represented a single turn overlapping, and Fig. 3 two turns. Lord Kelvin pointed out that if the wire was coiled as in Fig. 2, the lines of force would have to cross what was practically an air gap of exceedingly small amount, depending on the thickness of the varnish. Dr. Hopkinson thought the effect must be very minute. Prof. Silvanus Thompson suggested that by not bringing the ends round, and joining as shown in Fig. 4, the variations in the curve alluded to by Dr. Hopkinson might be accounted for.

FIG. 2.

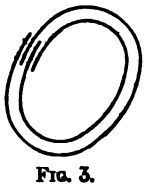

FIG. 3.

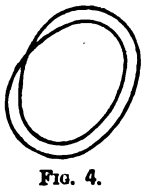

FIG. 4.

Prof. PERRY: When I saw Prof. Ewing's beautiful experiments last night I did hope that it would have cleared up this difficulty, because I understand he has actually got 40 cycles per second, and still got a hysteresis curve something like he showed in his experiments; but I should like to ask Prof. Ewing whether he is quite satisfied that the hysteresis curve is at high frequencies approximately like what it is at low speeds; or does he only expect to find proof by further experiment with much more rigid apparatus and much more rapid cycles?

Prof. EWING: In answer to Prof. Perry's question I am only able to speak positively regarding frequencies up to 20 per second or thereabout. But up to such frequencies as that there is no doubt that the general form of the hysteresis curve remains unchanged. I do not say that there are not changes in detail; it might be a little wide, might have such changes as Dr. Hopkinson spoke of just now; but the general character of it remains unchanged. The peculiar double letter S with sharp corners is certainly there, and the first influence of increase of speed beyond a certain limit, the first obvious effect, is the rounding off of the corners. It is well known, as Dr. Hopkinson has mentioned, that this is one of the effects of eddy currents in the iron itself, and how far this distortion which I have noticed taking place at a speed exceeding 20, is due to eddy currents I am not able to say. I believe from the dimensions of the laminated iron I used last night there might have been some distortion due to this cause. In the other instrument, where the bars are thick, it is not possible to perform even a reasonably good cycle at such a speed as one cycle per second, not, as has been suggested, on account of the mechanical inertia at all, but on account of what we may call the magnetic inertia. It is altogether a magnetic phenomenon. I have had some previous experience of time lag in other experiments, but I was altogether unprepared for the effect in this. Even when we attempt to go through the cycle at the rate of, say, one per second with these thick bars, the curve immediately takes up a form with no sharp corners at all, the area is greatly increased, and the maximum lies much inside of the end. At a little higher speed it becomes practically a sort of inclined ellipse. This cannot be an effect of mechanical inertia at all, as you can easily see by testing for dead-beatness in other ways, or by substituting fine wires with which it is possible to reach a speed of 10 per second or more without distortion. The interesting point is this—that this magnetic sluggishness occurs with thick bars, especially with soft iron in an annealed state, and it occurs, I think, to an extent which it is very difficult to ascribe to the presence of Foucault currents. I am rather inclined to ascribe it to a result I mentioned here two years ago, a genuine magnetic time lag, due to the molecular displacement which is consequent on the magnetisation taking place in the following manner:—Suppose we have a very homogeneous material to deal with, in which the molecules are arranged with great regularity, then those which yield first to the magnetic force will be the outermost ones, for the molecules on the surface are less constrained by neighbours than those inside. The disturbance of them precipitates the remainder into a state of instability, and so we have the process of magnetisation creeping into the interior from the surface. The kind of time lag exhibited in this way can very easily be seen by means of the model magnets I showed last night. If we are dealing with a thick bar, there is a great distance relatively for the magnetic disturbance to travel into the interior from the surface where it begins; but if we are dealing with a very laminated material, then we have ever so many more points subject to the surface conditions, and therefore capable of serving as origins of disturbance, and so the whole mass takes its magnetism much more rapidly than in the case where it lies far away from the surface points. I think the sluggishness which the thick bar shows is due as much to this cause as to the eddy currents.

THE NOMENCLATURE OF ELECTRICAL UNITS.

The following is a report of the discussion on the Nomenclature of Units, which took place at the recent meeting of the British Association in Section A on Tuesday, August 9th:—

After some remarks by M. GUILLEAUME on a proposed unit of radiation and of pressure,

Dr. JOHN HOPKINSON: I think we ought to be exceedingly cautious in the adoption of new names for units and so on, especially when a science is in the state of rapid development in which practical electrical science is at the present time. We have, I think, in some of the proposals of Dr. Lodge to-day a very good illustration of the somewhat premature adoption of particular names for particular purposes, for now he proposes to alter the signification of the terms already adopted. It seems to me, too, that we should be still more cautious in altering the names already fixed. In looking through the proposals of Dr. Lodge, we find first of all he proposes to alter the meaning of the word "farad." He wants to call that which has hitherto been called a microfarad a farad. That, to my mind, is open first of all to the objection that we should always have to refer to the date at which a Paper has been written to know the signification of the term. It is true that in many cases from the context we might ascertain what was intended; but cases might arise in which it would be difficult. That would, to my mind, be a great objection to altering the meaning of a term, even if it be clear that it is desirable to alter it, which in this case I greatly doubt; for, looking to the future, it is quite conceivable that we may be able to manufacture and cheaply manufacture, condensers or quasi-condensers of capacities comparable with a farad under the old acceptation of the term. Is it not possible that we may get liquid condensers or quasi-condensers which will have considerable capacities? We certainly can make such condensers; the only objection to them is that they are wasteful in power. That difficulty may be got over. If it is we shall have condensers of a capacity of one farad, and if Dr. Lodge has altered the signification of the term we shall have megafarads, which will be matters for every-day discussions as micofarads are now. I see Dr. Lodge has dropped his proposals with regard to the coulomb and the watt. With regard to the magnetic circuit, he calls attention to the fact that there are three names used with regard to the coefficient of self-induction, the secohm, the quadrant and the henry. I confess for my own part a great preference for the name quadrant, for that is a name purely and simply for a length. Coefficient of self-induction *is* a length and nothing else but a length; why then should we call it anything else than a length? You may measure it in yards or metres or what unit you please; the actual unit we do use is the quadrant of the earth's parallel longitudes. Then there is another proposal of Dr. Lodge's, from which I dissent. He proposes we should use the weber as the unit of total induction. Well, that to my mind would be quite unobjectionable if the weber in the past had not been used in a totally different signification. Not so long since it was used as the unit of current, and if we give it a new signification, we shall have to know the date at which a Paper was written in order to know the real signification of the term. One would willingly do honour to the name of Weber; at the same time if we are to adopt a name for this unit, which I doubt at the present time, we ought to take some other name. The last point I would like to remark upon is on the proposal made with regard to "mo." Well, there it is, not that I object to the adoption of a name, but this I do feel that it is a very doubtful name to adopt. I think scientific men may go the length possibly of manufacturing mongrel names compounded out of two or three or more languages without doing any great violence to their feelings. They might, no doubt, subject themselves to the hypercriticism of the linguists. But there is a point beyond which we ought not to go, and I think if one imagines the sensitive feelings of the linguistic gentlemen harrowed as they would be harrowed by seeing the words actually turned inside out, one feels we should desist and take some other term for the reciprocal of resistance.

Mr. W. H. PREECE: I am afraid Dr. Hopkinson forgets that the word "mho" is almost historical. It was proposed some years ago by Sir William Thomson to represent the reciprocal of resistance, and it is in frequent use, and there are instruments at the present day known as mhometers. I do not object to the word "mho." What I do object to is Dr. Lodge's way of spelling it. It is a very bad habit to drop our *h*'s.

Digitized by Google

"Mho" has a significance, and it may be that it conveys an idea. There is another proposal to which I have no objection, and that is the transference of the term "farad" from the very large unit originally proposed to the smaller one proposed by Dr. Oliver Lodge. It happens, fortunately, that in literature and in papers generally the index ϕ, the Greek letter, is used very much indeed to indicate the unit of capacity, and it matters not whether that ϕ be called a microfarad or a farad. In my experience I have never known a single case of the word "farad" being used. It is infinitely greater than anything in use. It may be that in the dim future Dr. Hopkinson sees the possibility of using these enormous quantities, but that time is not yet. It would be just as easy to call them megafarads as it is to speak of megohms. I think there would be an advantage in converting the term microfarad into farad. Dr. Oliver Lodge has said I spoke favourably of this change. I did so, because it was consequent on another change which is, to my mind, of far greater significance than any other proposal of Dr. Lodge's. It is that the value of the unit of electromotive force should be raised from 10^8 C.-G.-S. to 10^9. Now, if we were to raise the unit of the electromotive force by one more power of 10, we should at once place the practical units that we use most frequently on the same line exactly as the C.-G.-S. absolute system of units. Although I do not now propose it, I shall do so next year. At the Congress we hope to hold at Chicago I shall make it a distinct proposal that the unit of electromotive force shall be increased from the power of 8 to the power of 9. Dr. Lodge has dropped nearly all his more revolutionary proposals. I rather think the time has scarcely come when we can apply to the unit of magnetic field or magneto-motive force any name. Names are of immense consequence when we really know the thing to which we are going to apply them, when we are absolutely decided on the very thing we are going to deal with. We are not quite clear yet on the points of what may be called "gaussage," "weberage," or "lodgage," and a few other things, and we certainly shall have to postpone the final discussion of these matters until we have the results of a Congress, which I hope will have very great results indeed—the Congress next year at Chicago. Therefore I only agree with Dr. Lodge in the proposal that the term farad be applied to the present microfarad. He suggests ampere-hour as a convenient term for quantity. Ampere-hour is one of the most convenient units we have. It has not a name, and it does not want it.

Prof. DU BOIS: I can only say that, as far as I interpret the feeling of Continental physicists, I know that if these names are introduced here they will not be used at all on the Continent.

Dr. LODGE: I am sorry Prof. Du Bois does not agree with the gauss and the weber; I thought the Germans, at any rate, would agree with that.

The PRESIDENT (Prof. Schuster): I am sorry the time is so short, and the number of units so large, that there is only an infinitesimal amount of time for each. I sympathise to a great extent with Mr. Preece's difficulty. Whether it is possible to alter now or not I cannot say—that is a very different question; but the inconvenience of the factor 10 is enormous. The units in which I am specially interested—and I hope they will not be dropped—is the question of introducing some form or other of C.-G.-S. unit of pressure. The fact is certainly remarkable that M. Guilleaume first pointed out that 75 cm. of mercury are, as far as we can tell, exactly 1 megadyne per square centimetre. That is a useful thing to know, and the 75 centimetres deserve some recognition and some name. I think the introduction of the word "atmosphere" would be a great help; but there is not any time to enter into that now.

REPORT OF THE BRITISH ASSOCIATION ELECTRICAL STANDARDS COMMITTEE.

The work of testing resistance coils at the Cavendish Laboratory has been continued. A table of values found for the coils is appended. The committee have ceased issuing standards in terms of the legal ohm of the Paris Congress. As will be seen from the table, most of the coils tested are ohms as defined by the resolutions of the committee, and the Electrical Standards' Committee of the Board of Trade. (*See* B. A. reports, 1890 and 1891.) According to these,

1 B. A. unit = 0·9866 ohms.
1 ohm = 1·01358 B. A. unit.

B. A. Units.

Elliott, 0·230 80		1·00016	14·4°

Of the ohm coils the three first in the table have been tested before (Report 1891) it was thought desirable to reissue the certificates in terms of the new ohm standards. A large number of the other coils were constructed as legal ohms, hence the values of the resistance given in ohms at temperatures of 14deg. or 15deg. are low. The coils in many cases are very nearly legal ohms at the temperature given, while they will be ohms some 8deg. or 10deg. higher.

In addition to the coils given in the table, four ohm coils, constructed by Messrs. Elliott Bros., for the Board of Trade, were tested very carefully. Some fourteen or fifteen comparisons were made for each coil at temperatures between 9deg. and 18deg., between June, 1891, and January, 1892. The coils were compared directly with the B.A. unit, "Flat," the difference being expressed in terms of the bridge wire; while in another series of observations a coil of resistance, 100 ohms, was put in multiple arc with the ohm standard, and the difference between flat and the combination found; in this case the length of the bridge wire used was small, and the possible error arising from uncertainty as to its exact temperature was avoided; that this error was very small was proved by the fact that the two sets of observations gave practically identical results.

The following are the results:—

Elliott	261 ... 300 ...	$1 - 0{\cdot}000309\ (t - 15{\cdot}35)$
„	262 ... 301 ...	$1 - 0{\cdot}000310\ (t - 15{\cdot}35)$
„	263 ... 302 ...	$1 - 0{\cdot}000300\ (t - 15{\cdot}4)$
„	264 ... 303 ...	$1 - 0\ 000312\ (t - 15{\cdot}4)$

In the case of two of the coils, Nos. 261 and 263, there was one observation for each, which differed from the value given by the above curve by 0·00015 ohms, and this was due to the fact that the ends of the coils had got dirty and needed amalgamation. None of the other errors in the sixty observations exceeded 0·00008 ohm, and there were only eight which were as great as 0·00005. Thus the resistances of these coils are known in terms of the B.A. Standard to a very high degree of accuracy.

During the year Messrs. Elliott Bros. have supplied the committee with two 1-ohm and two 10-ohm standards—the tests of these are in progress; two 100-ohm standards are on order. Messrs. Nalder Bros. are also constructing some standards. The Fleming bridge, belonging to the Association, has been put into thorough repair; the mercury had damaged some of the copper connecting pieces.

The secretary and Mr. Skinner have continued during the year their experiments with Clark cells. These have been communicated to the Royal Society, and the Paper is being printed in the *Phil. Trans.*

They find that the E.M.F. of their standard cell is 1·4342 volts at 15° C., while cells set up by Lord Rayleigh in 1883-1884, Mr. Elder in 1886, Mr. Callendar in 1886, Dr. Muirhead in 1890, Dr. Kahle, of Berlin, Dr. Schuster, Mr. Wilberforce, Mr. Griffiths, and these in 1891 and 1892, agree closely, the variations among them all being very rarely greater than 0·0005 volt.

During the Edinburgh meeting the committee were honoured with the presence of Dr. von Helmholtz, M. Gilleaume, of Paris,

Digitized by Google

Prof. Cahart, of the United States, Dr. Lindeck and Dr. Kahle, of the Berlin Reichsanstalt. These gentlemen came by invitation to consider the question of establishing identical electric standards in various countries, and two meetings of the committee were held, at which discussions took place. Major Cardew, of the Board of Trade, was present, and took part in the discussion. Dr. von Helmholtz drew special attention to the need for having a unit of resistance defined in terms of a specified column of mercury, and pointed out that the difficulty arising from the uncertainty of the relation between the centimetre and the gramme might be avoided by defining the mass of mercury column of given length, which has a resistance of 1 ohm. After discussion, the following resolutions were agreed to :—

1. That the resistance of a specified column of mercury be adopted as the practical unit of resistance.

2. That 14·4521 grammes of mercury, in the form of a column of uniform cross section, 106·3cm. in length, at 10°C., be the specified column.

3. That standards in mercury or solid metal having the same resistance as this column, be made and deposited as standards of resistance for industrial purposes.

4. That such standards be periodically compared with each other, and also that their values be redetermined at intervals in terms of a freshly set up mercury column.

It was further agreed that these resolutions should be communicated to the Electrical Standards Committee of the Board of Trade.

With regard to the units of current and of electromotive force, it was agreed that the number of ·001118 should be adopted as the number of grammes of silver deposited per second from a neutral solution of nitrate of silver by a current of 1 ampere, and the value 1·434 as the electromotive force in volts of a Clark cell at 15°C.

Dr. von Helmholtz expressed his full concurrence in these decisions, which are, as he informed the committee, in accord with the recommendations which have already been laid by the Curatorium of the Reichsanstalt, as well as by himself before the German Government.

The committee wish to place on record their thanks to Dr. von Helmholtz and the other visitors for the help they have afforded them in coming to so satisfactory a conclusion.

Dr. Lindeck laid before the committee some information as to the properties of the manganese alloy used at the Reichsanstalt for resistance coils, and it was agreed that it was desirable to obtain copies of the German standards in manganese for further comparison with the standards of the Association. The committee, therefore, recommend that they be reappointed, with the addition of Mr. Geo. Forbes, and with a grant of £25, including an unexpended balance of £10. That Prof. G. Carey Foster be Chairman, and Mr. R. T. Glazebrook, Secretary.

Appendix I.

Information Circulated by the Secretary for the Meeting of the Committee on August 4th, 1892, with Additional Notes.

The report of the Electrical Standards Committee of the Board of Trade is printed in the B.A. Report for 1891. Further information as to the values of the units is given in the B.A. Report for 1890. The following summary may be of use.

The Board of Trade Committee recommended for adoption the values ·9866 and 106·3.

The specfic resistance of mercury in ohms is thus :—

$$\begin{aligned} &\cdot9407 \times 10^{-4} \\ \text{Also 1 Siemens unit} &= \cdot9407 \text{ ohms.} \\ &= \cdot9535 \text{ B.A.U.} \\ \text{1 ohm} &= 1{\cdot}01358 \text{ B.A.U.} \end{aligned}$$

The results found by Lord Rayleigh were originally reduced by the use of the value for the specific resistance of mercury in B.A. units found by him. If, instead, we use the value 0·9535, the mean of the best determinations, there we have for the length of the mercury column having a resistance of 1 ohm, the values 106·27 and 106·31.

At the meeting of the committee M. Guilleaume stated that a correction should be made to M. Wuilleumeier's value, which would raise it to 106·31. This arose from some uncertainty as to the correction required to the resistance of mercury for change of temperature, a question on which M. Guilleaume had been working lately. Taking these corrections and omitting the value found by Prof. Wiedemann in accordance with the criticisms of Prof. Dorn, communicated by Dr. von Helmholtz, we arrive at 106·31 as the mean result.

2.—*The Electrolysis of Silver.*

The following values have been found for the mass of silver deposited from a solution of silver nitrate in one second by a current of 1 ampere :—

Glazebrook and Skinner, *Proc. R.S.*, LIV., 1892 1·4342 „

A comparison has been made between the standards of the Association and the Berlin standards through a Clark cell and a resistance coil belonging to Dr. Schuster. By the kindness of Dr. von Helmholtz, the secretary hopes to have a direct comparison between the two sets of standards completed before the meeting (*see* Appendix III.).

Appendix II.

On the Values of Certain Standard Resistance Coils.

By R. T. Glazebrook, F.R.S.

In the report of the committee for 1890 it was stated that during the early part of the year small changes had taken place in the values of some of the old B.A. standards which had been subjected to a very low temperature early in that year. These coils have been compared together at intervals since that date, and the following tables will show that at the temperature given there is no indication of any further change. The difference between the coils and the standard coil flat is given in bridge wire divisions. The value of one bridge wire division is about 0·00005.

The first few lines in each table give the values of the differences observed in 1890. These are followed by those of the more recent observations which were taken at a temperature of about 16deg.

Digitized by Google

Table I.—*Showing the Differences between the Platinum Silver B.A. Units in 1890 and 1892.*

Date.	Temperature.	Flat—F.	Flat—G.	Flat—H.
May, 1890.....	14·4	−3·5	21·5	18·3
June, 1890	16	−3·2	22·2	17·8
August, 1890 ...	16	−3	22·6	18
July 23, 1892	16	−3 7	21·6	18·4
July 24. 1892.....	16·5	−3·5	22	18·3
July 27, 1892.....	16·2	−3·2	21·6	18·3

These observations are sufficient to show that there has been no appreciable change in the relative values of these coils.

The observations on the legal ohm standards given in Table II. lead to the same conclusion.

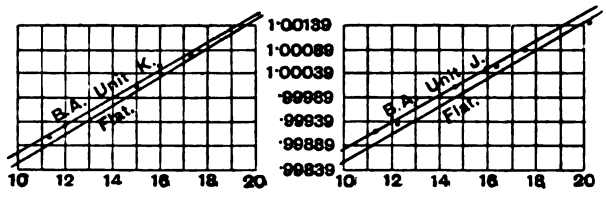
August, 1890	15·7	216·7	206·6
November, 1890	15	217·2	206·7
January, 1891	11·6	216·1	206·8
July 25, 1892	16·3	215·6	205·8
July 27, 1892	16·1	216·0	206·3

In November, 1890, two new coils, marked J and K, were made of platinum-silver wire supplied by Messrs. Elliott Bros. The wires of the coils are wound in a loose spiral inside the case, being secured at intervals by silk threads to an ebonite central stem. They are thus in contact with air only, and there is no paraffin inside the case. It was hoped in this way to secure freedom from the strains set up by changes of temperature in the paraffin which appeared from the results given in the report for 1890 to have some connection with the changes of resistance there described.



Values of the B.A. Units Flat, J and K.

From observations between November 1890, and July 1892.

The vertical divisions are 0·00005 B.A.U. ; the horizontal divisions are 0·1° C. Flat = 1 B.A.U. at 14·8°, temperature coefficient 0·000277 (Fleming's observations, 1876) ; J = 1 B.A.U. at 14° temperature co-efficient 0·000260 ; K = 1 B.A.U. at 14·15° temperature co-efficient 0·000261.

From the six observations for each coil recorded it is clear that there has been no change during the time for which the observations have lasted.

Two observations were made at a much lower temperature, and these would seem to indicate a slightly less temperature coefficient than is shown by the observations between 10deg. and 20deg.

The values of the two new coils in B.A. units between temperatures of 10deg. and 20deg. are given by

$$J = 1 + 0{\cdot}000260\,(t - 14)$$
$$K = 1 + 0{\cdot}000261\,(t - 14{\cdot}15).$$

We may thus conclude that during the past two years there has been no relative change in the values of the platinum silver unit standards of the Association.

Four of these are the original standards made in 1865-67, two others were made by Messrs. Elliott Bros. in 1885, and the last two by the assistant at the Cavendish Laboratory from wire supplied by Messrs. Elliott in 1885.

Appendix III.

On the Values of Certain Standards of Resistance and Electromotive Force sent from Berlin for Comparison with the B. A. Standards.

Towards the end of July Dr. Lindeck, of the Physikalischi Technische Reichsanstalt, at Berlin, brought to Cambridge three resistance coils of nickel manganese copper alloy, in order to compare them with the B.A. standards.

Experiments to determine the value of these coils in terms of the resistance of mercury are in progress at Berlin. When they are completed a comparison of the B.A. units with the mercury standards of the Reichsanstalt will become possible.

A fourth coil, constructed for the Berlin Reichsanstalt by Messrs. Elliott Bros., was also tested. Table I. contains the results.

Table I.

No. of coil.	Date.	Temp.	Value in B.A.U.	Mean value of series.
Wolff 150	July 25	15·5	1·01118*	
	„ 27	17	1 01116	
	„ 25	16·5	1·01119*	1·01118 at 16·7°
	„ 26	16·3	1·01119	
	„ 27	17·1	1·01120	
Wolff 139	July 25	16·5	1·01110*	
	„ 27	16·9	1·01112	
	„ 25	16·5	1·01110*	1·01112 at 16·7°
	„ 26	16·3	1·01114	
	„ 27	17·1	1·01116	
Wolff 147	July 25	16·5	1·01112*	
	„ 27	16·9	1·01112*	
	„ 25	16·5	1·01113*	1·01113 at 16·7°
	„ 26	16·3	1·01112	
	„ 27	17·1	1·01115	
Elliott 250	July 25	17	1·01107*	
	„ 27	17	1·01107*	
	„ 28	17	1·01108	1·01107 at 17°
	„ 29	17	1·01108	

In the experiments marked thus * a considerable length, 200 cm. of the bridge wire, was used. An error of 1° in the temperature of this would produce an error of ·00003 in the result. In reducing the results the temperature of the bridge has been taken at 18°, the value given by a thermometer laid alongside the wire on July 28th. In the other experiments a coil of 100 ohms was put in multiple, as with the Berlin Standard, and the difference of the combination and the B.A. Units was found.

The length of bridge wire was very small, so that an exact knowledge of its temperature was not wanted, while the 100-ohm coil was known with all the necessary accuracy.

Another set of comparisons leading to results which do not differ from the above by more than ·00003 B.A. units were made by Dr. Lindeck, using apparatus he had brought from Berlin ; but a complete discussion of the whole can best be given when the values of the Berlin coils have been found. Dr. Lindeck also brought four Clark cells. Of these two, Nos. 69 and 71, were of the pattern described by Dr. Kahle, *Electrotechnische Zeitschrift*. July 22, 1892. *Zeitschrift für Instrumentenkunde*, Ap., 1892. The mercurous sulphate is enclosed in a porous pot, its zinc dips among the crystals of the zinc sulphate, its end being bent so as to be horizontal. The vertical portion of the zinc is covered with a glass tube, so that the horizontal part alone is effective. The other two, Nos. 12 and 29, were H cells of the pattern described by Lord Rayleigh.

These cells were compared with the Standard at the Cavendish Laboratory with the results shown in Table II., which gives the differences between the four cells and the standard in hundred thousandths of a volt.

Table II.—*Values of Berlin Cell. Standard in ·00001 volt.*

Date.	July 26th.	July 27th.	July 29th.
Temperature.	16·1	15·9	15·9
Cell No. 69	−15	−18	−14
„ „ 71	−11	−15	—
„ „ 29	−36	−35	−36
„ „ 12	−39	−38	−39

On July 29th, cell No. 71 had been taken away.

Dr. Kahle kindly determined the differences between No. 69 and each of the other cells before they left Berlin. Values for these same differences can be obtained from the above Table II.

We thus get Table III.

Table III.—*Differences between Cell 69 and the others sent from Berlin.*

Date and place of observation.	No. 71.	No. 12.	No. 29.
July 19, 1892, Berlin	−2	29	29
„ 20, „	−4	28	25
„ 21, „	−4	25	26
„ 26, „ Cambridge	−4	21	24
„ 27, „	−3	19	20
„ 29, „	—	22	25

Thus the relative values of the cells as found at Cambridge are practically the same as those found at Berlin, while taking

Digitized by Google

the E.M.F. of the Cambridge standards as 1·4342 volts at 15deg., that of the Berlin cells with porous pots is 1·43405 and of the Berlin H cells about 1·4338.

The value actually found by Dr. Kahle for the E.M.F. of the porous pot cells is 1·4341 volts, so that the agreement is complete. In all the above it has been assumed that the resistance of 106·30 cm. of mercury is 1 ohm, and that the amount of silver deposited per second by a current of 1 ampere is 0·001118 gramme.

The H form of cell in all cases examined at Berlin has a slightly lower E.M.F. than those with the porous pots, the difference being about 0·0003 volt.

Appendix IV.

On the Standard Condensers of the Association and on Certain Resistance Coils.

By R. T. Glazebrook, F.R.S.

The report of the committee for 1890 contains as an appendix a very full account of the tests on the standard condensers belonging to the Association. It was there stated that while the insulation resistance of No. I. was very high, that of No. II. was not completely satisfactory. No. II. was, therefore, taken to pieces and set up afresh. Its capacity, and also that of No. I, were determined afresh, using the commutator method described in the previous Paper.

The following values were found :—

Condenser No. I.

Date.	Capacity in microfarads.	Mean of each series.
December 23, 1890	0·021059	0·021050
„ „ „	0·021052	
„ „ „	0·021046	
„ 29 „	0·021044	

Condenser No. II.

December 23, 1890	0·021396	0·021395
„ „ „	0·021392	
„ „ „	0·021399	
„ „ „ afternoon	0·021365	0·021389
„ „ „ „	0·021399	
„ „ „ „	0·021403	
„ 29 „	0·021381	0·021390
„ „ „	0·021409	
„ „ „	0·021389	

Mean of the whole..... 0·021391 microfarad.

The different values in each series correspond to different rates of revolution of the commutator.

The value found originally for the capacity of No. 1 was 0·021024 microfarad ; it would appear, therefore, that it may be slowly increasing. The capacity of No. II. has been changed by being taken to pieces, and from 0·022515 to 0·021391.

The two condensers were also compared directly assuming the value of No. I. to be 0·021050, that of No. II. was found to be 0·021390, practically the same value as that given by the commutator.

As a further check on the values a mica condenser was compared with the two in the usual way. The values found were :—

Date.	In terms of I.	In terms of II.
December 29, 1890	0·5017	0·5013
January 1, 1891	0·5013	0·5012

In March, 1892, the insulation of the condensers was tested by the secretary and Mr. A. S. Bowley ; they were both found to lose rather less than one-six hundredth of their charge per 1 minute.

A divided condenser, Elliot No. 144 C.L.C. No. 3 was compared ; the results are interesting as showing the effect on the capacity of the time of charging, and are given in Table III.

The first observation in each case marked as 0″ was made by connecting the galvanometer, and then momentarily making the battery circuit for a very small fraction of a second. The observations on the condenser, 0·2, show that there has been no appreciable change in the relative value of the Standards I. and II. The observations throughout are accurate to about one part in 10,000.

During the process of the work, Mr. Bowley compared several of the resistance boxes of the Association together ; as these are used as standards in many experiments, it will be useful to put the results on record.

Box Elliott 1,253 is a Wheatstone's bridge box of platinum silver in legal ohms, said to be right at 18°. Assuming that the two 1,000-ohm coils of the bridge are equal, and the experiments showed no appreciable difference, the following values were found for certain coils in terms of a nominal 10,000 ohms taken from 1,253.

Table III.

Nominal value.	Time of charging.	Value in terms of I.	Value in terms of II.	Nominal value.	Time of charging.	Value in terms of I.
0·5	0″	0·05022		0·2	0″	0·2003
	5″	0·05072			2′	0·2018
	10″	0·05080			5″	0·2027
					10′	0·2033
0·5	0″	0·05055			20″	0·2039
	5″	0·05106			30′	0·2046
	10″	0·05109				
0·2	0″	0·1988	0·1981	0·5	0″	0·5032
	2″	0·1999	0·2002		2″	0·5058
	5′	0·2007	0·2009		5″	0·5078
	10″	0·2010	0·2013		10″	0·5081
	20″	0·2012			20″	0·5092

Elliott, 1,825.		Nalder, 1,870.	
Nominal value.	Value found.	Nominal value.	Value found.
10,000	10,012	100,000 No. 1	100,042
20,000	20,024	„ No. 2	100,044
30,000	30,034	„ No. 3	100,050
40,000	40,049	„ No. 4	100,034
		„ No. 5	100,042
		„ No. 6	100,042
		„ No. 7	100,052
		„ No. 8	100,032
		„ No. 9	100,047
		„ No. 10	100,052

The temperature of all the coils was about 15·6 C.

Thus the box Elliott, 1,825, is right at about 4deg. below the box 1,253, while the box Nalder, 1,870, is right at about 1·5deg. below 1,253.

DISCUSSION.

The PRESIDENT : It is a rule of the Association not to discuss reports, but in this instance we may, I think, suspend the rule ; and if Prof. von Helmholtz will make one or two remarks upon this point, we shall be very grateful to him.

Prof. VON HELMHOLTZ said that in Germany they were in very much the same situation which had developed itself here in England with regard to electrical measurements. They had taken part with the delegates of England and other European Governments in the Electrical Congress of 1884, when it was resolved that the French Government should bring the decisions of the Congress to the knowledge of the other European Governments, and ask them to make the results arrived at the legal standards in their respective countries. He believed this communication had been made by the French Government ; but, as far as he knew, no Government had taken any steps under the proposal, not even France itself, so that they were in the same position now that they were in before 1884. It was clear now, eight years having elapsed, that a fresh agreement was necessary. The first Electrical Congress at Paris, which was held in connection with the great Electrical Exhibition there, made proposals as good as could be made at that time. There were very few measurements then made, and several of the delegates to the Congress undertook to make new measurements. Their results were brought before a later Congress. This later Congress was official ; the first was only a private one. They then had to choose between numbers which were different to the extent of 1 per cent. ; at least those which seemed to be of sufficient accuracy were still different by 1 per cent., and they therefore had to choose the middle one of them, which was a mercury column, the proposal of Dr. Werner Siemens, one square millimetre in section and 1 metre 6 centimetres in length, at the temperature of the freezing point. They could not arrive at a more accurate number. That work had been continued in the different countries of Europe, by Englishmen, by Frenchmen, and by Germans, and they had now numbers which agreed far better, so that they might assume that this number of 106·3 was right to about one in ten thousand. Therefore they were now able to give the statement of this value, which would, without doubt, be quite sufficient for all industrial purposes for a long time to come ; and it was a value which would be even sufficient for most scientific purposes. There therefore seemed no reason why the former definitions of the Paris Congress should remain. They had gone on in Germany, and it was considered that it was a task which ought to be performed by the Reichsanstalt, of which he (von Helmholtz) was President, and therefore the matter was brought before the Consulting Committee of the Reichsanstalt at the beginning of this year. They received information about that time of the English proposals, which were made rather earlier, and they found it quite reasonable on the whole to accept the numbers proposed by the Committee of the British Association

Digitized by Google

and laid before the Board of Trade. There were only some special points in which they thought there should be any difference. They had found German silver, like many other alloys, particularly those which contained a little zinc, changed in resistance. If such a wire were wound round a coil it had a larger resistance than before; when it was manufactured its resistance altered within a period of some weeks, or even some months, so that they were never sure if two wires which originally had the same resistance had the same after some months. They found out other alloys, and principally those which had a small temperature coefficient. In using those alloys it was possible to get to a far higher degree of accuracy in comparing resistances than with others. Some of them were not very good for the constancy of their resistance; but after some time they found that an alloy, consisting principally of nickel and copper, had a very small temperature coefficient, and at the same time good mechanical qualities, so that if a new coil were wound, and it was heated several times in boiling water, a constant quality was obtained, and there was no change afterwards. These newer wire coils, made of such an alloy, when compared with mercury standards, were quite unalterable, as far as could be defined, during a period of one year. It was not sufficient that a good number of these resistances had been unaltered; if it happened that a wire coil which was to be used for centuries as a standard underwent changes—and they never could know what was taking place in its interior—many complications and difficulties would ensue. Therefore, they had come to the conclusion that it would be better to keep up the old definition of resistance given at first by Dr. Werner Siemens, the definition arrived at by means of a mercury column. They had many accurate experiments with regard to the definition of those mercury columns. One of his (the speaker's) assistants, Dr. Dorn, a very able worker, had found out some new errors which had not previously come under observation. He found that when such a mercury column in a narrow tube and surrounded by a thick tube of glass, even when surrounded by ice water, became heated; if only by $\frac{1}{2}$ of a degree it was sufficient, the resistance of such a mercury column was altered and the alteration could be measured. It was at the limits of observable alteration, but it could be measured and was quite regular. It was even possible to measure the degree of conductivity of the glass tube for heat by observing these little alterations of temperature. They must, therefore, suppose that all the observations of the resistance of mercury hitherto made had been a little too high, and that it was necessary to be careful in taking note of these alterations. Then there came out a very curious thing about the influence of the capillary force on the filling of the mercury tubes with mercury. It was demonstrated by these experiments of Dr. Dorn that the mercury did not quite completely touch the glass tube if it was not filled up in a vacuum, remaining under the influence of the vacuum for rather a long time. An easier way of filling was to bring a drop of petroleum between the mercury and the glass, when the mercury came immediately into contact with the glass, and they got less resistance in such a column of mercury than with any other methods of filling. That value of resistance which was the smallest was probably the right one; every other resistance which was a little greater showed that the filling was not complete. This was also a reason for determining that the mercury column should not be defined by the length and the diameter, for nobody could measure with absolute accuracy the internal diameter of a glass tube of a square millimetre section. This rendered it necessary to arrive at the determination by weight. It came out that, as far as it was possible to make the comparison, the English standards were in so good an agreement with the German independently-made standards, that there was no reason to go further for industrial purposes; for industrial purposes the accuracy was sufficient, he supposed he might say, for centuries. For scientific purposes there would, perhaps, be necessary some alterations in the determinations; but that was a question of time, and scientific people who had a good definition of standards could themselves make the little alterations that were necessary. He thought all the European nations, and North America as well, were very near to coming to an agreement, and if there was good will on all sides, the very unpleasant state of things which would result if they had different measures in different countries would be avoided. It was the object of the German scientists in coming there, being sent by their Government, to try to bring about an agreement with England at first, and they hoped that afterwards America and France would come into agreement also.

The PRESIDENT: This report may be taken as a proof that the work of the Association is not confined to one week in the year, but that it is going on all the year round, and that this week of meeting is really only the climax. We all greatly thank Dr. von Helmholtz for his statement, and also specially thank Mr. Glazebrook for the very great pains he has taken in this matter.

SECOND REPORT ON THE DEVELOPMENT OF GRAPHIC METHODS IN MECHANICAL SCIENCE.*

[ABSTRACT.]

BY PROF. H. S. HELE-SHAW, M.INST.C.E.

Three years ago a preliminary report was presented on the above subject by the Committee, consisting of Mr. W. H. Preece (Chairman), Mr. (now Sir) Benjamin Baker, Messrs. W. Anderson and G. Kapp, Profs. J. Perry and R. H. Smith, with the present writer as Secretary, who, at the meeting in the following year, was requested by the Sectional Committee to draw up and complete the report. Owing to causes which were explained in a letter to the Committee, last year, he was unable to do this in time for the following meeting, and now begs to present the result of his work up to the present time on the subject.

The preliminary report gave a list of a number of works which avowedly dealt with graphic methods; but, at the same time, it was stated that a large number of standard works, based to a great extent on such methods, or in which such methods were frequently applied, were excluded from the list. It does not require much acquaintance with the subject to realise that there is scarcely a treatise or publication dealing with mechanical science that does not employ some kind of graphical expression as a means of exposition or calculation. How great the range is may be gathered from a consideration that graphic methods really include every way of representing numerical quantities by means of drawing, except

1. The representation of actual bodies.
2. Purely geometrical construction.

Hence we have to go back very early in the history of mechanical science to find the first graphic treatment of the subject. A study of the list of references to graphic applications in scientific literature of this country appended to this report will show that gradually, but with an ever-increasing rate, it has become the custom to employ representations of numerical results graphically, and to suggest and use the solutions of various problems by graphic methods.

These two purposes, viz.:—

1. Representation of results by means of plotted curves and autographic diagrams,
2. Solution of problems by graphical methods,

seem to suggest a satisfactory way of dealing with the subject.

At the same time no hard and fast distinction must be insisted on, because a curve, although chiefly useful for the purposes of representing the general results of an experiment or calculation, may be employed by means of interpolation or otherwise to effect a calculation.

Now it would be quite legitimate in this report to trace the development of the manner of representing results, and also of the building up of geometrical theories which are employed for purposes of graphical calculation. For the former, however, the best method of procedure is to state the results which have been achieved, as this aspect is the practical and useful one.

Inasmuch as every possible kind of numerical quantity can be plotted, it would not be possible, even if it were desirable, to give anything like a complete list of the subjects which have been or may be plotted. Further, in dealing with the instruments used as self-recording or otherwise, there must be omissions, because descriptions of many such instruments are not to be found anywhere; hence the object in dealing with this part of the report has been to give a clear statement which will convey an idea of the progress and present state of the subject. Moreover, the appended list of references obviates to a great extent detailed references to authorities and journals when dealing with the descriptive portion.

The fact is, the difficulty of ascertaining what subjects in mechanical engineering have been treated graphically in current literature, is very great. Nothing less than an examination of every page of engineering journals and scientific papers suffices for this purpose, since no intimation is usually given in the index, hence the list of references which has been added is arranged under suitable headings of the more important applications of mechanical science, wherever such applications have been treated graphically. In one column the names of the subjects are given under which the article is found in the journal—in another, the description of the graphic diagram—in another, the author's name. The arrangement of matter under each heading is in the order of the year of publication, so that anyone searching for graphical records on a certain subject will see at once what is old and what is new.

Very different, however, is the case of the graphical treatment of problems. This is a subject of very divided opinion, whereas the mere representation of results has settled down into recognised lines and methods of operation. Great as the progress has been in this direction, it will be seen that there is a wide field for discussion in the present state of the question, hence in this portion of the report an attempt has been made to present the views of different schools of thought, and to state the results achieved up to the present. At the same time the question is far too wide to be treated in the present report in a way at all justified by its importance, and it is a question for the Section to decide whether a further report dealing more fully with foreign literature and practice in graphic methods in relation to mechanical science is not desirable.

To the treatment of the two subjects thus divided there is prefixed a statement of the geometrical principles involved in the methods of graphical representation. This preliminary statement is necessary to show both the possibilities and methods of graphical

* British Association, Section G, Edinburgh, August, 1892.

Digitized by Google

records, as well as to premise the considerations in the second portion dealing with calculation.

The foregoing remarks will explain the following scheme of the report.

SCHEME OF REPORT.

I.—*Geometrical Considerations involved in (1) the Representation of Results Graphically, and in (2) Graphical Calculations.*

1. Use of one dimension of space corresponding to measurement from one fixed point in a plane, enabling one variable to be dealt with. The use of two dimensions of space corresponding to the measurement from two fixed points in a plane, enabling the position of a point to represent two variable quantities. The use of three dimensions, or of representation of three variables by the positions of a point involving the use of models or stereotomy, is excluded from consideration in treating of graphical methods.

2. Practical distinction between analytical treatment and geometry of position. The graphical calculus.

II.—*The Representation of Results.*

1. The plotting of diagrams; the use of squared paper. Growth of the method. Plotted tables. Contributions on Naval Architecture by Mr. H. H. West; and on Electrical Work, by Mr. F. G. Baily. Applications in civil and mechanical engineering.

2. Instruments for drawing known curves used with graphical methods Improvements in simple drawing instruments. Elliptographs, drawing the parabola. Harmonic curves; the involute; cycloid; spirals, &c. The gabarit. The integraph.

3. Self-recording instruments. Marking arrangements. Modes of actuating surface for receiving the record. The movement of the recording arrangement. Instruments for recording (*a*) levels, (*b*) pressure, (*c*) magnetic attraction, (*d*) velocity, (*e*) temperature, (*f*) vibrations and shocks, (*g*) results and mathematical operations, (*h*) chronographic results.

III.—*Graphical Solution of Problems.*

1. Consideration of modern methods of graphical calculation, chiefly in view of continental use and opinions concerning the application of projective geometry in graphic statics.

2. Addition of parallel segments. Sliding calculation and slide rules. Shearing force and load diagrams.

3. Addition of non-parallel segments. Summary of the applications of the principle of reciprocal figures.

4. Graphical multiplication. Culmann's method. The rectification and calculation of areas. Planimeters and integrators. Summary of the problems in engineering to which methods of graphical multiplication are applied.

IV.—*Classified List of Reference to Graphical Methods.*

List of transactions, proceedings, and periodicals from which references are taken.

Alphabetical list of subjects, under which the references are classified in order of the year of publication.

(*Here follows list of References.*)

EARTH CURRENTS.

In connection with the recent earth-current disturbances and Mr. Preece's Paper thereon at the British Association, the following new Post Office form of report will be of interest:—

Date.	Name of circuit affected (codes not to be used).	Relative geographical position of terminal offices with respect to each other.	Greenwich time (state a.m. or p.m.).		Current.		Deflection shown on instrument galvanometer when switch turned to simplex.	Circuits not affected by earth currents at the same time as the others.		Remarks.
			Commenced.	Ceased or changed direction.	Direction.	Strength in milliamperes.		Name of circuit.	Relative geograph cal position of terminal offices with respect to each other.	
			H. M.	H. M.

* The direction of the received current is positive or negative when it flows into the station, either as a copper or as a zinc current respectively from the terminal point

THE LONDON OVERHEAD WIRES ACT, 1891—COUNTY COUNCIL BYE-LAWS.

In our issue of December 11, 1891, we published a set of by-laws relating to overhead wires, which had been approved by the London County Council, but not by the Board of Trade. We print below the by-laws as finally amended and approved by the Board of Trade on July 29th.

In these by-laws—

The expression "the Act" means the London Overhead Wires Act, 1891.

The expression "wire" has the same meaning as in the Act, except that it does not include any support or attachment.

The expression "cable" means any covered or insulated wire, of which the diameter to the outside of the covering exceeds twice the diameter of the bare wire, and where more wires than one are enclosed in the same covering or insulation, includes all such wires and covering, without reference to diameter.

General.

1. The Company shall deliver to the Council and the Local Authority full particulars of the material and gauge of the wires of the Company, and the nature and position of the several supports, and the length of span between the several supports. The Company shall also deliver to the Council a plan, on a scale of not less than 25in. to the mile, showing the routes of such wires, and the position of the supports or at their option shall cause the routes of such wires and the position of the supports to be marked upon a map to be supplied for the purpose at the office of the Council.

Existing Wires.

2. In the case of wires or supports existing at the date of the approval of these by-laws the Company shall comply with the requirements of by-law 1 within six months after that date.

New Wires.

3. In the case of new wires or supports placed after the date of the approval of these by-laws, the Company shall comply with the requirements of by-law 1 within one month after the placing thereof.

4. A wire shall not be placed so as at any point to be at a less height above the ground than 20ft., or, where it crosses a street, 35ft., or at a less height above the roof of any building than 6ft., except where it is brought into any building for use in that building, or is attached to a chimney or other part of a building in accordance with these by-laws.

5. Every wire shall be supported at intervals not exceeding 115 yards, unless permission in writing be obtained from the Council and the Local Authority for a longer span.

6. Every support for a wire shall be of durable material, and properly stayed against forces due to wind pressure, change of direction of the wires, and unequal length of span; and all independent conductors and suspending wires shall be securely attached to the supports.

7. The factor of safety for all stresses arising from the weight of conductors and suspending wires shall be at least four at a temperature of 22° F. The factor of safety for all other parts of the structures shall be at least ten, taking the maximum possible wind pressure against a support acting in a horizontal direction at 30lb. per square foot. No addition need be made for a possible accumulation of snow.

8. Every support for a wire shall be marked in such manner to be approved in the case of each company by the Council as to identify the company to whom it belongs.

9. Where a support is used for the wires of more than one company, the company owning the support shall be responsible for the support and the attachment of the wires thereto.

10. No cable shall exceed one pound per lineal foot in weight; and every cable shall be carried by independent suspending wires and attached to the same by efficient slings.

Digitized by Google

11. Every iron or steel wire, and every iron or steel support or attachment, shall be efficiently protected from oxydation.

12. All poles erected on buildings as supports for wires, unless fixed through the roof, shall be carried on shoes or saddles properly protected from oxydation, and shall be efficiently stayed, so that in the event of a pole breaking it shall be impossible for it to fall into any street.

13. Every wire attached to a chimney, wall, or other part of a building, shall be efficiently supported by angle plates of iron or bronze or other device approved by the Local Authority.

14. Every wire support and attachment shall be duly and efficiently supervised and maintained by the company.

15. No wire support or attachment shall be in such a condition that danger to the public using the streets may be apprehended therefrom; and the Company to whom any wire support or attachment being in such condition belongs, shall be guilty of an offence against these by-laws.

16. No wire support or attachment shall remain erected after it has ceased to be in use, unless the Company intend within a reasonable time to take it again into use, and give notice of such intention to the Council and the Local Authority.

17. On reasonable notice being given by the Council or the Local Authority to the Company, access at all reasonable times for the purpose of inspection of the Company's wires, supports, and attachments shall be given or secured by the Company to the inspectors of the Council and the Local Authority.

Penalties.

18. Any company or person failing to comply with any of these by-laws, or of the provisions of the London Overhead Wires Act, 1891, or delivering any particulars which to their or his knowledge are incorrect, shall be guilty of an offence against these by-laws, and shall be liable to a penalty not exceeding £5, and to a further penalty not exceeding 40s. for each day during which such offence is continued after conviction thereof.

[N.B.—The Act (see section 18) does not extend to any wire placed by any person for his private use over land belonging to him or in his occupation, which does not extend over any street thereof or attachment, and is so constructed and placed that neither the wire nor any support, thereto would be liable to fall into any public street.]

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 12, 1892.

The Toronto Meeting of the Association of Edison Illuminating Companies.—The eighth annual meeting of the Association of Edison Illuminating Companies met in Toronto on Tuesday of this week. About 50 members were present to discuss questions which are considered of the greatest importance to those who are operating Edison central stations. Since the consolidation of the Edison and Thomson-Houston Companies was accomplished it has been thought by some that the Edison Association would of necessity take steps to consolidate with the National Electric Light Association. Such, however, does not seem to be the intention of the Association, and, considering the action taken at the recent meeting, it is more likely that the membership will be extended so as to include those who are operating other than Edison stations. This has always been the tendency of the managers of the electric light companies in this country; that is to say, to meet together and consider subjects which are of the greatest importance from an economical and financial point of view, the proceedings of the convention, however, being always withheld from publication. The convention held this week is no exception to the rule, only those who were members being given an opportunity of listening to the discussions. Mr. C. A. Coffin was present at one of the sessions, and took part in the discussion of certain questions regarding the business policy of operating companies. The most important Paper presented was that of Mr. J. H. Vail on "The Application of New Apparatus and High Economy Engines in Central Stations to Secure Greater Commercial Efficiency and Economy of Coal." Mr. Vail took up the discussion of the introduction of triple expansion engines into central stations, to be operated by direct connection to the armatures of multipolar generators, as well as the question of using improved methods for obtaining a high economy in the consumption of coal. One of the interesting features of the convention was the presentation by Mr. William Lloyd Garrison, of Boston, of his pioneer experience in incandescent electric lighting at Brockton, Mass., in one of the earliest Edison Central stations, and the one in which the first underground three-wire system was operated on a commercial scale.

CORRESPONDENCE.

THE DIMENSIONS OF PHYSICAL QUANTITIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As I expected, "W. M. M." has again failed to answer the simple question I put to him.

In transforming the equation $t\,[T] = l\,[L]$ into another form I was careful to give the meaning of every one of the new symbols. It is therefore remarkable that "W. M. M." should put forward an argument which is entirely invalidated by the fact that a and b are variables. It is evidently necessary "to define my position" in the very simplest terms. I therefore submit that $[L] = 2$ is an equation, that it is perfectly valid if $[L]$ is abstract, but is false by Fourier's rule and by the definition of the symbol $[L]$. Hence $[L]$ is not abstract.

I am at present travelling, and am not seeing *The Electrician* regularly. This accounts for the fact that this letter is tardy; and as similar difficulties will beset my correspondence for some weeks to come I must ask you to allow what follows to close this series of letters as far as I am concerned.

The difficulties of "W. M. M." are due to the fact that he fails to see that the dimensional notation is expressly intended to meet them. Maxwell explains this as clearly as possible in the passage I quoted, but "W. M. M.," with strange perversity, twists his words into a sense diametrically opposed to what he himself admits is their more obvious—and, as I have no hesitation in saying, is their true—meaning.

By separating the symbols which represent the abstract multipliers and the concrete units respectively we are free to perform arithmetical operations with the former and to attach any meaning we please to symbols which are written as algebraical products or divisors of the latter. We are not bound to regard $\left[\frac{L}{T}\right]$ as a length divided by a time.

It is a symbol for a concrete velocity which conveniently expresses the relations of the unit velocity to the concrete units of length and time. The view of "W. M. M." is like that of a student who might insist that $\frac{du}{dt}$ is always $= \frac{u}{t}$ because (as he would say) the d's cancel in the numerator and denominator. I am quite aware that my view is not free from difficulties, but they are fast disappearing by investigations such as that of Mr. Williams. They certainly are not such as to drive me to the absurd conclusion that such an equation as $[L] = 2$ is valid.—Yours, &c., ARTHUR W. RÜCKER.

ELECTRICAL UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May we who actually handle electrical units every day of our lives contribute a word to this discussion? We have for so many years treated the total induction as the important quantity in magnetics, and altogether ignored the illusory formula $\mathsf{B} = \mathsf{H} + 4\pi\mathsf{I}$, that we cannot help rejoicing to see how one by one the shining lights of the professorial world are quietly omitting all reference to $4\pi\mathsf{I}$, and speaking of ampere-turns and total induction as cause and effect.

Those whose business it was to measure these things every day very soon felt the need of a name less cumbrous and dogmatic than "one line of force," and following the precedent set by those who coined the word *farad* we proposed to call the unit of total induction a *thom*. And why not? The sole reason against this convenient name has disappeared with the translation of Sir William Thomson to another sphere, and some of us who remember him with affection would like to be reminded of him every time we measure an induction.

But now Dr. Lodge proposes to solidify 100,000,000 thoms into one magnificent unit, and call it a weber; for much the same reason as led the B. A. to define the farad. No doubt the fact that *if* you thread one weber into a circuit in one second you can get an E.M.F. of one volt has an attractive simplicity about it; so has that other fact, that if you charge a farad up to one volt it holds a coulomb. Only nobody really does either of these things—partly because they do not want to, but chiefly because they cannot. We generally have

Digitized by Google

to do the best we can with a great deal less than a weber, and if the induction cannot be put into the circuit in the twinkling of an eye it is not worth using.

Consider a few examples, taken at random, of such inductions as are continually dealt with in a works test-room :—

	Thoms.	Webers.
Total induction threading coil of our standard of induction	1273	·00001273
Coil of a gravity ammeter	900	·000009
A ship's telegraph needle	9000	·00009
A generator magnet	8000	·00008
A generator armature	25000	·00025
A 12-kilowatt armature	$3·7 \times 10^6$	·037
A 120-kilowatt „	26×10^6	·26

Is it not obvious that a weber is absurdly large? Do not compel us to use negative powers of 10, we would far rather muddle along with the old 10^8. It is true that the thom is a very small unit—so is the second ; but *million thoms* is quite as easily written as *microwebers*, and more easily understood.

The desire to name units after Gauss and Weber is very natural as a compliment to the German nation ; but the use of those names cannot add a jot or tittle to the honour in which they are held by the whole scientific world. The name gauss should however be allowed to drop, solely for euphonious reasons—gausses is unbearable ; but the unit magnetic force might be christened a *weber* if our suggested *thom* is adopted.

We have another reason for desiring to name the induction unit ourselves ; in adopting the *thom* the B. A. and the Professors would be paying a delicate compliment to him for whose convenience all units are devised—the despised "practician."—Yours, &c.,

SYDNEY EVERSHED.
ERNEST B. VIGNOLES.

Woodfield Works, W., Aug. 23, 1892.

THE COST OF THE ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Could some of your readers give from actual experience, under different circumstances and in different districts, particulars of what electric light supplied from central stations has cost them, mentioning cost of installation, rent of meter, supply bill, and any other expenses, and the size of the house. I, for one, should be grateful for this information, and I think it would be generally useful.—Yours faithfully,

August 18, 1892. ROBT. LEHFELDT.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Administration of the Belgian State Railways in Brussels invites tenders (to be opened at 11:45 a.m. on the 31st inst.) for the installation of the necessary machinery and apparatus for the electric lighting of the station at Ath.

——— The Direction Général des Postes et des Télégraphes invite tenders for the supply of 100,000 kilogrammes of high conductivity copper wire and 6,000 couplings for this wire. Forms of tender must be obtained from 103, Rue de Grenelles, Paris, before Monday next, and the tenders will be opened at 11 a.m. on the 8th prox.

——— Tenders for lighting the city of Belem do Gram-Parà, United States of Brazil, by gas or electricity, will be received up to November 30th next at the office of the Secretary to the Municipal Council. Particulars can be had on application to the Brazilian Legation, 55, Curzon-street, Mayfair, W. (where a plan of the said city may be seen), or to the Brazilian Consul-General, 6, Great Winchester-street, London, E.C.

POOLE AND WHITE (LIMITED).—A petition for the winding up of this Company was down for hearing before the Vacation Judge on Wednesday, but we have authority for announcing that the case was withdrawn before being reached.

THOMAS BARRACLOUGH AND CO. (LIMITED).—Claims against this Company (in voluntary liquidation) must reach the liquidator, Mr. Alfred Tongue, 44, Brown-street, Manchester, by September 24th.

BANKRUPTCY PROCEEDINGS.—Mr. Rankin Kennedy, electrical engineer, Carntyne Electrical Works, Glasgow, was examined in bankruptcy on Monday in the County Buildings, Glasgow, before Sheriff Birnie. The state of affairs showed the net assets to amount to £2,055. 2s. 5d., and the liabilities to £714. 14s. 9d. The bankrupt considered that his assets should realise sufficient to pay 20s. in the £1 to his creditors and leave a surplus. The cause of his difficulties was insufficiency of capital to carry on his contracts, and certain creditors having lodged arrestments and otherwise taken proceedings. The examination was closed.

ATELIERS HOSTER DE ST. NICHOLAS (LIMITED). — The first meetings of creditors and of contributories of this Company (in liquidation) will be held at 33, Carey-street, W.C., on Wednesday next, the 31st inst., at 11 and 11.30 respectively.

PARTNERSHIP DISSOLVED.—The partnership between Messrs Grist and Turner, carrying on business at 33, Gracechurch-street, E.C., as electrical engineers and contractors, has been dissolved. Debts will be paid by Mr. C. J. Grist.

MESSRS. G. E. BELLIS AND CO.—Mr. Willoughby Warden, 60, Robertson-street, Glasgow, has been appointed representative of the above firm for Scotland and Belfast.

THE CRYSTAL PALACE EXHIBITION.—We have received from the Harburg India Rubber Company a souvenir of the recent Exhibition at the Crystal Palace. This souvenir takes the form of a medal worked in vulcanite, set in a neat case, and accompanied by some friendly remarks from Mr. F. Winter, who represents the Harburg Company in this country. It appears that the Company have been sending out samples of their specialities to electrical firms who have obtained prizes at the Exhibition ; in each case the samples have taken the form of the medal referred to, the execution of which reflects much credit upon the Company. About 800 persons are engaged in the manufacture of vulcanite articles for electrical engineers, &c.; and the firm claim that they have amongst their customers the leading electrical houses, in addition to the chief European Governments. The medal certainly forms an admirable advertisement for Mr. Winter's firm.

MR. LEOLINE A. EDWARDS.—This gentleman has been appointed sole London representative of Messrs. T. L. Hemming and Co. (Limited).

MESSRS. ANDERSON AND MUNRO.—This firm have several electric light installations on hand, amongst them being one for Sir Archibald Edmonstoun, Bart., at Duntreath Castle, and one for Mr. George Neilson at Cressbasket. The former is for 200 8 c.p. and 100 16 c.p. lamps, the current being supplied by a Goolden dynamo, and the latter for 175 16 c.p. lamps, fed by a Siemens dynamo. Turbines are the prime movers in each instance.

MESSRS. ERNEST SCOTT AND MOUNTAIN (LIMITED).—This firm have secured the contract for lighting the Co-operative Wholesale Society's premises at Newcastle-on-Tyne ; the installation consisting of three 25 H.P. gas engines and three Tyne compound-wound dynamos. Other contracts recently secured by the firm are lighting the Ashington Colliery and Messrs. Chadwick Brothers' mill in Russia, in addition to an electric pumping plant for the Newton Colliery Company.

TELEGRAPH MESSENGERS.—The late Postmaster-General during his term of office gave particular attention to the appearance and bearing of the telegraph messengers. Arrangements have been made that the lads attached to the principal offices shall be drilled ; and the late Postmaster-General acknowledges the assistance he has received from the commanding officers of several Volunteer regiments in allowing the use of their drill halls, and to the Master of the Charterhouse for the use of the picturesque grounds of that Institution, where, on the 18th instant, some 300 of these messenger boys, under the command of Major J. P. Macgregor of the Post Office Volunteers, were inspected by Sir A. Blackwood, Secretary to the Post Office. Sir Arthur congratulated the lads upon their appearance, and indicated that since the commencement of the drilling, greater attention and care had been paid to their uniforms and to their general appearance.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

August 4, 1892.

14,064. W. ALDRED. Sheffield. A continuous direct electric current machine and motor.

14,089. C. C. LESENBERG and J. VON DER POPPENBURG. London. Improvements in dry batteries.

14,096. G. H. CHURCH. London. Improvements in automatic electric arc lamps.

August 5, 1892.

14,160. G. S. GRIMSTON. London. Electric apparatus for working the elevating and training gear of guns and the lifts for their ammunition.

Digitized by Google

14,180. J. L. DOBELL. London. Improvements in or connected with electric batteries.

14,181. C. P. SHREWSBURY and J. L. DOBELL. London. Improvements in or connected with electric batteries.

14,189, H. H. LAKE. London. An improved method of and apparatus for distributing alternating electric currents. (W. Stanley, jun., and J. F. Kelly, United States.)

14,193. A. FRANKE. London. Improvements in or relating to electrically-controlled valves.

August 6, 1892.

14,199. A. A. DAY. London. A new and improved form of electric testing instrument.

14,206. J. L. DOBELL. London. Improvements in or connected with electric batteries.

14,229 H. SKONE. Manchester. Improvements in incandescent electric lamp holders.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

12,602. ARON. Measuring electric currents.

12,831. RUSSELL. Curative electric belts, &c.

13,961. BENNETT. Electrical parcel exchange system.

14,217. SACCO AND GIACOMINI. Telegraphic apparatus.

14,817. HEYS (Brown). Electric tram-cars.

15,768. HALL. Distributing electricity.

16,090. PITT. Telegraph posts.

16,091. MASSEY. Electric circuits for lighting.

17,160. LAKE. (Soc. dite Electriciteits Maatschappij Système de Khotinsky.) Electric accumulators.

17,231. SIEMENS BROS. AND CO. AND OTHERS. Winding for drum armatures of dynamos, &c.

1892.

1,497. SHIELS. Couplings for electric wires.

11,403. GOOLDEN AND ATKINSON. Electric generators and motors.

11,424. DYMOND (Strowger.) Telephone, &c., exchanges.

11,692. PURDON AND OTHERS. Electric locomotives.

11,698. MEYER. Insulators for electric wires.

COMPANIES' MEETINGS & REPORTS.

Telephone Company of Ireland (Limited).

The half-yearly general meeting of the shareholders of the Telephone Company of Ireland was held on Thursday at the Commercial Buildings, Dublin. The Chairman of the Company, Alderman V. B. Dillon, presided.

The CHAIRMAN moved the adoption of the report (which appeared in *The Electrician* of the 5th inst.) and accounts. He said they had on their books between 400 and 500 shareholders, and it was gratifying to find that the report was so satisfactory that practically the attendance of shareholders was nil. It was satisfactory, although the Company had been obliged, owing to the large expenditure upon the capital account, to postpone payment, for the present, of any dividend. The Company had constructed out of their revenue account a trunk line connecting Dublin and Belfast. They had absorbed a considerable revenue which they had made during the year, and while the Company had in cash sufficient funds to pay the dividend, they had thought it more for the advantage of the shareholders to postpone paying it for the present. He was bound to congratulate the shareholders upon the progress which the Company had made since they last met. The number of wires on December 31, 1890, was 1,473, and at the present moment it was nearly 1,600, being an increase of over 100 wires, while they had now 27 orders in hand for wires in course of construction. The Company had now exchanges in Dublin, Cork and Limerick, and they were opening exchanges in Dundalk, Drogheda and Balbriggan, towns in the district which had been connected with the Company by trunk wire; and so soon as the Government carried out their proposals of connecting other cities such as Waterford, Kilkenny, Galway and other large towns in the West and South of Ireland, the Company trusted to open exchanges in these places, and to give them the facilities of inter-communication, not only with towns in Ireland, but, so soon as the development of the system foreshadowed by the Post Office takes place, with towns in England and Scotland; and ultimately telephonic communication with France and the Continent. The shareholders would, he thought, be interested to know what the Government had proposed to do in connection with telephones. They propose to connect every important town in Great Britain and Ireland with every other town by means of trunk lines. They propose to connect England and Ireland with the cable for telephonic purposes as the cable between London and Paris. They propose to allow call houses, and he hoped to see exchanges established in all sub-post offices. So that after a short time they looked forward to having a telephone wherever a telegraph office exists. They would now allow telegrams to be sent by telephone. Hitherto everybody using the telephone had to go to the Post Office to deliver a telegram, but now, after a few weeks, he trusted that users of telephones would be able to telephone their messages to the Post Office, and to have them written down without any charge being made by the Post Office authorities and transmitted. Although these changes were very important they were only some of those which were to be proposed in that way; and if the Government would endeavour to work that telephonic system with the same enterprise that they had worked the telegraph system since the introduction of cheap telegrams, after a short time it would revolutionise completely the mode of communication in these countries, and they would find that people, instead of sending telegrams, would adopt the telephone almost universally. He trusted that when the Government carried out their proposals they would make the charges so reasonable, particularly in this country, where the volume of business was not large, that the system would be adopted at once. With these observations, which he hoped might be interesting to the shareholders, he begged to move the adoption of the report and statement of accounts.

Mr. G. COCKBURN seconded the motion, which was adopted.

The CHAIRMAN moved, and Mr. COCKBURN seconded, that Mr. Arthur Dudgeon be elected a Director of the Company, which was carried.

Mr. John M. Keane having been re-elected auditor to the Company, the meeting concluded.

Birmingham Central Tramways Company (Limited).

The eleventh ordinary general meeting of shareholders was held on Wednesday at the Queen's Hotel, Birmingham, under the presidency of Mr. Joseph Ebbsmith.

The report and statement of accounts having been taken as read,

The CHAIRMAN then said that from a public point of view the working of the Company during the past year had been eminently satisfactory. They had carried a million and a-half more passengers—namely, 25,718,000, against 24,381,000 last year. When, however, they took the report from the point of view which more immediately concerned them as shareholders, that of the net profit which had been made, the results were found to be that, although their traffic receipts had risen from £143,000 to £152,000, their working profits had sunk from £43,000 to £37,000. It had been his custom somewhat minutely, year by year, to criticise the various items of receipt and expenditure, and for that purpose he had been supplied with an analytical statement from the Managing Director, a copy of which had been supplied to each shareholder as he entered the room. Mr. Wain had been continually pressing the Directors to purchase thirty heavier steam engines than those now in use; but the Directors shrank from the expenditure of such a large sum until they had a better understanding with the local authority with respect to the repair of the roads, and they thought it would be better to overwork their engines for a time rather than spend a sum of money which might possibly be found to be sunk altogether. It would not be fitting that they should pass lightly over what was in his opinion the most serious factor in the report—namely, the results of the working of the electric department. They would recollect that in this matter they were on the horns of a dilemma. They were committed to the completion of the Bristol-road route under certain contracts by cable; and they were aware that exactly as the cable was a gold mine on suitable lines, so it was a sink for money where the traffic was not sufficient, and where the lines were not suitable. At the same time they had heard of the wonders that were to be accomplished by electricity, and the most sanguine results were foreshadowed. The policy which the Board adopted was laid before the shareholders and approved by them; and now, looking at the accounts of the electric department, he was glad to say that the matter stood far more hopefully than it impressed him at the first blush. It was necessary for them to consider what were the leakages before they could say what would be the permanent loss. There were two causes of leakage which ought to be, and he trusted would be, stopped. After alluding to the charges made by the Corporation for repairs of roads, the Chairman said that there was another matter which came more immediately within their own ken, and that was the cost of maintenance of batteries upon the Bristol Road route, and which had been simply monstrous. It had amounted, roughly speaking, to 3d. per mile run in the sense of what he might term engine-power. This, too, was a matter which was pressed upon them by their Managing Director, the necessity of providing additional batteries to maintain the traffic upon that route. But this was too startling a matter to be dealt with hastily. They recollected their experience with the cable. When the cable route was opened one of the most able manufacturers supplied them with ropes, and the first lasted them six weeks, with the result that instead of the profit they expected they saw nothing but disastrous loss before them. What they did was this—they went to the various rope-makers and said to them, "We do not care of what or how you make the rope, but we want a rope that will last, and on what terms will you make a contract to supply us for three years with ropes?" This proved satisfactory, and they had now adopted the same principle with regard to the batteries under terms which meant a penny per mile instead of threepence. The Chairman went on to explain the course of business which he proposed to adopt, stating that he should submit a series of resolutions dealing with the separate recommendations of the report, and proposed first of all the payment of a dividend of 5 per cent. on the preference shares.

Mr. M. J. SMITH seconded the motion, and it was carried.

The CHAIRMAN then moved that the balance of £13,921 should be carried forward pending the decision of the Public Works Committee, and the decision of a subsequent meeting as to the reduction of capital, but afterwards withdrew the resolution, and moved that a committee of shareholders be appointed to assist the Directors on the question of dealing with the Corporation, and to confer with them on the question of reduction of capital.

Mr. NEALE having seconded this latter resolution,

Mr. LIVESEY proposed, as an amendment, to omit the words relating to the reduction of capital, as they would never get a better meeting than that to discuss the subject.

The amendment was seconded, and after some discussion it was carried, and the committee were then appointed.

Digitized by Google

A letter from the Chairman to the solicitors was then read, in which he expressed a desire to resign his position as Chairman.

A motion for the re election of the retiring Directors was defeated on a vote; but the Chairman demanded a poll, which resulted in the motion being carried.

The retiring auditors were re-elected; and the meeting, which had at times been rather stormy, terminated.

That portion of the Managing Director's report relating to the electric department was as follows:—"I regret that my own idea as to the traffic upon this line has not been justified by the result. You will remember that my estimate of the traffic was an average taking the year through of £250 per week; but the failure to reach this figure arises from causes with which you are well acquainted. There is no doubt that if we had had the means at our disposal to have conveyed the traffic my estimate would have been fully justified. One set of the new batteries has been delivered. Had we been able to maintain the service originally contemplated, the difference in traffic would have been £2,700, which would have converted the deficit into a profit of £1,000. The undue strain put upon the rolling stock, owing to the lines having been so constructed by the Corporation that they were too wide for the cars—*i.e.*, that they were out of gauge to the extent of as much as 1⅛in., resulting in the constant breakage of axles and wheels, and the consequent effect upon the working parts, and the enormous consequent strain upon the batteries, which were practically trying to grind a new groove in the metals, has naturally increased the maintenance charges to a very high figure. Again, the charge for permanent way is monstrous. It is absolutely impossible that ordinary repairs to a line which has only been constructed two years could have in the past twelve months cost the sum of £1,352. That this is so is shown by the fact that on the small portion of line belonging to us beyond the city boundary on this route we have spent practically nothing during that time. The electric expenses in fuel will show a reduction this year. The new boiler will be able to do the bulk of the work, and, owing to the price of fuel generally being reduced, we have been able to make a contract more advantageous to the Company. After making many inquiries we have negotiated an arrangement with a company under which they guarantee, after the first cost of batteries is paid, to keep them in repair and renew them when required for one penny per car mile run. The recent reduction in the electric service (which has, as the daily returns show, worked for the past few months with scarcely a hitch) has been due to the diminution of the number of batteries available for working, owing to others being worn out; and during that time the desire of the Board not to incur indefinite expenses in batteries, pending the investigation then in progress. A suggestion has been made that the electric and cable cars should be canopied. The Company would have no objection if the Board of Trade and local authorities would agree to it, although it would add considerably to the weight, and, therefore, to the cost of haulage; but the local authorities have hitherto declined to allow canopies to be placed upon the cable cars."

Hong Kong Electric Company (Limited).

The third annual ordinary meeting of this Company was held on June 11 at Hong Kong; Mr. H. L. Dalrymple presiding.

The CHAIRMAN said he did not know that he could usefully supplement the information conveyed by the manager's report attached to the accounts, which gave a concise statement of the progress made in the Company's business during the past twelve months. He regretted that the branch of incandescent lighting had not been more extended, but he thought the cause was not far to seek, and they must continue to hope that when the Colony returned to its normal state of prosperity, the hopes entertained when this Company was formed would be realised and enable the Directors to make some tangible return to the shareholders. The working of the Company for the twelve months showed an advance in the right direction, and in another year's time they would see themselves in a still better position. He must, however, point out to, and urge on, their numerous friends that on their increased support and appreciation of the manifest advantages of the electric light the success of the Company largely depended. Their plant was capable of supplying a very large addition to the amount of incandescent light at present in operation, so that the increased consumption would materially augment the revenue at a minimum extra outlay. He moved the adoption of the report and accounts.

The motion having been seconded and carried,

Messrs. J. J. Bell-Irving and J. Kramer were elected Directors in the place of Messrs. Keswick and Poesneckern (resigned), and the Hon. C. P. Chater and Mr. T. E. Davies were re-elected Directors.

City of London Electric Lighting Company (Limited).

The following report, for the period ended June 30th, to be presented to the shareholders at the second annual general meeting of the Company, to be held at Winchester House, E.C., on Thursday, September 1st, at 2:30 p.m., has been issued:—

The Directors state that they have constantly pressed forward the necessary work, and the progress made is satisfactory. All the Provisional Orders and contracts are now in the possession of the Company, and the former have received the Royal assent. The Directors have secured on favourable terms the freehold of the Bankside Central Station, and have entered into an "agreement for a lease" of 90 years for the other central station at Wool Quay. Suitable buildings have been erected for all plant now running. Additional buildings for the machinery on order are in progress, the work for which is being carried on by night and day. Sites for several transformer stations have also been acquired, and the necessary work of construction and equipment is far advanced.

Contracts for the full equipment of plant for the generating stations have been entered into under such conditions and specifications as will ensure all material and work being of the highest class and efficiency. There is already installed machinery of a capacity of 700 public arc lamps, and 23,000 8-c.p. glow lamps, including reserve. Additional machinery of a capacity of 56,000 8 c.p. glow lamps is being constructed; part of this is expected to be running by the end of October, and the remainder in the early part of 1893.

The arrangements for duly executing street work within the limited time allowed by the contracts formed the subject of serious consideration by the Board. With the object of avoiding the inconvenience to the public inseparable from frequent opening of the same streets, it was decided to lay, at one operation, "ways" sufficient for immediate requirements, together with a number of spare tubes to meet all probable developments of the Company's business. By recent legislation, electrical supply companies are authorised, subject to certain consents, to lease for telephonic purposes any spare tubes they may have.

In reference to public lighting, the report states that 184 arc street lamps were in use on June 30th, and that the greater number of lamps contracted for will be in operation by about the middle of September. The final date for completion specified in the contracts is the 5th November next.

The demand for private lighting continues to be exceedingly good. On June 30th, signed applications had been received for 32,028 lamps, chiefly from the limited area in which the current was then available. Of this number 11,860 were connected up.

The Directors have endeavoured to make their capital outlay earn revenue at the earliest possible moment, having regard to the proper execution of the work and the provision of adequate reserve power. The result is that a considerable income is already accruing. Public and private lamps installed at June 30th were estimated to be earning at the rate of £14,600 per annum, a figure which is daily increasing. From calculations based on the lamps already connected to the Company's mains, it appears that the consumption of current per lamp installed in City offices, shops, &c., will be much greater than was anticipated. There is every indication that the position of the Company is exceptionally favourable.

Messrs. W. H. Pannell and Co. retire, and, being eligible, offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

COMPOUND MOTOR COMPANY (LIMITED).—This Company was registered on August 18th, with a capital of £200, in 1s. shares, to carry on the business of engineers, merchants, railway and tramway contractors, locomotive engine builders, &c.

JOHN H. WILSON AND CO. (LIMITED).—This Company was registered on August 19th, with a capital of £20,000, divided into 1,500 £6 per Cent. Preference and 500 ordinary shares of £10 each. The objects are to acquire and take over as a going concern the business carried on at Liverpool and elsewhere by F. Bradley, and to carry on business as iron-founders, engineers, and manufacturers of cranes, winches, derricks, boilers, travellers, pumps, hoists, gears, tackle, castings, and other machinery and apparatus.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to August 5th, was filed on the 17th. The Company was registered on August 19, 1874, with a capital of £400,000, divided into 20,000 "A" and 20,000 "B" shares of £10 each. The capital was increased to £600,000, by special resolution passed November 20, 1888, by the addition of 20,000 new £10 shares. At the time of making up, all the shares were taken up, the full amount called, and all calls (£600,000) paid.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to August 2, 1892, was filed on the 8th following. The Company was registered on October 26, 1883, with a capital of £1,000,000, divided into 150,000 "A" and 50,000 "B" shares of £5 each. At the time of making up 89,261 £3 paid "A," 17,139 fully-paid "A", and 23,564 fully-paid "B" shares were taken up. 10s. per share has been called on the 89,261 £3 paid "A" shares, resulting in the payment of £44,630. 10s. The following sums have been considered as paid, viz.:—£223,152. 10s on the 89,261 £3 paid "A" shares, £85,695 on the 17,139 fully-paid "A" shares, and £117,820 on the 23,564 fully-paid "B" shares, making a total of £471,298 considered as paid.

UNITED RIVER PLATE TELEPHONE COMPANY (LIMITED.)—The annual return of this Company, made up to August 9th, was filed on the 15th. The Company was registered on December 17, 1886, with a capital of £500,000, in £5 shares. At the time of making up 58,000 shares were taken up, of which 16,000 were issued as fully paid. Upon the remaining 42,000 the full amounts have been called, and all calls (£210,000) paid.

CALLS DUE.—*Aug. 31st:* ISLINGTON AND GENERAL ELECTRIC SUPPLY (LIMITED), £1 per share. *Sept. 1st:* ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LIMITED), 10s. per share on 20,500 Perpetual £10 per Cent. Preference. *Sept. 5th:* JOHANNESBURG LIGHTING COMPANY (LIMITED), 25 per cent. (final call) on £7 per Cent. Mortgage Debenture Bonds.

CITY NOTES, &c.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—In issuing the first annual report and balance-sheet of this Company, it is notified that a much fuller balance-sheet, made up to December 31st next, in the form prescribed by the Board of Trade, will be circulated by the Directors early in 1893. The first annual report will be found in our current issue.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended Aug. 21st were £724, as against £728 for the corresponding period of last year, being a decrease of £4. The total receipts for half-year amount to £6,148, against £5,680 in the corresponding period of 1891, being an increase of £468.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Stock Exchange Committee have ordered the further issue of £56,477 Four and a-Half Debenture Stock to be quoted in the official list.

NEW TELEPHONE COMPANY (LIMITED).—Application has been made to the Stock Exchange to appoint a settling day in, and to grant a quotation to, 48,000 ordinary shares of £10 each in this Company.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Aug. 19, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,603.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated receipts of this Company for the fortnight ended August 15, 1892, were £1,982, compared with £1,630 for 1891, showing an increase of £352.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 746.—Vol. XXIX. FRIDAY, SEPTEMBER 2, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6*

NOTES.

One of the merits of the Physical Society of London, in the opinion of some of its members, has been the informality and conversational character of its meetings. The communications, though entitled "Papers," as is customary in scientific societies, have often been short discourses, sometimes without the assistance of any notes. Under these circumstances it has rested with the authors to take what steps they pleased about the publication of their contributions. Some of these have appeared in the columns of the technical journals, and others have never been heard of again. In our Notes will be found some resolutions which, while they impose certain restrictions, are not likely to lead to undue ceremony or vexatious stringency.

It is the very lack of such regulations or the inability of the committee to enforce them that detracts so much from the usefulness of the sectional meetings of the British Association, and thus an *olla podrida* of optics and dynamics leads to the state of things described by Prof. Ayrton in his letter to us this week. Not only has the Physical Society drawn up these excellent rules, but it has made definite arrangements for the publication of every Paper in full or in abstract, and we cannot doubt that the usefulness of the Society will be thus materially increased.

Slotted conduits in connection with mechanical propulsion on railways were well known long before Mr. Holroyd Smith designed his Blackpool line, and the idea of covering the slot by a movable iron strip was in use nearly half a century before Mr. Brain employed it. Fifty years ago considerable attention was being paid to pneumatic or atmospheric railways; the notion of one or two powerful stationary engines, and the absence of machinery on the trains were, no doubt, well appreciated. In 1843 a line about 1¾ miles in length was practically worked near Dublin, between Kingstown and Dalkey. Several very ingenious inventions by Murdoch and Medhurst were tried for keeping the slot air-tight. A hydraulic valve and a rope valve were used, but no great success was met until a line about five miles long was built between Croydon and Epsom by Clegg and Samuda. The conduit was 15in. in diameter, and air compressing engines of 300 H.P. were used. The cover strip did not lift clear of the slot as in the Brain system, described in another column, but consisted of a number of eight inch lengths, riveted to a steel band and to a leather strip hinged to one side of the slot. A mixture of beeswax and tallow was used to seal the joint, and the second car carried a charcoal heater to complete this operation. The leakage was said to be only one or two horse-power per mile, and a speed of over sixty miles an hour was attained. This mode of protecting a slotted conduit promises to be more useful in its application to electric traction than in its first appearance in connection with atmospheric railways.

The success which appears to have met the attempts of Captain De Khotinsky in the manufacture of glow lamps for high voltages raises once again the hope that the limits which have been reached by other makers are not so impassable as is generally supposed. Ten years ago it was said that electric lighting could barely pay at 100 volts, but that if lamps could be made which would run on circuits of 200 or 300 volts, economical supply would be assured. We cannot hope to alter the usual 100-volt standard for some time; but 200-volt lamps may find their way into use on three-wire systems, or where transformers are specially wound to suit them. Captain De Khotinsky's guarantee of his lamps is a bold departure from the common practice, but one which will, in all probability, be followed when competition becomes keen.

The apparent consequence of these high-pressure lamps, if we may use the term to imply lamps of high resistance for a given candle power, is the possibility of producing satisfactory lamps of 4 or 5 candle power for 100 volt circuits. At present, such lamps are hardly to be recommended, especially for the purposes for which they would be most useful, viz., the lighting of passages and stairs where light is required for long periods. In order to obtain a longer life for these small lamps it has been a common custom hitherto to place 102 volt lamps on 100 volt circuits, since these, running at a lower efficiency than usual, last about as long as an ordinary lamp.

The active part which the Post Office has taken in the establishment of telephonic communication, on both a large and a small scale, has been considered by many who have watched it to have been carried on for the purpose of experimenting with a system which might at no distant period or long notice be thrust upon that department. Whether such an extension of its duties is likely or no, the communication

Digitized by Google

which is being established between coastguard stations and the other telephonic work on which the Post Office is already engaged is sufficient to warrant the issue of a carefully prepared circular from the office of the Engineer in-Chief for the instruction of the officers of the department. This circular, which, by permission, we are able to reproduce in another column, will be studied with interest by many of our readers who are concerned with the use or erection of private lines, and a very valuable feature of it is the full quantitative information given in the examples. In many respects the instructions set forth in this circular are a model of clearness, notably the figuring of the resistances of each section of the line on the diagrams, as enjoined in rule 15.

In the discussion on the proposal for a National Physical Laboratory, which we print in another column, it appeared that one of the topics that has been seriously investigated at the Berlin Reichsanstalt, is the production of a set of screw gauges suitable for fine mechanism, thus doing for the optical and instrument industries what WHITWORTH did for heavy engineering. The auxiliary establishment at Weimar, where 30,000 thermometers a year are sent to be standardised and certificated, was, it appears, carried out at the expense of the GRAND DUKE OF WEIMAR for the benefit of the neighbouring glass-working industries. Were it not that the British Association screw thread has, thanks to the London Chamber of Commerce, rendered any further action unnecessary, a department for screw gauges would be doubtless equipped at the expense of His Grace the DUKE OF BIRMINGHAM for the benefit of the neighbouring screw-making industries.

In a communication to the *Electrical Engineer* of New York Prof. CARHART states that the reason for the suppression of the one square millimetre cross-section, which has hitherto appeared in the specification of the mercury unit of resistance, was the discrepancy between the standard kilogramme and the cubic decimetre of water at 4° C. We called attention to the elaborate re-determination of the weight of a cubic inch of water by Mr. CHANEY in *The Electrician*, Vol. XXV., p. 633. A good deal of information on this subject is to be found in Mr. LATIMER CLARK'S valuable Dictionary of Metric Measures. He there points out that the litre weighs only 998·93 grammes, instead of 1,000, owing to the displacement of air, and that the kilogramme and therefore the litre is supposed to be heavier than the cubic decimetre of water in vacuo by about 120 milligrams, or 1·85 grains, owing to errors in the original determination. This error corresponds to a difference of $\frac{1}{2500}$ in the lineal measurement. Freedom from air was also neglected at this period. Thus the charming simplicity of the metric system, so dear to many minds, is spoiled; and instead of specifying the one square millimetre, the unit is described as 14·4521 grammes of mercury in the form of a column of uniform cross section, 106·3cm. in length at 0° C.

While a vast amount of work has been expended on the investigation of the temporary and reversible magnetisation exhibited by electromagnets, the permanent steel bar of the lecture-room and the red varnished horseshoe of the optician have continued to spread their lines of force unostentatiously and with an inflexible persistence, but have attracted the attention of few philosophers since the days of GILBERT. It is our duty, therefore, to present to our readers any further information that we can find on this subject. In yesterday's *Daily Telegraph* we found a leading article upon some experiments performed on various animals by treating them to the strains of the fiddle, the flute and the piccolo. In the case of deer, zebras, wild asses, and "even such notoriously unemotional creatures as the tapir and ostrich," this last instrument we are told "exercised upon them the sort of influence that is brought to bear upon a group of steel filings by the repellant pole of a powerful horse-shoe magnet. It dispersed them in all directions." This kind of magnet, though unfamiliar to most of our readers, seems to be quite in accordance and compatible with the peculiar kind of electric fluid about which our daily contemporaries, and this one in particular, occasionally discourse.

One of the many characteristics which differentiate American from English engineering practice is the transatlantic fondness for huge fly-wheels and enormous belts. In many instances we have in our ignorance been puzzled to discover a *raison d'être* for this custom. Perhaps the following paragraph from our engineering contemporary *Power*, which is but a sample of similar ones appearing almost weekly in the American technical papers, gives the clue; in the United States a fly-wheel is, as its name denotes, apparently intended to "fly":—

"Still another fly-wheel accident has wrecked the electric light station at Fostoria, Ohio, and killed the engineer. The engine, freed in some manner from the control of its governor, raced until its fly-wheel burst, killing Paul Hyder, the engineer, who had run to the throttle to shut down. The fly-wheel was 16ft. in diameter, and the largest fragment was only 4ft. in length, and was found in a loft, where it had struck the rafters and fallen back upon the joist. The fly-wheel of an engine in the temporary power house on the World's Fair grounds in Chicago flew to pieces a few weeks ago, but fortunately without fatal results."

Hove.—The laying of the underground electric light mains has commenced.

Kelvinside.—A meeting of the feuars in the Kelvinside district was held last week to protest against the erection of electric light works in that neighbourhood.

Personal.—We understand that Mr. Joseph A. Jeckell, who has been connected with the cable department of the London Electric Supply Corporation for the last four years, has been appointed electrician to the International Okonite Company.

Bradford.—The Gas and Electricity Supply Committee of the Corporation are making arrangements for the extension of the electricity works, as the demand for current is steadily growing. About seventeen miles of cable have now been laid down.

Exeter.—The process of changing the system of electric lighting from overhead wires to that of underground mains has been proceeding for the past seven weeks, and is expected to be completed in three weeks. The work is being done under contract by the Fowler-Waring Company.

Errata.—On page 447 of our last issue, in the article on "The British Association Conference on Electrical Standards," line 26 from bottom read, "cross-section of such a column," instead of "cross-section of a lens column." On page 448 read "ice" for "&c.," "Kreichgauer" for "Kreschgauer," and

Digitized by Google

"manganin" for "magnesium." On page 466 the name of Prof. von Helmholtz's assistant should have been "Kreichgauer," and not "Dorn."

Specific Resistance of Peroxide of Lead.—In the course of some investigations carried out for the purpose of proving that, contrary to Streintz, electrolytically prepared lead peroxide *did* act as a metallic conductor, Mr. John Shields also approximately determined its specific resistance :—

Sp. resist. lead peroxide, chemically prepared ..... $5{\cdot}59 \times 10^9$ C.-G.-S.
Sp. resist. „ „ electrolytically „ ..... $6{\cdot}78 \times 10^9$ C.-G.-S.

No alteration was observed in these values on heating the peroxide up to 115°C.

Dundee.—The Finance Committee of the Dundee Gas Commissioners on Monday fixed the price of the electric light at 5d. per unit, being 1d. less than authorised by the Electric Lighting Order. The Secretary for Scotland has approved of the proposed borrowing for electric lighting purposes, the sinking fund being fixed to extend over 60 years. The works are expected to be completed by November.

The Chicago Exhibition.—The Exhibition buildings are to be dedicated on October 21st instead of the 12th. October 21st is the exact anniversary of Columbus's landing, allowance being made for the correction in the calendar made by Pope Gregory. ——The Electric Launch and Navigation Company of New York has been awarded the contract for running electric boats on the interior waterways at Jackson Park. It will pay the Exhibition 33⅓ per cent. of the gross receipts.

The West End Street Railway (Boston).—This Company now controls about 260 miles of track. During the past nine months the electric cars have run just on 5½ million miles, and their net earnings have amounted to $810,024, or 15 cents per car mile run. During the same period the horse cars have run 7¼ million miles, and have earned $367,036 net, or only 5 cents per mile run. In 1888 the operating expenses of the Company were 78·29 per cent. of the total receipts; in 1891 they were reduced to 74·48 per cent. Every year the earnings have been sufficient to pay the interest on the funded debt, 8 per cent. on the preferred stock, and 10 per cent. on all outstanding common stock.

Electrical Nomenclature.—One of the main points in coining names is harmony, says Mr. L. Gutmann in the *Electrical Engineer*, of New York, alluding to the advisability of introducing short words in place of such terms as "continuous-current generator," &c. The name "commutator" would, he thinks, have been the best for a continuous-current machine if it had not been adopted long ago for the mechanical device used as a portion of a continuous-current machine. The next best name seems to him to be "continuator," and similarly, "pulsator," so that we should have for the alternating-current dynamo, "alternator;" for the pulsatory current dynamo, "pulsator;" and for the continuous-current dynamo, "continuator."

Lightning Fatalities.—On Tuesday, 23rd ult., a sad fatality occurred at Stodmarsh, near Sandwich. Two men were standing at a doorway watching a storm when one of them was struck dead by lightning and the other badly injured. At Wickham, near Wingham, on the following day, a market gardener was talking to a labourer at the door of the latter, during the prevalence of a storm, and both were struck by lightning, the former fatally. During a violent thunderstorm on Wednesday last a shepherd was killed by lightning while tending his flock at Eglingham Quarry, a few miles from Alnwick. Lightning also struck Swansfield-house, Alnwick, the residence of the Duke of Northumberland's agent, demolishing a chimney and doing other damage.

Action at a Distance.—A correspondent of the *Standard* describes some *séances* given by a Madame Eusapia, in Italy. A long time ago this lady received an injury to the head, which has partially destroyed her sense of touch. Anent this, Prof. Lomoroso writes that he sees nothing inadmissible in the supposition that with hysterical or hypnotic subjects the excitation of certain centres should produce transmission of power. He admits that sensitiveness has left the body, but claims to have localised it in a zone not far removed from the body. His opinion is supported by that of Colonel de Rochas d'Aiglun, Administrator of the École Polytechnique, who, struck by the absence of feeling in catalytic patients, was led to investigate the subject. He says that, although the body of a hypnotic patient is directly insensible to pain, yet if the air be pinched at a few inches from the body the pinch will be felt. Sometimes the sensitive zone is several yards away. Here is a grand field for experiment, and a vast opening for new developments of "action at a distance."

The Physical Society of London.—The Council of this society has passed the following resolutions :—

1. That in future the rule that no Paper shall be read at a meeting of the Society until it has been reported on by a member of Council, shall be strictly observed. 2. That, when possible, proofs of the Papers to be read shall be printed and distributed to those persons who are likely to add to the interest of the discussions on them. 3. That special invitations shall be sent for any meeting to such persons, whether members of the Society or not. 4. That the secretaries shall note on each Paper the date on which it is received. 5. That the secretaries shall endeavour to obtain as many Physical Papers as possible in good time, so that they can be classified and Papers on similar or connected subjects can be read at each meeting.

Every Paper communicated to the Society is now published either in full or in abstract. If published in full it is published in the first instance in the "Philosophical Magazine," as communicated by the Society, and 100 copies of the Paper are sent to the author. Papers which have thus appeared in the "Philosophical Magazine" are afterwards reprinted in the "Proceedings" of the Society. Papers which the Council decide not to publish in full are published in abstract in the "Proceedings" of the Society.

The Magnetic Properties of Aluminum-Iron.—In a recent number of the Cornell *Crank* Mr. C. Eickemeyer details the results of some investigations as to the magnetic properties of aluminum-iron. A preliminary test showed that the magnetic properties of aluminum-iron differed so little from those of ordinary cast iron that it was necessary, in order to determine any difference whatever, to reduce the castings to standard size. The test was made by balancing the aluminum-iron with a test piece of Norway iron, the magnetic characteristic of which was known. The Al-Fe was not compared directly with the standard Norway iron, but to reach a greater exactness in determining the difference between ordinary cast iron and the samples of Al-Fe, first, a sample of ordinarily good cast iron was tested by comparing it with the standard Norway iron. The Al-Fe was then compared with this sample of ordinary cast iron and the difference between them determined. This method largely eliminated the influence of remanent magnetism in the comparative tests. In the comparisons made, the piece containing the smaller percentage of aluminum proved to be superior to the one containing the larger percentage of aluminum. From which it may be concluded that the addition of aluminum has no very marked influence upon the magnetic conductivity of cast iron, only slightly decreasing it.

A New Source of Revenue for Electric Traction Companies.—In October, 1891, the Capital Street Railway Company, of Little Rock, Ark., says the *Electrical World*, closed a contract with the Thomson-Houston Electric Company to equip the system with electricity. Some twenty 30 H.P. motor cars and six "trailers" are now in operation, and the line, with the following exception, offers no peculiarity. The power house is situated on the Arkansas River at a point midway between Little Rock and Big Rock, and overlooking the country for miles in either direction, and the Ozark Mountains on the north and west, it gives the most beautiful view that can be obtained in the city, which resulted in the designer providing for a summer theatre to be placed upon the roof. To those not familiar with the location of this plant, the idea of a theatre on the top of a power station may seem absurd, says our contemporary, but when it is remembered that the roof of this building has an area of over six-tenths of an acre, and is located about one hundred feet above the river, entirely removed from the noise of the machinery, and giving one of the most beautiful views that can be obtained in the Ozark Mountains, the idea may not seem so peculiar. Again, as the power station is located on the main line of the street railway, the theatre produces a source of revenue to the road that makes it quite an important factor.

The Electrification of Steam Jets.—In December, 1890, Mr. Shelford Bidwell exhibited some striking experiments before the Physical Society on the electrification of steam jets. The image of a jet was thrown upon the screen, and was seen to be practically transparent. Upon the jet being electrified, however, the image immediately became dark and dense. Mr. Shelford Bidwell stated that he had examined the absorption spectrum of the jet, and that when unelectrified there was very little action, but that electrification caused a total disappearance of the violet. He concluded that the observed effects were due to electrification increasing the size of the water particles contained in the steam jet. In a Paper read before the Royal Society in March last Mr. John Aitken traverses this conclusion, and enumerates a large number of facts tending to show that the dense form of condensation is not due to an increase in the size of the drops, but to an increase in their number accompanied by a diminution in their size. Lord Rayleigh's experiment showing that it is only very feeble electrifications which cause water drops to coalesce, while strong electrifications have the diametrically opposite effect, is also cited in support of the author's contention. Mr. Aitken remarks that it has been generally stated that the effect of the electrification is sudden and marked. If, however, the discharging point is extremely fine, or if we assist the discharge by means of a flame, then we may begin with electricity of a very low potential, and the increase in the density of the jet may be made to begin by almost imperceptible degrees.

The San Salvatore Funicular Electric Railway.—There is an electrical funicular line running up the peak of San Salvatore, the summit of which is some 2,000ft. above Lugano. The line consists of a single track one mile long, and is on the Abt system. The average gradient on the lower half is 28 per cent., and on the upper portion 50 per cent. One 48-passenger car ascends, while another descends, the two cars meeting at the middle of the line, where the passengers change over. The generating station is at Maroggia, some 840ft. below a reservoir, which is fed through a pipe at the rate of 55 gallons a second, from a stream 3 miles off. Only a portion of the available power is at present utilised. A 250 H.P. horizontal Girard turbine is coupled direct to two 100 H.P. 2,000 volt lighting alternators, supplying current to Lugano; and a 125 H.P. turbine drives a 60 H.P. 1,800 volt generator. The field-magnet coils of this generator are automatically short-circuited when the current on the line increases beyond a certain amount. The line connecting Maroggia with San Salvatore hauling-house is 4½ miles long, and consists of 5mm. copper wire carried on Johnson and Phillips' oil insulators. The conductors are protected from lightning by a barbed-iron wire, which runs above them, and is connected to earth. At the San Salvatore works, the hauling-drum is driven by a 50 H.P. compound-wound motor running at 700 revolutions. The motor is belted to countershafting, from which the drum is driven by bevil wheels. A steam-engine is held in reserve. The installation was carried out by the Oerlikon Works.

An Invitation to Exhibit.—Advices from England seem to indicate an apathy in that quarter in regard to the World's Fair that is difficult for us (*Electricity*, of New York) to understand. The manufacturers of agricultural implements have about decided to make no exhibit. This we can readily understand, for the United States is so far in advance of all other countries in this branch of manufacture that for Great Britain to exhibit in this class would be but to advertise her own incompetency. The steam-engine makers have also decided to hold aloof, and we are not so much surprised at this, for it is our opinion that we lead the world in this direction also. And now *The Electrician* editorially remarks, on July 15th, "but it is not improbable that many dynamo makers agree with the steam-engine makers as to the policy of not exhibiting at all." At first blush we were inclined to think *The Electrician*, which has never been favourable to the World's Fair, was expressing its wish rather than the facts, but on looking more closely into the matter we find that the prospect of a good Electrical exhibit from Great Britain is at present exceedingly slim. . . . *The Electrician* has all along been howling about the tariff as an invitation to keep away, but the nonsense of this has been clearly pointed out from time to time by Mr. Dredge, Mr. Preece and others. It is possible that things may take a more favourable turn ere long, and Mr. Preece is bending all his energies to bring this about; but if the turn does not come, Great Britain will advertise her inability to compete with other civilised countries in terms so unmistakable that it will be difficult for her to explain the matter away.

The Indian Telegraph System.—During the year 1890-91 the line mileage of the Indian telegraph system increased by 5 per cent., the total now being 37,000 miles. The total number of telegraph offices now open is 3,103, as against 2,935 in 1889-90. Private telegrams increased 8 per cent. during 1890-91, and now stand at nearly three millions; receipts, however, only increased by a trifle over 1 per cent. The Administration continues to purchase old railway rails, and to make telegraph poles out of them, and in the twelve months under consideration purchased 19,000 for that purpose. Four cables were laid across the River Irrawaddy, near Ava, three across the Hooghley, two across the Rudda, and one across the Bassein (Burmah). In Burmah and Assam some 200 miles of line were constructed for strategical purposes, mostly under great difficulties. The rebellion in Manipur in March, 1891, naturally resulted in the complete destruction of the line running through that state, which was, however, soon restored. During the twelve months under consideration the average duration of the line interruptions was 23 hours, as against 21 hours for the previous year, and the number was 1,473 as against 1,389; an increase due chiefly to inundations in Upper Burmah. Some 48 interruptions were caused by lightning, and 110 by birds and other animals. Interruptions due to "malevolence" are on the increase. At Moulmein rats caused a two days' interruption by their consumption of the gutta-percha of a cable; and at the same place two interruptions, lasting respectively 21 and 26 hours, were brought about by white ants getting mixed up with the lightning protectors. In Upper Burmah wild elephants were responsible for three interruptions, lasting in all 201 hours.

A Pacific Cable Survey.—The following facts elicited by the latest U.S. survey of the ocean bottom between San Francisco and Honolulu are given by the *Western Electrician*:—The "Thetis," says our Chicago contemporary, left San Francisco on April 18th last to take soundings over the proposed route from California to the Sandwich Islands, the first section of a proposed cable route to Japan. Six months ago the "Albatross" made a similar survey, but the results attained at that time were not considered of a nature very favourable to the project. The "Albatross" surveyed a route running from a point on Monterey Bay direct to Honolulu. Her soundings showed that the bottom of the sea was very irregular over the greater part of the route surveyed. The depths were considerable, and a great many lofty coral reefs were discovered along the track. The "Thetis" started from Point Conception, 220 miles south of San Francisco. This place is considered by electricians to be favourable for a deep-sea cable landing. The "Thetis" took a course nearly due south-west, and by way of the Great Circle. At the beginning soundings were made every two miles until a depth of 900 fathoms was registered. Five miles out from Point Conception bottom was found at 87 fathoms, and at 13 miles 281 fathoms were registered. From that point onwards the depth increased gradually to 3,000 fathoms. That was the average for many miles. When the bottom was level soundings were taken every 10 miles, and where it was irregular, undulating, or where reefs were discovered, soundings were taken at short intervals down to two in a mile. The greatest depth sounded on the route was 3,228 fathoms, at a point about 300 miles from Hilo, on the island of Hawaii, where it is proposed to land the cable. The water shoaled to 1,000 fathoms 35 miles from Hilo, and shoaled gradually from that on to the landing place, near which the depth is 20 fathoms. For the route surveyed by the "Thetis" the cable to the Sandwich Islands would be 2,060 miles in length. The route surveyed by the "Albatross" was about 50 miles longer. The approximate distances of each route are:—British Columbia to Japan, 3,600 miles; San Francisco to Japan, 5,900 miles; British Columbia to Australia, 6,750 miles.

ELECTROMAGNETIC THEORY.—XXXV.

BY OLIVER HEAVISIDE.

(*Continued from page 356.*)

§ 160. Linear vector functions of a vector play a very important part in vector-algebra and analysis, just as simple equations do in common algebra. Thus, in the theory of elasticity the strain vector is a linear function of the direction vector, and the stress vector is another linear function of the direction vector. In electromagnetism the electric displacement is a linear function of the electric force, and so is the conduction current-density; whilst the magnetic induction is a linear function of the magnetic force, when its range is small enough. There are, therefore, at least five examples of linear vector functions to be considered in electromagnetism. In other sciences too the linear function often turns up, and frequently in pure geometry, when treated algebraically. Finite rotations may be treated by the method, and in the algebra of surfaces of the second order the linear connection between two vectors is prominent. It would be inexcusable not to give some account of linear operators in this chapter on vector-analysis and its application to electromagnetism. The subject, however, is such a large one that it is only possible to deal with its more elementary parts in a somewhat brief manner—not, however, so brief as to be useless.

The simplest kind of linear connection is that of Ohm's law in isotropic conductors. We have $C = kE$, where E is the intensity of electric force and C the current-density, whilst k is a constant, the conductivity. No specification of direction is here made. But when vectorised, we have the equation $\mathbf{C} = k\mathbf{E}$ instead, k being as before. We now assert that **E** and **C** are parallel, whilst their tensors are in a constant ratio, for all directions in space.

Suppose, however, we alter the conductivity of the body in a certain direction, say that of **i** (*e.g.*, by means of compression parallel to **i**), making it k_1, whilst its conductivity is k_2 in all directions transverse to **i**. We now have $C_1 = k_1E_1$, and $\mathbf{C}_1 = k_1\mathbf{E}_1$, when the electric force is parallel to **i**. But if it be transverse to **i**, then we have $\mathbf{C} = k_2\mathbf{E}$. There is, in both cases, parallelism of **E** and **C**, but the ratio of the tensors differs in the two cases. What, then, is the current when **E** is neither parallel nor transverse to **i**? The answer is to be obtained by decomposing **E** into two components, one parallel to **i**, the other transverse; then reckoning the currents to match by the above, and finally combining them by addition. Thus

$$\mathbf{C} = \mathbf{i}.k_1E_1 + \mathbf{j}.k_2E_2 + \mathbf{k}.k_2E_3, \quad . \quad . \quad . \quad (1)$$

where E_1, E_2, E_3 are the **i**, **j**, **k** scalar components of **E**. We have here made use of the linear principle. It is that the sum of the currents due to any two electric forces is the current due to the sum of the electric forces. This principle (suitably expressed) applies in all cases of linear connection between two vectors, and is the ultimate source of the simplicity of treatment that arises.

More generally, let the conductivity be different in the three co-perpendicular directions of **i**, **j**, **k**, being k_1, k_2, k_3 respectively. Then we have

$$\mathbf{C} = k\mathbf{E} = \mathbf{i}.k_1E_1 + \mathbf{j}.k_2E_2 + \mathbf{k}.k_3E_3. \quad . \quad . \quad . \quad (2)$$

The current is now coincident with the electric force in three directions only, namely, along the principal axes of conductivity. When **E** has any other direction than that of a principal axis, we have no longer parallelism of **C** and **E**, and their relation is expressed by equation (2). It is the general type of all linear relations of the symmetrical kind when referred to the principal axes, if we remove the restriction which obtains in the electrical example that the k's must be all positive. Given, then, that $\mathbf{C} = k\mathbf{E}$, with the understanding that **C** is a symmetrical linear function of **E**, so that k must represent the linear operator connecting them (the conductivity operator in the above example) the full answer to the question, What is the **C** corresponding to a given $\mathbf{E}^2$ is obtainable in the above manner, viz., by first finding the axes of parallelism of **E** and **C** and the values of the principal k's, and next, by adding together the three **C**'s belonging to the three component **E**'s parallel to the axes.

The inverse question, given **E** find **C**, is similarly answerable. For if $\mathbf{C} = \rho\mathbf{E}$, where ρ is the operator inverse to k (or the resistivity operator in the case of conduction-current), we know that $k_1\rho_1 = 1$, if ρ_1 is the constant resistivity parallel to **i**, and similarly $k_2\rho_2 = 1$ and $k_3\rho_3 = 1$ for the **j** and **k** axes, so that in full,

$$\mathbf{E} = \rho\mathbf{C} = \mathbf{i}.\rho_1C_1 + \mathbf{j}.\rho_2C_2 + \mathbf{k}.\rho_3C_3, \quad . \quad . \quad . \quad (3)$$

where C_1, C_2, C_3 are the scalar components of current.

Precisely similar remarks apply to the permittivity operator c in $\mathbf{D} = c\mathbf{E}$ connecting the displacement **D** with the electric force **E**, and to the inductivity operator μ in $\mathbf{B} = \mu\mathbf{H}$, connecting the induction **B** with the magnetic force **H**, when the connection is a linear one. It is not without importance to constantly bear in mind the above process of passing from **E** to **C** through k, and the process of inverting k to ρ, because when treated in a general manner, with reference to any axes, the relations become much more complicated, whilst their intrinsic and resultant meaning is identically the same.

§ 161. Next let us obtain some geometrical illustrations of the previous. The transition from **E** to **C** is like that from a sphere to an ellipsoid. If a solid be uniformly subjected to what is termed a homogeneous strain, any initially spherical portion of it becomes an ellipsoid. If this be done without rotation, the state is such that all lines parallel to a certain axis, say that of **i**, in the unstrained solid are lengthened or shortened in a certain ratio in passing to the strained state, without change of direction. The same is true as regards lines parallel to two other axes, say **j** and **k**, perpendicular to each other and to the first axis. The ratio of lengthening or shortening is generally different in the three directions of preservation of parallelism.

The equation of the ellipsoidal surface itself is

$$1 = \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2}, \quad . \quad . \quad . \quad . \quad . \quad (4)$$

when referred to the centre and the principal axes. Here a, b, c, are the lengths of the principal semi-axes, whilst x, y, z, are the scalar components of **r**, the radius vector from the centre to any point of the surface. It may be written

$$1 = \left(\mathbf{i}\frac{x}{a} + \mathbf{j}\frac{y}{b} + \mathbf{k}\frac{z}{c}\right)^2 = \mathbf{N}^2 \text{ say}, \quad . \quad . \quad (5)$$

from which we see that when **r** belongs to the ellipsoid, **N** is a unit vector, the vector radius of a certain sphere from which the ellipsoid **r** may be obtained by homogeneous strain, the three ratios of elongation being a, b, c (that is, the co-ordinate x/a in the sphere become x in the ellipsoid, and so on).

Now, if we square (3) and divide by $\mathbf{E}^2$, we may write it

$$1 = \frac{C_1^2}{(k_1E)^2} + \frac{C_2^2}{(k_2E)^2} + \frac{C_3^2}{(k_3E)^2}, \quad . \quad . \quad . \quad . \quad (6)$$

where the C's are the components of **C**, and E is the tensor of **E**. Now suppose E is constant, and let **E** take all directions in succession. Its extremity will range over a spherical surface. Now the end of the corresponding **C** or $k\mathbf{E}$ will range over an ellipsoidal surface. For we may take k_1E, k_2E, k_3E in (6) to be a, b, c in (4); when C_1, C_2, C_3 will simultaneously be x, y, z. The semi-axes of this current-ellipsoid are the principal currents in the directions of parallelism of electric force and current.

Similarly to (6), we have, by squaring (2),

$$1 = \frac{E_1^2}{(\rho_1C)^2} + \frac{E_2^2}{(\rho_2C)^2} + \frac{E_3^2}{(\rho_3C)^2}, \quad . \quad . \quad . \quad . \quad (7)$$

from which we see that when C is constant, so that the vector **C** ranges over a spherical surface, the corresponding **E** simultaneously ranges over the surface of an ellipsoid whose principal semi-axes are the principal E's.

There are other ways of illustration than the above. Thus we may see from the form of the right number of (4) that it is the scalar product of **r** and another vector **s**, thus

$$\mathbf{rs} = 1, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

where **r** and **s** are given by

$$\mathbf{r} = \mathbf{i}x + \mathbf{j}y + \mathbf{k}z, \quad . \quad . \quad . \quad . \quad . \quad (9)$$

$$\mathbf{s} = \mathbf{i}\frac{x}{a^2} + \mathbf{j}\frac{y}{b^2} + \mathbf{k}\frac{z}{c^2} \quad . \quad . \quad . \quad . \quad . \quad (10)$$

Digitized by Google

Here we see that $\mathbf{s}$ is a linear function of $\mathbf{r}$, and such that if $\mathbf{N}=\phi\mathbf{r}$, then $\mathbf{s}=\phi\mathbf{N}=\phi\phi\mathbf{r}=\phi^2\mathbf{r}$. See equation (5). The interpretation of the new vector $\mathbf{s}$ is easily to be found. It is the reciprocal of the vector perpendicular from the centre upon the tangent plane to the ellipsoid at the extremity of $\mathbf{r}$. For if $\mathbf{p}$ be this perpendicular, the projection of $\mathbf{r}$ upon $\mathbf{p}$ is evidently $\mathbf{p}$ itself, because the three vectors $\mathbf{r}$, $\mathbf{p}$, and the line in the tangent plane joining their extremities form a right-angled triangle whose longest side is $\mathbf{r}$. Therefore

$$\mathbf{rp}=\mathbf{p}^2, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

or, dividing by $\mathbf{p}^2$,

$$\mathbf{rp}^{-1}=1, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

comparing which with (8), which is true for all $\mathbf{r}$'s of the ellipsoid, we see that $\mathbf{s}=\mathbf{p}^{-1}$, as stated.

Now we have

$$\frac{\mathbf{EC}}{\mathbf{EC}}=1\,\frac{\mathrm{E}_1^2}{\rho_1\mathbf{EC}}+\frac{\mathrm{E}_2^2}{\rho_2\mathbf{EC}}+\frac{\mathrm{E}_3^2}{\rho_3\mathbf{EC}}, \quad . \quad . \quad . \quad (13)$$

from which we see that if we construct the ellipsoid whose principal semi-axes are $(\rho_1\mathbf{EC})^{\frac{1}{2}}$, and so on, the radius vector will be $\mathbf{E}$ and the corresponding reciprocal perpendicular will be $\mathbf{C}/\mathbf{EC}$. Here $\mathbf{EC}$ is understood to be constant.

Similarly, we have

$$1=\frac{\mathrm{C}_1^2}{k_1\mathbf{EC}}+\frac{\mathrm{C}_2^2}{k_2\mathbf{EC}}+\frac{\mathrm{C}^2{}_3}{k_3\mathbf{EC}}, \quad . \quad . \quad . \quad . \quad (14)$$

so that in the ellipsoid with principal semi-axes $(k_1\mathbf{EC})^{\frac{1}{2}}$, &c., the radius vector is $\mathbf{C}$ and the reciprocal perpendicular is $\mathbf{E}/\mathbf{EC}$. In both these methods of representation neither $\mathbf{E}$ nor $\mathbf{C}$ has constant tensor, but their product, the activity, is constant.

In the case (6), where it is E that is considered constant, the reciprocal of the perpendicular on the tangent plane to the ellipsoid of $\mathbf{C}$ is

$$\frac{\mathrm{iC}_1}{(k_1\mathrm{E})^2}+\ldots=\frac{\mathrm{i}\rho_1\mathrm{E}_1}{\mathrm{E}^2}+\ldots=\frac{\rho\mathbf{E}}{\mathrm{E}^2}. \quad . \quad . \quad . \quad . \quad (15)$$

This is also an ellipsoid. For $k\mathbf{E}$ is an ellipsoid, and $\rho\mathbf{E}$ only differs in the principal constants being the reciprocals of those in the former case.

Similarly, in the case (7), where C is constant, the reciprocal perpendicular is

$$\frac{\mathrm{iE}_1}{(\rho_1\mathrm{C})^2}+\ldots=\frac{\mathrm{i}k_1\mathrm{C}_1}{\mathrm{C}^2}+\ldots=\frac{k\mathbf{C}}{\mathrm{C}^2}, \quad . \quad . \quad . \quad (16)$$

and again the extremity of $k\mathbf{C}$ ranges over an ellipsoidal surface.

Thus the sphere of $\mathbf{E}$ with constant tensor is associated with an ellipsoid $k\mathbf{E}$, whose reciprocal perpendicular is $\rho\mathbf{E}/\mathrm{E}^2$ or $k^{-1}\mathbf{E}/\mathrm{E}^2$, another ellipsoid. It follows that the reciprocal perpendicular of the latter gives us the former ellipsoid again, or the same with radius vectors altered in a fixed ratio.

This reciprocal relation of two ellipsoids through their inverse perpendiculars is an example of Maccullagh's extraordinary theorem of reciprocal surfaces. It may be stated thus. Let

$$\mathbf{r}_1\mathbf{s}_1=1, \quad \text{and} \quad \mathbf{r}_2\mathbf{s}_2=1, \quad . \quad . \quad . \quad . \quad (17)$$

be the equations of two surfaces referred to the same origin, $\mathbf{r}_1$ and $\mathbf{r}_2$ being the radius vectors, and $\mathbf{s}_1$, $\mathbf{s}_2$ the reciprocals of the vector perpendiculars from the origin on their tangent planes. If, then, we choose $\mathbf{r}_2$ to be $\mathbf{s}_1$, we shall simultaneously make $\mathbf{s}_2$ be $\mathbf{r}_1$. That is, starting with the surface $\mathbf{r}_1$, construct the surface whose radius vector $\mathbf{r}_2$ is $\mathbf{s}_1$, the reciprocal perpendicular of the $\mathbf{r}_1$ surface. Then the reciprocal perpendicular $\mathbf{s}_2$ of the second surface ($\mathbf{s}_1$ or $\mathbf{r}_2$) will be the radius vector $\mathbf{r}_1$ of the first surface.

This admits of simple vectorial proof. For if $\mathbf{r}_1\mathbf{s}_1=1$ be the equation of a surface according to the above notation, we obtain, by differentiation,

$$\mathbf{r}_1 d\mathbf{s}_1+\mathbf{s}_1 d\mathbf{r}_1=0, \quad . \quad . \quad . \quad . \quad , \quad (18)$$

if $d\mathbf{r}_1$ and $d\mathbf{s}_1$ are simultaneous variations of $\mathbf{r}_1$ and $\mathbf{s}_1$. But $d\mathbf{r}_1$ is in the tangent plane to $\mathbf{r}_1$, and therefore at right angles to $\mathbf{s}_1$, so that $\mathbf{s}_1 d\mathbf{r}_1=0$. This leaves $\mathbf{r}_1 d\mathbf{s}_1=0$ also. But $d\mathbf{s}_1$ or $d\mathbf{r}_2$ equivalently is in the tangent plane of the surface whose vector radius is $\mathbf{s}_1$, or $\mathbf{r}_2$; therefore $\mathbf{r}_1$ is parallel to the perpendicular on the same, or parallel to $\mathbf{s}_2$, say, $\mathbf{r}_1=x\mathbf{s}_2$, from which $\mathbf{r}_1\mathbf{s}_1=x\mathbf{s}_1\mathbf{s}_2$ or $x\mathbf{r}_2\mathbf{s}_2$. But $\mathbf{r}_1\mathbf{s}_1=1$ and $\mathbf{r}_2\mathbf{s}_2=1$, so $x=1$, and $\mathbf{r}_1=\mathbf{s}_2$, which completes the connections.

In terms of the perpendiculars, let p_1 and p_2 be their lengths and r_1, r_2 the corresponding radius vectors, then

$$r_1 : r_2 = p_1 : p_2, \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

and $\mathbf{r}_1$ is parallel to $\mathbf{p}_2$, and $\mathbf{r}_2$ to $\mathbf{p}_1$.

§ 162. Leaving now the geometrical illustrations connected with the ellipsoid, consider the symmetrical linear operator by itself. If $\mathbf{D}=c\mathbf{E}$, where c is the linear operator, we know by the above exactly how it operates through the principal c's. We can, however, write c in such a manner that it shall state explicitly its meaning. Thus, if c_1, c_2, c_3 be the principal c's belonging to the axes of $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$, we have

$$c\mathbf{E}=\mathbf{i}.c_1\mathrm{E}_1+\mathbf{j}.c_2\mathrm{E}_2+\mathbf{k}.c_3\mathrm{E}_3, \quad . \quad . \quad . \quad (20)$$

by § 160. Now put the E's in terms of $\mathbf{E}$, producing

$$c\mathbf{E}=\mathbf{i}.c_1\mathbf{i}\mathbf{E}+\mathbf{j}.c_2\mathbf{j}\mathbf{E}+\mathbf{k}.c_3\mathbf{k}\mathbf{E}. \quad . \quad . \quad . \quad (21)$$

In this form, the operand may be separated from the operator, thus

$$c\mathbf{E}=(\mathbf{i}.c_1\mathbf{i}+\mathbf{j}.c_2\mathbf{j}+\mathbf{k}.c_3\mathbf{k})\mathbf{E}, \quad . \quad . \quad . \quad (22)$$

so that the expression for c itself is

$$c=\mathbf{i}.c_1\mathbf{i}+\mathbf{j}.c_2\mathbf{j}+\mathbf{k}.c_3\mathbf{k}. \quad . \quad . \quad . \quad . \quad (23)$$

In this form, with a vector to operate upon implied, the nature of c is fully exhibited. But the operand need not follow the operator. If it precedes it the result is just the same. Thus by (23),

$$\mathbf{E}c=\mathbf{E}\mathbf{i}.c_1\mathbf{i}+\mathbf{E}\mathbf{j}.c_2\mathbf{j}+\mathbf{E}\mathbf{k}.c_3\mathbf{k}$$
$$=c_1\mathrm{E}_1.\mathbf{i}+c_2\mathrm{E}_2.\mathbf{j}+c_3\mathrm{E}_3.\mathbf{k}=c\mathbf{E}. \quad . \quad . \quad (24)$$

When, however, the operator is unsymmetrical, the vectors $c\mathbf{E}$ and $\mathbf{E}c$ are not identical. They are said to be conjugate to one another, so that in the symmetrical case of identity, c is also called a self-conjugate operator. The distinction between symmetrical and skew operators will appear later.

There are six vectors concerned in c, viz., $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$, and $c_1\mathbf{i}$, $c_2\mathbf{j}$, $c_3\mathbf{k}$, which call $\mathbf{I}$, $\mathbf{J}$, $\mathbf{K}$. Thus

$$c=\mathbf{i}.\mathbf{I}+\mathbf{j}.\mathbf{J}+\mathbf{k}.\mathbf{K} \quad . \quad . \quad . \quad . \quad . \quad (25)$$

is the type of a symmetrical operator referred to the principal axes. Now the general form of c referred to any axes and with the symmetrical restriction removed is obtained by turning these six vectors to any six others; thus,

$$\phi=\mathbf{a}.\mathbf{l}+\mathbf{b}.\mathbf{m}+\mathbf{c}.\mathbf{n}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (26)$$

so that

$$\phi\mathbf{E}=\mathbf{a}.\mathbf{l}\mathbf{E}+\mathbf{b}.\mathbf{m}\mathbf{E}+\mathbf{c}.\mathbf{n}\mathbf{E}, \quad . \quad . \quad . \quad . \quad . \quad (27)$$

$$\mathbf{E}\phi=\mathbf{E}\mathbf{a}.\mathbf{l}+\mathbf{E}\mathbf{b}.\mathbf{m}+\mathbf{E}\mathbf{c}.\mathbf{n}, \quad . \quad . \quad . \quad . \quad . \quad (28)$$

show the linear function and its conjugate explicitly. This is (with a changed notation, however), Prof. Gibbs's way of regarding linear operators. The arrangement of vectors in (26) he terms a dyadic, each term of two paired vectors ($\mathbf{a}.\mathbf{l}$) being a dyad. Prof. Gibbs has considerably developed the theory of dyadics.

Returning to the simpler form (25) or (22), we may note the effect of the performance of the operation symbolised by c a number of times, directly or inversely. Thus by (22) or (21), or (20), we have

$$\left.\begin{aligned} c^2\mathbf{E}&=cc\mathbf{E}=\mathbf{i}.c_1{}^2\mathrm{E}_1+\mathbf{j}.c_2{}^2\mathrm{E}_2+\mathbf{k}.c_3{}^2\mathrm{E}_3,\\ c^3\mathbf{E}&=cc^2\mathbf{E}=\mathbf{i}.c_1{}^3\mathrm{E}_1+\mathbf{j}.c_2{}^3\mathrm{E}_2+\mathbf{k}.c_3{}^3\mathrm{E}_3,\\ c^{-1}\mathbf{E}&=\mathbf{i}.\frac{\mathrm{E}_1}{c_1}+\mathbf{j}.\frac{\mathrm{E}_2}{c_2}+\mathbf{k}.\frac{\mathrm{E}_3}{c_3}, \end{aligned}\right\} \quad . \quad . \quad (29)$$

and so on. Thus c^n means the operator whose principals are the nth powers of those of the primitive c, with the same axes. We therefore get a succession of ellipsoids with similarly directed principal axes, only altering their lengths, when the initial $\mathbf{E}$ has a constant tensor. (That is, provided the principal c's are all positive. If some be negative, we have other surfaces of the second order to consider.)

We may also manipulate in the same simple manner any number of operators, a, b, c, &c., which have the same principal axes, though they may differ in other respects. Thus, using the same kind of notation,

$$\left.\begin{aligned} a\mathbf{E}&=\mathbf{i}.a_1\mathrm{E}_1+\mathbf{j}.a_2\mathrm{E}_2+\mathbf{k}.a_3\mathrm{E}_3,\\ ba\mathbf{E}&=ab\mathbf{E}=\mathbf{i}.a_1b_1\mathrm{E}_1+\mathbf{j}.a_2b_2\mathrm{E}_2+\mathbf{k}.a_3b_3\mathrm{E}_3,\\ cba\mathbf{E}&=abc\mathbf{E}=\mathbf{i}.a_1b_1c_1\mathrm{E}_1+\mathbf{j}.a_2b_2c_2\mathrm{E}_2+\mathbf{k}.a_3b_3c_3\mathrm{E}_3, \end{aligned}\right\} \quad . \quad (30)$$

Digitized by Google

and so on. That is, the successive action of any number of symmetrical operators with common principal axes is equivalent to the action of a single operator of the same kind, whose principals are the products of the similar principals of the set of operators. The resulting ellipsoids have their axes parallel throughout. Next, multiply the equation (20) by any other vector **F**, producing

$$\mathbf{F}c\mathbf{E} = c_1E_1F_1 + c_2E_2F_2 + c_3E_3F_3. \quad . \quad . \quad . \quad (31)$$

By symmetry we see that this is identically the same as **E**c**F**. We might also conclude this from the fact that c**E** and **E**c are the same vector; or, thirdly, by forming c**F**, and then multiplying it by **E**. We may therefore regard **E**c**F** as the scalar product of **E** and c**F** (or **F**c), or, as the equal scalar product of **E**c (or c**E**) and **F**. This reciprocity is the general characteristic of symmetrical operators, by which they can be distinguished from the skew operators. The electrical meaning in terms of displacement and electric force is that the component displacement in any direction **N**, due to an electric force acting in any other direction **M**, equals the component displacement along **M**, due to the same electric force along **N**.

(To be continued.)

DUBLIN CENTRAL ELECTRIC LIGHTING STATION.

In November, 1890, a special committee of the Dublin Corporation selected the tender of the Electrical Engineering Company of Ireland for the electric lighting of Dublin, but a strong minority of the Corporation were in favour of the Irish House-to-House Electricity Company, and a compromise was eventually effected, and it was decided on February 11, 1891, to give the contract to the Electrical Engineering Company of Ireland on the assurance that they would have the assistance of the Irish House-to-House Company in the execution of the contract. It is hardly necessary to remind our readers that the Electrical Engineering Company of Ireland is a branch of the Brush Electrical Engineering Company, and the Irish House-to-House Electricity Company is associated with Messrs. Hammond & Co.

The central electric lighting station which has just been erected for the Dublin Corporation is centrally situated in Fleet-street, at the rear of the old Parliament Houses. Here are erected the three sets of the two kinds of plants, viz., the Lowrie-Parker high tension alternating current system for supplying current to consumers' houses, and a continuous current Brush system for lighting the streets by means of arc lamps. For the private lighting there are three pairs of compound horizontal non-condensing engines, of 280 H.P. each, working at a pressure of 140lb. per square in. in the steam chests, and running at a speed of 85 revolutions per minute. The admission and exhaust of the steam is regulated by the well-known patent Corliss valve system. The fly-wheels, weighing nearly 10 tons each, are 14ft. in diameter, and are grooved for 12 cotton ropes running direct to the dynamos. The engines are of Irish make, being specially built by Messrs. Coates and Co., of Belfast. There are two main ranges of steam pipes and one range of exhaust piping, the latter running from the low-pressure cylinders of the engines to the feed-water heaters, which are erected at one end of the boiler house. The engine foundations are built of concrete and granite blocks from a depth of 16ft. where the solid rock was reached.

Coupled direct by 12 1½in. cotton ropes to the engines are the Lowrie-Parker alternating-current dynamos, each giving an output of 75 amperes at 2,000 volts—or, in other words, each machine is capable of supplying current to 5,600 lamps of 8 c.p. Their speed is 350 revolutions per minute. The speed at which the armature conductor is passed by the field-magnets is about 6,000ft. per minute, giving a frequency of about 83 complete periods per second. All three machines are identical. The armature conductor coils are formed of narrow copper tape, each wound in a plane upon a piece of insulating material of the same thickness as the width of the tape, and rounded at the ends. These coils are placed close together upon the cylindrical inner surface of the armature ring. The armature coils are easily removed or replaced as required, and this remark applies likewise to the magnet windings. The armature ring is divided on the horizontal line, so that the upper half is removable for inspection or repairs. The moving part of the machine consists of a solid, soft wrought-iron ring, with pole-pieces securely attached thereto, and is arranged so that the centrifugal force of the whole of the moving parts is taken by the ring.

The bearings are 20in. long; they are in halves, jointed on the horizontal centre and fitted with loose brasses of phosphor bronze, top and bottom. The bottom brass is so arranged that it can be removed without lifting the shaft.

The exciter is a series-wound machine, with drum armature running at a speed of 800 revolutions. We are not in possession of any information about the output.

At the opposite end of the room are situated the three arc lighting sets supplied by the Brush Electrical Engineering Company, comprising three vertical compound Raworth engines and three continuous-current Brush dynamos. The engines are 60 H.P., and run at a speed of 220 revolutions per minute. The low pressure cylinder is fitted with automatic relief valves. The fly-wheels are 8ft. in diameter and grooved for 8 cotton ropes, thus coupling the engines direct with the dynamos, which have an output of 10 amperes at 3,000 volts. The speed of the dynamos is 800 revolutions per minute. The armatures are of laminated iron, wound with coils in twelve recesses, the opposite coils being connected in series, the free ends being brought out through the shaft, which is hollow, to the plates of the commutator in the usual way. A travelling crane capable of lifting 10 tons is erected in the engine-room, and is used for moving and erecting the heavy portions of the machinery.

The steam-generating plant is composed of four Babcock and Wilcox water-tube boilers, each capable of evaporating 8,500lb. of water per hour at a pressure of 150lb. per square inch. The total heating surface in each boiler is 51sq. ft. They are set in two batteries of two boilers each, each battery being provided with a steam receiver having outlets for the connections to the main ranges of steam pipes. The steam and water drums are 36in. in diameter and 33ft. 7in. long, made of steel ⅜in. thick.

Close to the boilers are three Worthington Steam Pumps, each capable of supplying water to two boilers when fully loaded. Three feed-water heaters each heating a sufficient quantity of water to feed two of the boilers are provided. They are connected with the main exhaust steam pipe, and are fitted with bye-passes and stop-valves, to enable the exhaust steam from the engine to be sent through any of the feed-water heaters or past them. The exhaust pipes are carried from the heaters up the chimney to within a few feet from the top.

At the east end of the buildings are commodious offices and switch and test rooms. The switch room, in which all the electrical connections converge, is fitted with a very complete set of instruments for controlling the current and regulating its distribution between the several circuits. The three alternating current dynamos are connected by separate leads with the private lighting switchboard, so that any one of them can be run on either of the two mains. The arrangements also permit of the machines being run in parallel, and a special synchronising board is provided for this purpose.

The mains from the alternators are first brought to safety fuses in the switchboard arranged so that a fuse can be instantly replaced without stopping the dynamo; and by a system of four break switches any dynamo can be put in communication with any circuit or circuits, or the whole of the dynamos be put in parallel circuit. Besides these mains conveying the entire output of the dynamo, a small wire placed across one coil of the armature is also brought to the switch-room; this is for measuring the voltage, synchronising, and for regulating the pressure. Each coil being similar, the measure of one coil is a direct proportion of the whole, and entirely prevents any inaccuracies that would occur in measuring from a transformer. A simple current meter is also included on the switchboard to indicate to the attendant approximately the current given out by each dynamo. When the maximum safe load of any dynamo is reached, the attendant can either put in another machine parallel or put one of the circuits on some

Digitized by Google

lighter loaded dynamo, if working independently. The synchronising is affected through the one-coil circuit; for instance, if one machine shows by the indicator that the load is approaching the normal, and another plant is started, a small switch places the second machine parallel with the first machine, through one lamp only placed on the synchronising board. When the phases of the two dynamos correspond, the lamp is steady and bright, but not until then. The second machine is then instantly put in parallel with the first by the insertion of one main switch, and at once takes half the load. The regulation is also done from the single coil current, a small converter being interposed between it and the regulator to ensure the attendant from any shocks that might accrue from a fault on the circuits or dynamo. A complete set of voltmeters and ammeters is provided, the former being of the well-known Cardew type.

A hand regulator in the form of a variable resistance is placed in the exciter circuits for keeping the voltage constant between the mains. The latter, however, will not as a rule be needed, as three of the Lowrie-Hall Patent Automatic Regulators have been put in connection with the machines. The principal is that of a shunt of varying resistance on the magnet of the exciter.

Automatic regulators of the Brush-Geipel type are put in conjunction with each of the arc lighting machines, and serve to maintain a very constant current in the mains. The principle upon which they work is a shunt on the field magnet circuit of the machines, the excitation of which is modified so as always to maintain the most suitable current in the lamps.

All the instruments for both public and private lighting with the exception of the automatic regulators are fixed to large polished slate bases, supported by a strong wooden framework which forms two sides of the room. Between this frame-work and the brick wall of the building is a passage of about 3ft. wide, with a trench containing the cables running to the street and dynamos; and from these all the necessary connections to the instruments are made and can always be readily inspected.

The mains are laid underground, chiefly below the pavements, and consist of lines of cast iron culverts and boxes into which the cables are drawn. Various sizes of pipes are used from 3in. to 6in. in diameter, the Lowrie-Hall surface boxes, however, are made on the interchangeable system, and are suited to any size pipe, and are placed in the street at a distance of about 70 yards apart. By the aid of these boxes the cables can be drawn out and inspected for repairs if necessary without any further interference to the street from box to box. The pressure on the mains which will convey the electricity to the public street lamps will reach a maximum of 3,000 volts, while the current for lighting up private houses will be transmitted from the dynamo along the cables at 2,000 volts. Before it enters the house, however, it is reduced by means of Lowrie-Hall transformers to 100 volts. Schallenberger meters will be used.

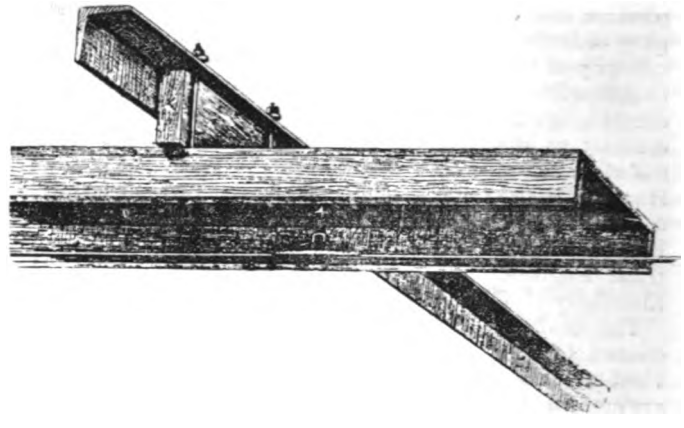
At present only the following streets will be lighted by electricity: Grafton-street, College Green, Dame-street, Parliament-street, Capel-street, Mary-street, Henry-street, Sackville-street, D'Olier-street, College-street, and Westmoreland-street. In these streets are erected 78 lamp-posts reaching to the height of about 23ft. The lamps are of the Brockie-Pell make. The testing apparatus consists of a Wheatstone Bridge in conjunction with a highly sensitive galvanometer of the Sir William Thomson type, with the usual complement of shunts, a reversing key, and a large battery of Leclanche cells giving about 115 volts. Most of the instruments in regular use are attached to a table in the test room of special design, with the connections marked upon the top. The galvanometer stands upon a granite column sunk some 12ft. into the ground to the surface of a hard gravel stratum, the object being to protect the instrument from any vibration which would necessarily interfere with its readings. A complete set of apparatus for restandardising any of the instruments used in the station is also provided, in the shape of a standard current balance, an electrostatic voltmeter, and rheostat resistance, all of the Sir William Thomson pattern. If necessary the house meters can also be readily tested and recalibrated by means of these instruments.

The insulation of the mains is tested by a vacuum tube, one terminal of which is put to earth. If the insulation is good there is a glow in the tube due to the static charges in the conductor, but if there is any defect in the insulation this glow is diminished.

The work has been carried out by Messrs. Hammond and Co., under the supervision of Mr. E. Manville, consulting engineer to the Dublin Corporation, and of Mr. Spencer Harty, City surveyor, assisted by Mr. Mark Ruddle as Clerk of the Works.

ELECTRIC TRACTION IN NEW YORK.

The opposition to the overhead trolley system of electric traction is as stubborn in New York as it is in this country. Nevertheless a line is now being equipped on this system. Its distinguishing feature, to which is probably due the fact that it has been permitted at all, is the attachment of the trolley wire to the structure of an elevated railroad. The way in which this is accomplished will be seen from the accompanying illustration, for which we are indebted to the *Electrical World*. An inverted wooden trough is securely bolted to the iron cross braces of the elevated structure, which are as conveniently placed as if they had been designed for this special purpose. The trolley wire is then carried along the centre of this trough, to which it



Method of attaching Trolley to the Structure of an Elevated Railway.

is attached by means of the insulating fixtures. This not only affords a more substantial suspension than that ordinarily used, but one which protects the wire from rain and sleet and the disastrous swaying of the wind, as well as from falling wires, poles, &c. While possessing these advantages, its simple construction makes it comparatively inexpensive. The expense and trouble of maintaining poles, cross arms, guard wires, &c., is entirely avoided over this portion of the route. The wires, being attached for the major part of the distance to the elevated structure, cannot be said to disfigure the street, as they would not be noticed by the ordinary passer-by, nor could they prove to be an obstruction to the fire department. What is more important, however, they are so completely protected that it is impossible for telephone, electric light, or other wires to fall across them.

HIGH VOLTAGE INCANDESCENT LAMPS.*

BY CAPT. A. DE KHOTINSKY.

In 1881, when I was in Paris, M. H. Fontaine, president of the Gramme Electrical Company, gave me a problem to solve in the construction of high voltage lamps of 250 volts and 200 c.p., limited to absorb not more than 600 watts; his idea was to replace the Jablochkoff candles on the Avenue de l'Opéra. I made several dozen of these lamps, which were submitted to a committee. The result of this test was favourable in all respects, as regards the efficiency and electrical part, but as the committee found it very difficult to watch the lamp during 300 hours (which was stipulated

* Abstract from the *Electrical Engineer* of New York.

Digitized by Google

as the necessary life) they determined to test the lamp only six hours, but with 300 volts difference of potential. The highest life under this condition was five hours and 40 minutes, and for this reason the lamps were rejected; and that was the end of my first experiment with high voltage lamps.

During this test the lamps did not blacken on the inside surface of the globe, only a small blue flame was seen on the positive terminal of platinum near the connection of the filament, which flame, a few minutes before it ruptured, jumped many times from one terminal to the other, and at last short-circuited and melted the platinum below the negative terminal of the filament, and in all cases the filaments were left intact. The distance between the terminals was 1¼in. to 1½in., and the length of filament 18in. in each, two filaments being employed in multiple, which crossed each other at an angle of 90 degrees. The filament was punched out of bristol board, and had a section of 400 square mils; the form of the filament was zig-zag, similar to the Weston 100-c.p. filament of 1883.

In 1882 I found it possible to prepare a homogeneous material for manufacturing filaments which, after carbonising, gave a carbon of specific gravity equal to 1·45. In 1883 I formed a company in Rotterdam, Holland, and built a factory to manufacture my high voltage and high efficiency lamp, but, I am sorry to say, the market at that time was not ready to accept my products.

In 1887 I had an opportunity to introduce my high voltage lamps in Block Station, Neue Friedrichstrasse, Berlin; this station had a capacity of 1,200 lamps 160 volts, from 10 c.p. to 150 c.p. each; this station is working at the present moment. In 1888 I made a contract to light a part of the Brussels Exposition with 600 incandescent lamps and 18 arc lamps, all on a 155-volt circuit; and for my high voltage lamps and entire plant I received a gold medal and diploma of honour. In the same year my proposal was accepted for lighting part of the town of Reims, France, on the three-wire system at 320-volts potential, and in September, 1888, this plant of 1,200 lamps was put in operation and is working now with lamps of from 10 to 32 c.p. and 155 volts each. In 1889 Mr. Medhurst installed 2,000 lamps of 160 volts from 16 to 250 c.p. in the cotton mill at St. Petersburgh and many hundreds in South Russia, all working with Parson's turbo-electric generator. In the summer of 1889 there was a demand for my 220-volt lamp in Marseilles, France, and Barcelona, Spain, where they were employed on the three-wire system, 420 volts being the total pressure.

My company, in Europe, gives an absolute guarantee of 1,000 hours for the lamps of 3½ watts up to 220 volts, and the practice of five years proves that the average life is between 1,000 to 1,100 hours. Lamps of high voltage are certainly more expensive to manufacture, and they cannot be sold for the same price as an ordinary 50 or 100 volt lamp, but the difference is not so great, being only about from 15 to 25 per cent. The increase of price in manufacturing consists of platinum hooks by which I attach the filament to the globe, and also from the extra care with which this lamp must be manufactured.

Regarding the brush discharge between the terminals of the filament, I succeeded in reducing it to practically nothing, by special care introduced in the mode of manufacturing. I must say that the brush discharge cannot be annihilated by increasing the distance between the carbon terminals, as suggested, because, according to my practice, the brush discharge depends mostly on the degree of vacuum, the nature of vapour in this vacuum, resistance of contact between filament and leading-in platinum wire, quality of glass from which the bulb is blown (quantity of metal oxides in the glass) and the specific resistance of the filament.

The Deal Time-Ball.—The automatic drop of the Deal time-ball failed on twelve days in 1891 owing to interruption of the telegraph connections; on one day—November 11th—high wind prevented the rising of the ball; and on February 18th the ball was not raised, as some alterations were being made in the cylinder. On October 19th the ball was dropped eight seconds late through the error in the Greenwich signal. On this occasion it was raised again and dropped by hand at fourteen hours. There were repeated failures in the automatic return signal from Deal last November; and it was ultimately found by Captain Wrottesley, R.E., of the Post Office Telegraphs, that these were due to the accumulation of grease which for many years had been applied to the piston on account of the excessive windage in the cylinder, intended to act as an air cushion. The cylinder was cleaned out, the windage corrected by an asbestos pad, remounted, and on February 18th the ball was dropped by hand at fourteen hours. The signal has since been received regularly.

OBITUARY.

FREDERIC NEWTON GISBORNE.

It is with deep regret that we announce the death, on Tuesday last, at Ottawa, of Mr. Frederic Newton Gisborne, Superintendent of the Canadian Government Telegraph Service, and last survivor of the band of pioneers who were associated with early Atlantic cable promotion. Mr. Gisborne died quite suddenly, having only just returned from his annual tour of inspection. He had, we learn, been much affected by the recent death of several of his old colleagues, and more particularly of Mr. Cyrus Field, and, in a recent letter to us, had pathetically referred to the fact of his being the sole survivor.

Mr. Gisborne, who was in his sixty-ninth year, was born at Broughton, in Lancashire. In 1842 he started on a journey round the world, after which (in 1845), accompanied by his younger brother, he sailed for Canada, and purchased a farm near St. Eustache. He subsequently became one of the first operators of the Montreal Telegraph Company, and opened that Company's first station at Quebec, in the old Merchants' Exchange. The British North American Electric Telegraph Association was then formed for the purpose of connecting the maritime provinces with the two Canadas, and Mr. Gisborne was appointed general manager of the Association, and was deputed to visit New Brunswick and Nova Scotia. His mission was successful, and the Government of Nova Scotia erected a line from Halifax to Amherst. From the spring of 1849 to 1851 Mr. Gisborne was superintendent of the Government lines at Halifax.

In 1851-52 the Legislature of the Island of Newfoundland granted him a telegraph construction charter. He visited New York, and obtained all the capital required for his venture, having previously laid before the Hon. Jos. Howe a project for a transatlantic submarine cable connecting Newfoundland and Ireland. On November 27, 1852, Mr. Gisborne laid the first ocean cable on the Canadian side of the Atlantic, connecting Prince Edward Island with New Brunswick. Owing to a disagreement amongst the capitalists, the Company suspended operations, and Mr. Gisborne again visited New York during 1854, where he met Mr. Cyrus Field, the outcome being the formation of a new company entitled "The New York, Newfoundland, and London Telegraph Company," the incorporation being Peter Cooper, Moses Taylor, Marshal O. Roberts, Chandler White, Cyrus W. Field, and Frederic N. Gisborne. Mr. Gisborne eventually completed the work to the entire satisfaction of the Company, after which period he retired for a time from active telegraph work, and devoted several years to mining engineering and railroad construction. In 1862 he represented the interests of Newfoundland, as acting commissioner, at the London Exhibition of that year, and also at the Paris Exhibition in 1867. In 1879 Mr. Gisborne became superintendent of the Dominion Government Telegraph and Signal Service, a position which he occupied at the time of his death.

Mr. Gisborne was a Fellow of the Royal Society of Canada, and a member of the Council of the Canadian Society of Civil Engineers.

Among the various inventions with which Mr. Gisborne's name was associated may be mentioned the following:—Electric, pneumatic, and mechanical ship signals; anti-corrosive and anti-fouling compositions for the bottoms of iron ships; the electric recording target, improvements in gas illumination, &c.; his semaphore was awarded a gold medal at the Fisheries Exhibition. His latest inventions were an anti-induction cable, an iron telegraph pole with iron cross arms—which have been adopted by the Canadian Government for use on their North-West prairies—and an improved telephone.

Our columns have recently contained articles on the various Pacific Cable schemes, for one of which schemes (the Northern route) Mr. Gisborne was responsible, and in all of which he took a very real interest. He was a most genial man, and will be mourned by a very large circle of friends in Canada and the United States.

STEEL-PLATE PORTRAITS

Of Willoughby Smith, W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, G.C.M.G.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz, Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), and Lord Rayleigh, F.R.S., have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

THE SCIENCE OF EXHIBITING.

Are we not in some danger of taking the Chicago Exhibition too seriously? Our American friends are past masters in the art of advertising, and in this instance it seems to us they have surpassed themselves. Feeling that the thousands of miles which separate Europe from Chicago were, together with the McKinley tariff, facts neither to be explained away nor exactly calculated to arouse an inconvenient amount of enthusiasm, it was decided to play upon our timidity. Ably seconded, it must be admitted, by the technical press on this side of the Atlantic, the promoters of the Exhibition have been these twelve months and more incessantly dinning into our ears that if we refrain from exhibiting next year at Chicago "the glory of England will be extinguished for ever." On the other hand, the puff direct and the puff indirect have been put in motion, and paragraphs minutely detailing in advance the splendours of the World's Fair Columbian Exposition, 1893, have been reeled off in weekly slips. It is, therefore, not surprising that many traders should have succumbed to the attack, and relinquishing their original attitude of masterly inactivity should have sued for space in a somewhat *sauve qui peut* fashion, with the result that, in the opinion of one of the members of the Royal Commission, the most magnificent display ever despatched from this country to any Exhibition is going to be sent to Chicago. As patriotic Englishmen we are, of course, delighted to hear this, and shall be still more delighted to learn that old markets have been safeguarded, or, better still, that new markets have been gained by England's show at Chicago. It is not within our province, nor would it indeed be possible in the space of a single article, to discuss the question as a whole. Each

Digitized by Google

trade must do what seems best in its own eyes. All we would urge is that it is in no case advisable to exhibit in a panic, and that there are other ways of pushing our wares, less showy it is true, but more sure and more scientific.

In this matter as in many others of a similar character, Germany has shown us the way. Much, under the spur of that enterprising country's methods of doing business, has been done and is being done by us to improve our commercial machinery. Organisation never was England's forte; but in this direction, it seems to us, lies our chief hope of retaining our threatened commercial supremacy. On this account we should have preferred to have seen the money, which will shortly be lavished in preparing, despatching, and installing exhibits devoted to purposes such as an agitation for the appointment of men of wide commercial knowledge as consular agents, to the improvement and wider dissemination of consular reports, and to the introduction of some sort of system in many matters of detail where at present the exertions of our "industrials" largely overlap.

But granting that Exhibitions still have their uses, is it not possible to go to work in a more scientific manner? At Frankfort there was a marked tendency to subordinate the natural desire of the individual exhibitor to make the maximum splash to considerations of the general effect. Again, one of the many arguments used to force the laggards into exhibiting at Chicago is that a large number of South Americans will be sure to visit the Exhibition. Let us put the two things together, and consider the outcome. The moral is that we could greatly increase the efficiency of our Exhibition apparatus by bringing it nearer the centre of the area to be supplied, and by arranging its component parts so that potential purchasers should not go away say from the Electrical Department with a hazy notion that while English electrical manufacturers may be all very well for cheap domestic telephonic instruments, they are not to be thought of in connection with high-speed engines and well-made dynamos. In short, Exhibitions should be microcosms of the industries of the country concerned, and not so many testimonies to the success of unabashed advertisers. Exhibitions should be held on the initiative and at the convenience of the exhibitors, and not, as at present, at the beck and call of a rival commercial community. Is it too utopian to look forward to a day when some central commercial body, such, for instance, as the London Chamber of Commerce, will take upon its shoulders the duty of ascertaining from time to time in what countries it would be worth while for such and such English trades to make an exhibit, and then to leave no stone unturned to ensure that before all things there shall be a representative display? Take, for example, these thousands of South Americans, who will, so we are told, travel next year all the way to Chicago, and let us confine our attention solely to electrical engineering. If there is in South America a sufficient demand, actual or potential, for good electrical machinery to justify on that account alone the efforts that have been made to induce the electrical trade to exhibit at Chicago, are we not more likely to secure the trade by a display say at Rio? We should save our South American friends the fatigue of a long journey and we should avoid comparisons, which, as we all know, are odious. Good samples of English engines, boilers, dynamos, motors, mains, lamps, &c., &c., arranged with an eye to the best general effect, would surely be more efficacious somewhere near the equator than on the shores of Lake Michigan.

We do not, therefore, for our own part think that the cold reception of the recent circular addressed to the Electrical Trade is a matter for unqualified regret. It has always seemed to us that, discouraging as were the circumstances under which the manufacturers of the country at large would exhibit, they were doubly so in regard to electrical engineering. Had the Chicago Exhibition executive cared to make the Electrical Department complete they could easily have done so by letting out small portions of the lighting of the buildings and grounds to foreign firms on remunerative terms. In the ill luck which has befallen his proposal, Mr. PREECE will, we trust, console himself with the reflection that he has only met the fate meted out to all men who are so much as five minutes before their time. Exhibiting has not as yet been reduced to a science.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 364.*)

15. Slipping Splice (*continued*).—The most usual practice when paying-out cable from the bows after splicing is to wind back the slack of the splice on the drum, and as soon as the cable is taut and the strain taken by the drum the bow stoppers are removed and paying-out begins. The position of the completed splice is shown in the deck plan in Fig. 53. The end of the submerged cable on which the ship

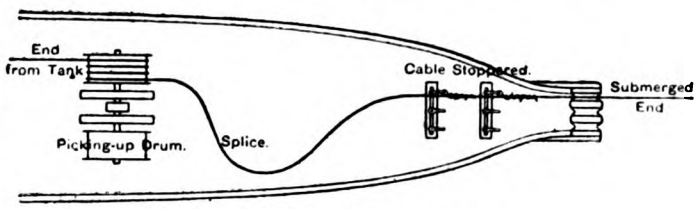

FIG. 53.—Preparing to pay-out.

has been picking up is stoppered at the bows with sufficient slack inboard to make the splice; and the other end from tank is taken round picking-up drum and brought forward for splicing. When the splice is completed, the drum is driven backwards as in picking-up, and the slack bight of cable containing splice is wound in on the drum. The appearance of this on deck is shown in Fig. 54, the slack being taken up, but

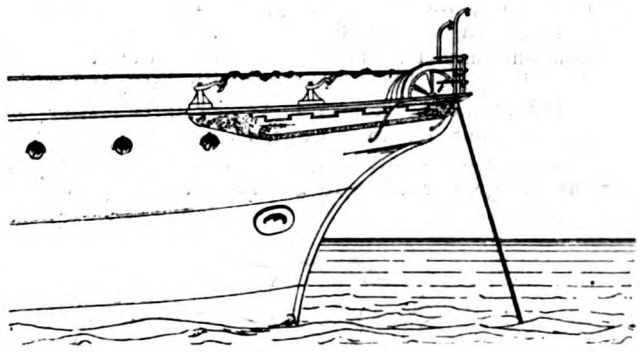

FIG. 54.—Cable stoppered at Bows.

not quite far enough to relieve strain from bow stoppers. A foot or two more heaved in transfers the entire strain from the stoppers to the drum, and this being done the stoppers are removed. The cable is then in a fair way for paying-out.

16. Cable Stoppers.—On cable ships, for use in stoppering cable, two iron frames similar in shape to that illustrated in Fig. 57, are usually fixed about 4ft. apart, close to the bow baulks. The position of these frames on the deck is indicated in plan in Fig. 53. Each frame supports two or three strong wrought-iron hooks, bent downwards as shown in Figs. 56 and 57, and to these hooks are attached the eyes of the rope stoppers used in fixing the cable.

* All rights reserved.

Digitized by Google

The rope stopper is made out of a piece of three or four inch Manilla about twelve feet long. First an eye or loop is made at the centre of the piece, and then the two ends are unlaid and plaited half round sennit, as in Fig. 55. The plaited ends near the eye are somewhat larger in diameter than the original rope, but the plait is gradually tapered down to very small ends, which are tied with a little fine yarn to keep them from opening out. The plaited rope has a much rougher and uneven exterior than the original stranded rope, thus offering a greater surface for gripping the cable; and besides this it is extremely supple, and easily bent round the cable.

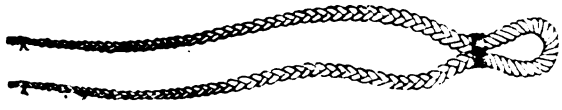

Fig. 55.—Manilla Rope Stopper.

The manner of fixing the rope stopper on to cable is shown in Fig. 56. The cable passes from the bow sheaves immediately over one or other of the hooks. A rope stopper is taken, the eye passed over a hook, and the tails of the stopper taken one on each side of the cable, and held up above the same, one in each hand. They are then crossed and folded downwards over the cable, one end (say, A) overlapping the other (B). They are then crossed and brought up again, this time B overlapping A on the under side of cable. Again crossed and folded down, A overlapping B as at first, and again crossed and folded up, B overlapping A, and so on, up to the end of stopper. This alternate overlapping is shown in the sketch (Fig. 56), exactly as it appears when complete. The tail ends of the stopper are finally bound round tightly to the cable with yarn, and seizings are also put round the stopper in two or three places. Two such stoppers put on to a cable, as indicated in Fig. 54, one behind the other, are ample to hold it in the deepest water, as the greater the pull the more the stopper binds.

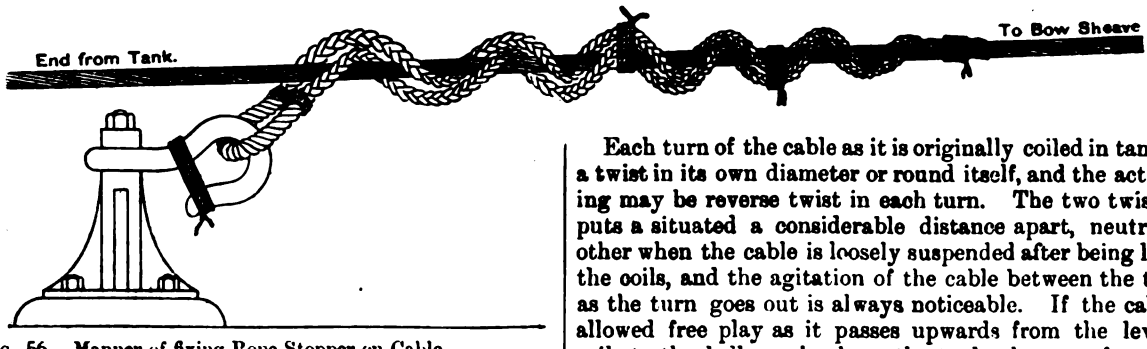

Fig. 56.—Manner of fixing Rope Stopper on Cable.

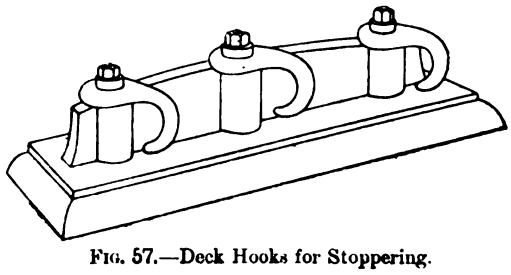

Fig. 57.—Deck Hooks for Stoppering.

When it is required to ease cable out from the stoppers the end seizing is taken off and the two tails held in the hands, when, by easing them bit by bit the cable is allowed to slip through.

17. Paying out.—The ship now proceeds to pay out at a speed of four or five knots, the course being in a direct line for the position of the buoy on the other end. In the testing room watch is kept continuously on a spot of light from the galvanometer, which remains stationary so long as the cable leaves the ship in a perfect electrical condition. Should the insulation fail from any cause the galvanometer would instantly show it, and the ship would be stopped. At intervals the shore is communicated with, and the instructions sent by ship are usually a repetition of "Free one hour, then look out" as paying-out proceeds, The battery on board being connected to cable through galvanometer, only the usual minute current through the insulation can pass while the end on shore is free, and this deflection on the instrument remains constant, unless a fault is payed out.

In the tank careful precautions are taken to prevent the cable "taking charge." Men are stationed below, inside the tank, who see that not more than one turn at a time is lifted, and that the bights between adjacent flakes are properly guided out, so as to avoid kinks forming. In large tanks, by the use of what is known as the crinoline, the cable is guided towards the centre from the moment it is lifted in paying out, and by this means the formation of a kink or a foul flake is of very rare occurrence. The crinoline consists of a set of three or four iron rings of different sizes, the largest being below. These fit over the cone in the tank, as shown in Fig. 58, the cable passing upwards between the rings and the cone. Mr. R. S. Newall, of Sunderland, first introduced the use of the cone and rings in fitting up the earliest cable ships. Before the cone was introduced, it was not uncommon for one of the inner turns to slip down in the centre, and when lifted either jam or form a kink. The cone shown in the sketch is telescopic, so that its height can be regulated to the amount of cable coiled, and thus economise space above cable.

Each turn of the cable as it is originally coiled in tank receives a twist in its own diameter or round itself, and the act of uncoiling may be reverse twist in each turn. The two twists, which puts a situated a considerable distance apart, neutralise each other when the cable is loosely suspended after being lifted from the coils, and the agitation of the cable between the two twists as the turn goes out is always noticeable. If the cable is not allowed free play as it passes upwards from the level of the coils to the bellmouth above the tank, the turn formed by the twists at coiling and uncoiling may not go out, but be carried on further as the cable passes the pulleys on deck. By means of the crinoline the cable is guided almost vertically from the level of the coils to the bellmouth above the tank. The rings, which are of ½in. or ¾in. gas pipe, are fastened rigidly together, as shown in the illustration, and are also attached to guides at side of tank, so that they maintain a central position when being raised or lowered. Blocks and falls are fixed, as shown, by which the men can raise or lower the crinoline according to the height of cable in tank, the position for the lowest ring being about 1ft. or 2ft. above level of cable.

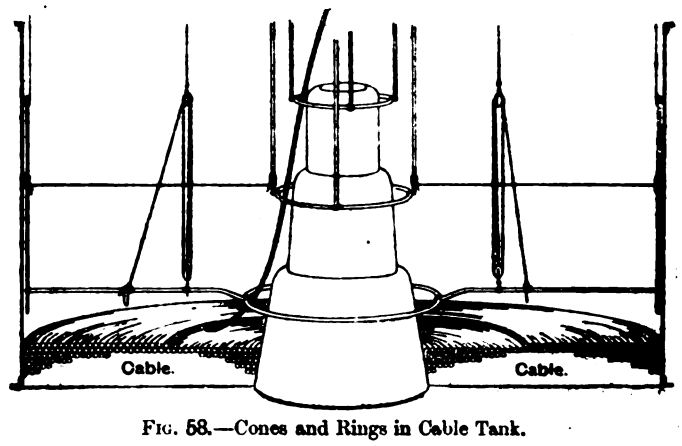

Fig. 58.—Cones and Rings in Cable Tank.

To save time, it is customary to make the necessary splices between coils while paying out is going on. When there is a

Digitized by Google

coil of the required type, uppermost in one of the tanks, and sufficiently long to cover the distance to the buoy, no splices are of course necessary; and this arrangement of cable is

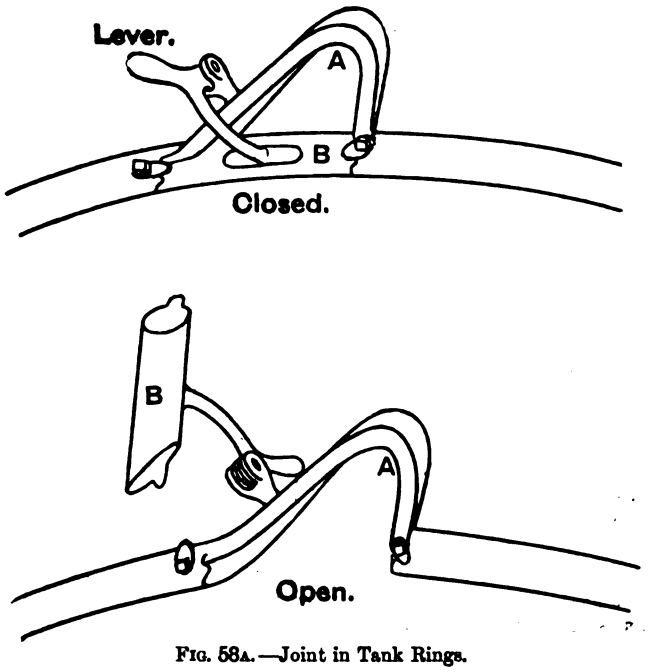

FIG. 58A.—Joint in Tank Rings.

generally made beforehand while ship is steaming out to her first position, the type of cable at the position being well-known. It is, however, sometimes more convenient to relay the cable which has just been picked up, provided it is in good external condition and tests well. If the repair has been simply that of a total break of the cable, it is usual to splice on at once the lengths picked up and relay them, adding on the extra length necessary; but if the repair has been that of a fault, the last length picked up which contains the fault must be coiled in a different tank. And whenever the same cable is relaid after picking up, it generally lies in short coils which, to save time, are spliced together as the ship proceeds, so that when the end of a coil is reached it is only necessary to slow down a few minutes, while bight of splice is lifted instead of waiting two hours. Should it be required to change tanks, that is, to continue the paying out from another tank, the splice is made in the same manner between the underneath end of first coil and the top end of coil in the other tank, but a special arrangement is necessary to allow the bight of splice to lift free of the rings in the first tank. For this purpose each ring is provided with a joint or opening of a similar description to that in illustration, Fig. 58A., the construction of the joint here shown being that employed on the ships of the Silvertown Company, by whose courtesy the sketch is lent. A piece of curved iron (A) is fixed across the gap in the ring, so as to form a loop or pocket when the ring is complete. It will further be seen by the illustration that the short length B of the ring which can be withdrawn to form a gap, or replaced to complete the ring, is moved by a lever pivoted on a bracket fixed to the iron loop A. While cable is paying out the gap in each ring is closed, the short piece B being fastened in by catches, and the underneath end of the coil is passed up through the pocket in each ring formed by the loop A. The end brought out at the top is then spliced on to end in next tank. When nearly up to splice ship is slowed down, and the bight allowed to pass up by opening the gaps in the rings; the movement of the cable is then unobstructed to the next tank, and paying out proceeds at the usual rate. Generally the crinoline is not found necessary in tanks less than a certain size, say 25ft. in diameter. On board the large cable-laying vessels of the Telegraph Construction Company a telescopic guide answering the above purpose has been designed by Captain R. C. Halpin. This is fixed over each tank, and can be raised or lowered by a simple gear.

The brake power applied to the shaft of the paying-out drum is the principal means of preventing the cable running out too fast or taking charge. These brakes are now made with wheels of 6ft. or 8ft. diameter, upon the face of which all round the circumference bear a set of wood blocks fastened to an iron brake band, as in Fig. 59. This band can be tightened by a right and left handed screw, which is operated by a hand wheel. In the cable ship "John Pender" (Eastern Telegraph Company) this hand wheel is on the bridge level, as shown in sketch,

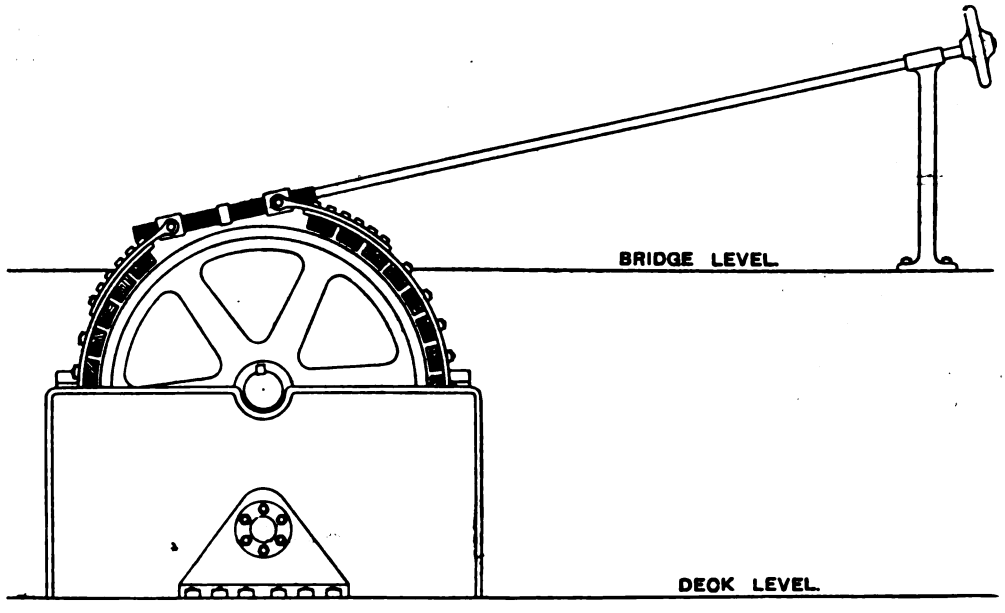

FIG. 59.—Brake on Paying-out Drum.

where the brakesman stands in full view of the cable as it passes out. The brake wheel is kept cool by revolving in a tank of water.

(*To be continued.*)

THE "BRAIN" COVERED CONDUIT SYSTEM OF ELECTRIC TRACTION.

The principal methods of conveying electric power to tramcars or trains are, through the surface rails, through overhead conductors, by means of storage cells in the cars, and through conductors placed in conduits between the rails below the ground level. The system under consideration—the invention of Mr. C. T. Brain, of Liverpool—belongs to the last class but differs in some important details from the usual form in which underground conduits are designed. It is customary to

Digitized by Google

allow of the electrical communication between the car and the conductor by means of an open slot in the top of the conduit, through which the collector, travelling with the car, passes. access to the conductors for repairs; and the ease with which mischievous persons can do damage by poking metal rods through the slot, short-circuiting the current. It may also be pointed out

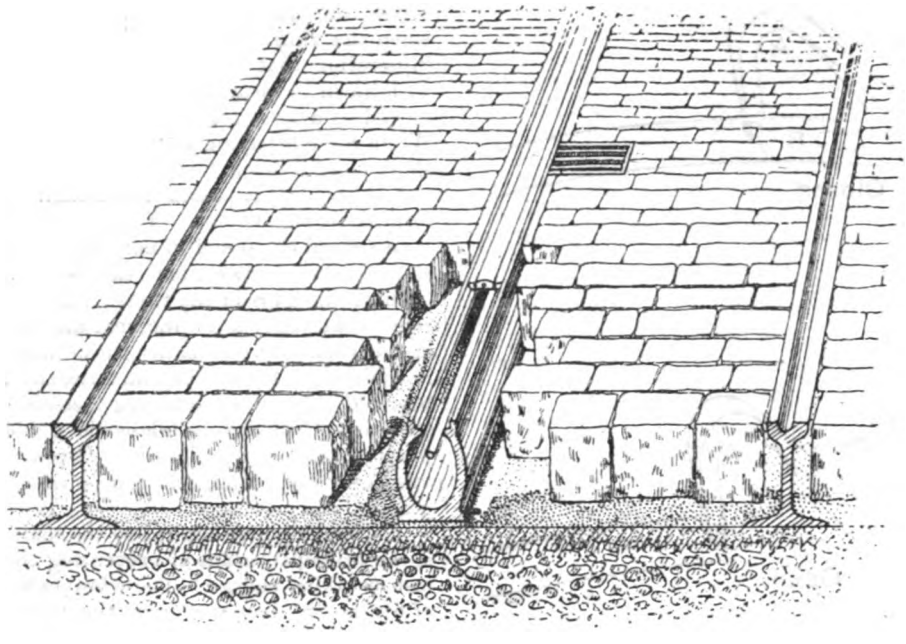

FIG. 1.—Iron Rails and Conduit, showing Cover-Rail, Surface Box, and Conductor.

There are many objections to, and difficulties in working, the open-slotted conduit; and, however superior this form may be

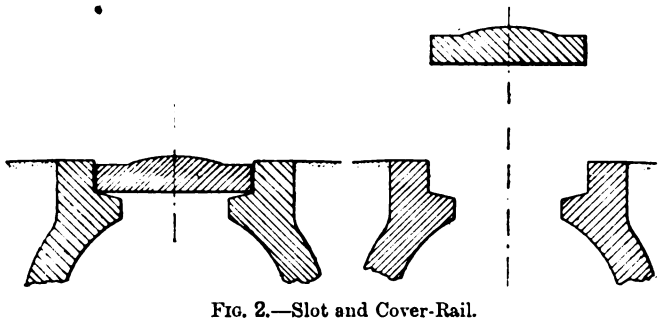

FIG. 2.—Slot and Cover-Rail.

to either of the other forms which have been mentioned, it is certain that success cannot be assured till these obstacles have been surmounted. The difficulties are principally in the admission of dust, mud and rain-water through the slot, choking the conduit, breaking down the insulation, and impeding the passage of the collector over the conductor; the difficulty of that a wide slot is a source of danger to traffic; while a narrow one involves weakness in the collector at the point where it passes through the slot. The Board of Trade limits open slots to a maximum width of half an inch. In the "Brain" covered conduit these difficulties have certainly been overcome, though at some trifling increase of tractive effort.

A general idea of the arrangement in this system is given by the adjoining sketch (Fig. 1), which shows the position of the cast-iron conduit relatively to the ordinary rails of the tramway. Inside the conduit is a solid circular conductor of phosphor bronze, supported at intervals of about 14ft. on insulators, which are accessible through surface boxes. Connection between the car and this conductor is made through a slot 1½in. wide, at the top of the conduit, the edges of the slot being flanged so as to form a seat for the slot-cover or cover-rail (Fig. 2). This cover consists of a flat strip of mild steel of rectangular section, about 1¾in. wide and half an inch thick. When not in use the slot is covered by this cover-rail,

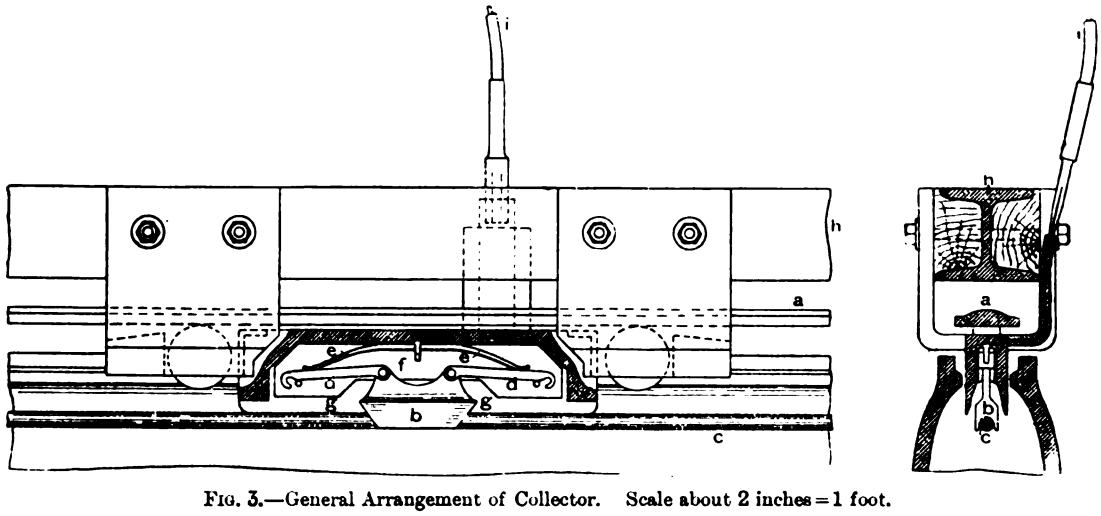

FIG. 3.—General Arrangement of Collector. Scale about 2 inches = 1 foot.

the latter fitting into its seat flush with the road setts. When a car is passing, the cover is automatically lifted about 2in. by the collector, which is fixed to the motor truck of the car. The arrangement for lifting the cover and taking

Digitized by Google

off the current from the conductor is shown in the illustration, Fig. 3. To the girder, *h*, which forms part of the motor truck, are attached four small rollers which press against the under surface of the cover-rail, and two larger rollers (not shown) which press against its upper surface, fore and aft of the other set. These are so arranged that the cover is lifted from the slot by the former set, and replaced by the latter set. The natural elasticity of the rail is found to be sufficient to replace it, but the two top wheels are used as a safeguard. Under the cover-rail, and between the lower set of rollers, is the collector shoe, *b*, which glides over the top surface of the conductor, *c*, and partially embraces its sides, making good contact by means of the springs, *e*, in the lock-frame, *f*. The width of the slot permits of $\frac{3}{8}$in. thickness of insulation on each side of the collector, besides a good thickness of sheathing; conditions which render it mechanically and electrically reliable, and superior to the open slot. Insulation boxes, containing bracket insulators for the conductor, are placed at intervals along one side of the track, and can readily be opened for cleaning and repairs. Each of these boxes is about the size of a granite road sett. At longer intervals there are sumpholes from which the accumulation of mud and dust can be withdrawn after the conduit has been flushed with water.

The cost of keeping up the insulation is very trifling, as the conduit is almost always sealed by the cover-rail; and the little accumulation which takes place can readily be removed by flushing. Every part of the conduit is placed centrally, so as to accommodate cars passing in either direction, without the necessity for any adjustment of the collector. At crossings and turn-outs the conductor is flattened into a broad rectangular strip, on the top of which the collecting shoe glides without embracing the sides of the conductor. By this means the car is enabled to pass along either track without any hitch or jolt at the junction of the conductors. The only mechanism of any sort at these points is most simple, being on the road surface, visible and easily handled. The centre cover-rail is pivoted, like the movable tongue at the points of ordinary rails; being, of course, in the reverse direction, as the pivot is at the centre point of the fork. This short movable strip of cover-rail reaches from the centre point of intersection to the point where the inner edges of the two centre cover-rails meet. These rails being cut off at this point have their ends recessed, or grooved out, the end of the movable tongue being made to swing into these grooves. A short U-piece goes round the conductor and rises up on each side near the end of the movable tongue; a bar connected with this is fitted to the ordinary movable rail points, or any suitable lever fitted in the groove of the rail, so that the cover-rail tongue is always moved to that side which the car wheels are made to take. In the ordinary turn-outs where the rail points are made automatic, the car flanges opening them as they leave the turn-out, the cover-rail tongue is made automatic also. As this tongue swings over to the side which the car takes, its end fits into the end of the cover-rail on that side. When the carrier wheel, or front top roller, is passing the whole works as one continuous rail, just as on a piece of straight line.

One of the most striking features in this system is the easy accessibility of every part of the conduit. The conduit can be opened as fast as a car can be run over the track; for, by a simple adjustment of the top rollers, the cover-rail can be deposited on the road setts, to the right or left of the slot, as the car passes along; thus exposing the entire length and width of the conduit. By running the same car backward over the track, the cover-rail will be picked up and replaced in the slot. The insulator brackets, being all on one side of the conduit, allow of the passage of scrapers or brushes along the conduit when it has been thus opened.

On a length of experimental line which has been laid at the works of the Telegraph Manufacturing Company, at Helsby, this system has been subjected to a series of tests extending over a period of two years. Difficult crossings, sharp turn-outs, and curves have been laid, and the behaviour of the conduit examined in all weathers. It has been found that the power required to lift and replace the cover-rail is so trifling that its cost must be more than met by the saving in other expenses, for even in a severe frost the addition to the tractive force is less than five pounds. In ordinary weather the accumulation of material in the conduit is so small that working order can easily be maintained by nothing more than a water flush once in every two or three weeks; and opening the conduit in the manner described seems to be a rare occurrence. It seems probable that the system designed by Mr. Brain—unencumbered as it is by the heavy loads of the battery system, by the ugly unsightliness of the overhead wire, by the dangers of the conductor rail, or by the mechanical defects of the open slotted conduit—will be an important step towards the perfection of electric traction.

COMPARATIVE MERITS OF THE TWO-PHASE AND THREE-PHASE SYSTEMS.

The latest contribution to the discussion on the relative merits of three and two phases, which has been going on for some little time in the columns of our New York contemporary, the *Electrical World*, and which we summarised in our issue of August 5th, is by Mr. C. E. L. Brown, who writes as follows:—

My extensive experience with multiple-phase currents has shown me that motors for the two-phase and those for the three-phase system for the same output are very much the same machines with regard to their respective efficiency, starting torque, weight, and apparent watt consumption. This holds good for synchronous as well as non-synchronous motors, and shows plainly that Mr. Kelly's, as well as Mr. Steinmetz's theoretical deductions are founded on the true basis.

I make use of this occasion to state that Prof. Ferraris, Gisbert Kapp, and Mr. Tesla also expressed themselves to that effect in an interview I had with them some time ago.

Again, another proof of the correctness of Mr. Kelly's and Mr. Steinmetz's deductions can, I believe, be taken from the fact that Mr. Tesla, who, as is well known, had already in his first patents brought the three-phase current to notice, nevertheless devotes his special attention to the two-phase current system, and I believe rightly, for as soon as there is a question of distributing electric light and power efficiently, there is no doubt that the two-phase has many advantages over the three-phase current.

This latter system allows a very efficient distribution of power only, but as soon as any light has to be supplied in connection with power, the mutual dependence of the currents presents great difficulties in the way of regulation. The connection, too, of the lamps with the mains becomes naturally rather complicated. All electrical engineers know that already the connection to an ordinary three-wire system is comparatively complicated, but these difficulties increase very considerably with the three-phase system, as with this three groups of lamps will always have to be connected with the three wires.

In using the two-phase current all these difficulties are done away with, as the connections of the lamps can be made similar to those on an ordinary alternate current circuit.

The regulation presents no difficulty whatever, and motors can be driven by this system just as well as by using the three-phase current.

It is, therefore, my belief that in the future the two-phase current will take the lead where combined light and power distribution is required, while the three-phase current may be used for simple power transmission and distribution.

The points I have brought up in the above few lines are not to be taken as merely theoretical, but are proved by experience and many actual tests in practice. I have at the present moment installations in hand for many 100 H.P. for the two-phase system, and I am altering a large installation from the three-phase to the two-phase system, as the same is now required for light in addition to the distribution of power, which was originally intended exclusively.

In reply to the remarks of Mr. Steinmetz, that at the Frankfort installation the small number of periods was taken merely at random, I beg to say that this is not the case, but the number of periods was fixed according to very careful and elaborate tests. With this, however, I do not intend to say that motors with larger numbers of periods could not be produced in practice.

TRANSFORMERS.*

BY JOHN PERRY, D.SC., F.R.S.

I. In a transformer with many circuits, of resistances in ohms and numbers of turns, R_1, N_1, R_2, N_2, &c.; let the current at any instant be C_1, C_2, &c., amperes, and let the independent electromotive forces e_1, e_2, &c., volts be maintained in them; let I be the total magnetic induction which threads through all the circuits (10^8 C.-G.-S. units being taken as the unit of induction). The equations to the circuits are—

$$e_1 = R_1 C_1 + N_1 \theta I, \quad e_2 = R_2 C_2 + N_2 \theta I, \text{ &c.},$$

using θ for d/dt.

Multiplying each equation by its N and dividing by its R and adding, we find, using A for the ampere turns, $N_1 C_1 + N_2 C_2 + \&c.$ and q for $\frac{N_1^2}{R_1} + \frac{N_2^2}{R_2} + \&c$

$$A + q\theta I = \Sigma(N_i/R_i) e_i. \quad . \quad . \quad . \quad . \quad . \quad (1).$$

If the law connecting A and I is known, it is possible to calculate I from (1), and then substituting for I in each of the circuit equations, each of the currents is known.

Instead of e_i being the electromotive force in a complete circuit it may be the potential difference maintained at the terminals of a circuit, and the letter V_i will then be used, the resistance between the terminals being R_i. If e_i or V_i has any value the circuit is called a primary circuit. When no independent electromotive force is maintained in a circuit it is called a secondary circuit.

II. Substitution of one coil for two or more:—It is evident from the way in which (1) is derived, that instead of a primary coil (V_1, N_1, R_1) and a secondary (N_2, R_2), if we substitute a primary (V_1, n_1, r_1), and if $n_1/r_1 = N_1/R_1$, and also if $n_1^2/r_1 = N_1^2/R_1 + N_2^2/R_2$, then the currents in all the other coils will be the same as before. We can therefore replace a primary and any group of secondaries by one primary coil.

It is also evident that if any group of secondaries (N_p R_p), (N_t R_t), &c., replaced by one be secondary (n_2, r_2) such that $n_2^2/r_2 = N_p^2/R_p + N_t^2/R_t + \&c.$, all the other currents will remain as before. It is, in fact, evident that if for groups of primaries and secondaries we substitute one primary coil of suitable potential difference at its terminals and resistance and number of turns, all the currents in the remaining coils will remain the same.

If two secondaries of numbers of turns N_p and N_t and internal resistances r_p and r_t have the same terminals, and together supply a current to an outside circuit, for them we may substitute one secondary of n turns and internal resistance r ohms with a permanent short circuit of resistance ρ between its terminals, if

$$n = (N_p^2/r_t + N_t^2/r_p)/(N_p r_t + N_t r_p),$$

$$r = r_p r_t (N_p^2 r_t + N_t^2 r_p)/N_p r_t + N_t r_p)^2,$$

and

$$\rho = (N_p^2 r_t + N_t^2 r_p)/(N_p - N_t)^2.$$

Hence no good results can be expected from compound winding. If, instead of requiring a perfect similarity in all respects, we desire a substitution which is almost absolutely perfect in practical cases, we can obtain it by the use of a single coil with no short circuit outside, and therefore without the excessive waste of power which occurs when two coils of different numbers of turns are compounded. This last result is obtained by regarding A as a negligible term in (1).

Two coils in parallel to one another, used as a primary or secondary, will evidently waste energy in idle currents inside the transformer unless they are exactly equal in their numbers of turns.

III. If condensers are connected with any of the circuits the most general case is this:—Take the internal resistance of the sth coil to be r_s; let it have a condenser outside a capacity K_s in series with a resistance ρ_s'' and let there be a resistance ρ_s' in parallel with ρ_s'' and the condenser. Then, in the general expression, instead of R_s we must use

$$r_s + (\rho_s' \rho_s'' K_s \theta + \rho_s')/\{(\rho_s' + \rho_s'') K_s \theta + 1\}.$$

Having found C_s, we must remember that the part passing through ρ_s' is $(\rho_s'' K_s \theta + 1) C_s / \{(\rho_s' + \rho_s'') K \theta + 1\}$. Everywhere when any resistance r is spoken of, if there be also a coefficient of self-induction l (or in case it is an internal resistance r_s that is spoken of, should there be magnetic leakage), we must use instead of r the expression $r + l\theta$. Our formulæ, in case there is magnetic leakage, in case there is self-induction, or in case there are condensers, really require that a complicated operation

$$\frac{a + b\theta + c\theta^2 + d\theta^3 + e\theta^4 + f\theta^5 + \&c.}{a' + b'\theta + c'\theta^2 + d'\theta^3 + e'\theta^4 + f'\theta^5 + \&c.}$$

should be performed upon a function of the time. Now the functions with which engineers deal are periodic functions, and the evanescent parts of the answers may be left out of consideration. As any periodic function of the time is the sum of simple harmonic functions, we have only to perform the above operations upon functions like $\sin(kt+m)$. But it is obvious that the complicated operation when performed on $\sin(kt+m)$ reduces to

$$\frac{(a - ck^2 + ek^4 - \&c.) + (b - dk^2 + fk^4 - \&c.)\theta}{(a' - c'k^2 + e'k^4 - \&c.) + (b' - d'k^2 + f'k^4 - \&c.)\theta},$$

an operation which is very easy to perform.

Writing it in the form $(p + q\theta)/(a + \beta\theta)$, the result of operating upon $\sin(kt+m)$ is to convert it into

$$\sqrt{\left(\frac{p^2 + q^2k^2}{a^2 + \beta^2k^2}\right)} \sin\left(kt + m + \tan^{-1}\frac{qk}{p} - \tan^{-1}\frac{\beta k}{a}\right).$$

Hence the most complicated cases are readily worked out when numerical examples are taken. Engineers are in the habit of speaking of the epoch m as a lead when it is positive, and as a lag when it is negative. The reciprocal of the periodic time is called the *frequency*, and k is $2\pi \times$ frequency.

IV. Law connecting A and I:—

1. If μ, the magnetic permeability of the iron, is constant, let σ stand for $4\pi a \mu 10^{-9}/\lambda$ where a is the area of cross section of the iron in square centimetres, and λ is the average length of the induction solenoids in centimetres. The curve which on squared paper illustrates the magnetic law is a straight line, and $I = \sigma A$.

2. If the curve is not a straight line, that is, if there is some indication of saturation, and there generally is some saturation where β the induction per square centimetre exceeds 2×10^{-5} (or 2000 C.-G.-S. units), it will be found that a good approximation to actual facts is obtained by assuming that when $I = I_0 \sin x$, $A = A_0 (\sin x - b \sin 3x + m \sin 5x + \&c.)$ where $I_0/A_0 = \sigma$, a constant, and n is any quantity which increases continuously. Thus it will be found that taking only one harmonic, $b = 0{\cdot}2$ gives a close approximation to what may be the actual case in transformer problems. Taking two harmonics, $b = 0{\cdot}2$ and $m = 0{\cdot}05$, gives a better result. There is no hysteresis in such cases.

3. If the curve is a simple hysteresis loop such as may be obtained in slowly-performed cyclic magnetisation, on the assumption that $I = I_0 \sin x$, one of my students, Mr. Fowler, has found A in terms of $\sin(x + e_1)$, $\sin(2x + e_2)$, &c., a rather complicated expression which I need not give. But another student, Mr. Field, finds that the approximation $A = A_0 \{\sin(x + f) - b \sin 3x + m \sin 5x\}$ is sufficiently accurate for many purposes of calculation if $b = 0{\cdot}2$ and $m = 0{\cdot}05$. However complicated the law may be, it can be expressed in the shape:—If $I = \Sigma I_i \sin(i x + e_i)$ then to the ith term in I there correspond the terms in A, $(I_i/\sigma_i)\{\sin(i x + e_i + f_i) - b_i \sin 3 i x + m_i \sin 5 i x + \&c.\}$.

Our first assumption of constant permeability applied to a transformer with one primary and many secondaries causes equation (1) to become $A = (1 + q\sigma\theta)^{-1} N_1 V/R_1$, and hence

$$-C_s = (N_s N_1/R_s R_1)\{\sigma\theta V/(1 + q\sigma\theta)\}.$$

I will, for the sake of illustration, consider a 1,500-watt transformer, which is a specimen of many in use. One primary coil $R_1 = 27$ ohms, $N_1 = 460$ turns. Internal resistance of the one secondary coil $= 0{\cdot}067$ ohm, $N_2 = 24$ turns. Effective primary potential difference $= 2{,}000$ volts or $V = 2{,}828 \sin kt$. Frequency about 95 per second, or $k = 600$, $a = 360$ square centimetres, $\lambda = 31$ centimetres. It will be found that the highest value of β, the induction per square centimetre, is $2{\cdot}755 \times 10^{-5}$ (or 2,755 C.-G.-S. units). If there are neither condensers, nor self-inductions, nor magnetic leakage, and if $\mu = 2{,}000$ (it will not much affect our results to take $\mu = 1{,}500$ or 3,000), then $\sigma = 3 \times 10^{-4}$; if there is no load on the transformer $q = 7{,}837$, and if there is full load, when $R_2 = 6{\cdot}8$ ohms, $q = 7{,}922$. It is evident from these numbers that in practical cases $1 + q\sigma\theta$ is nearly the same as $q\sigma\theta$. Neglecting the 1 means neglecting an alteration of 1/500,000th of the amplitude and lag of 1/200th of a degree. We see that in this case neglecting the term A in equation (1) is quite allowable, and if such a transformer had one primary and many secondary circuits, we might at once write

$$I = N_1 V_1/R_1 q\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$-C_s = N_s N_1 V_1/R_s R_1 q \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Of course, with any law of magnetisation these are the answers if A may be neglected in equation (1).

Taking the third assumption, the simplest hysteresis cycle, which when $f = 0$ is also the second assumption. If $I = A_0 \sigma \sin kt$, (1) gives for V_1 the value

$$V_1 = \frac{A_0 R_1}{N_1}\{\cos f \sin kt + (\sin f + q\sigma k)\cos kt - b \sin 3kt + m \sin 5kt\}.$$

If $k = 600$, or a frequency of 95 per second, the lowest value of $qk\sigma$ for the above-mentioned transformer is 1,411, so that taking f of any value whatever, and b and m even much larger than the values given above, it is obvious that for all practical purposes, certainly

* Paper received March 23, and read May 12, 1892, before the Royal Society.

Digitized by Google

in the case where it is the effective value of V_1, which is important, the above expression for V_1 is the same as if f, b, and m were zero. No doubt V_1 does possess small traces of the higher harmonics; but taking the above values for b and m, and taking $f=20°$, I find that the error in neglecting f, b, and m, in calculating the effective voltage, is utterly insignificant. I have applied to this problem the most complex law of magnetisation which I could formulate, which was at all likely to be true, and in all cases I have arrived at the same result:—Given the voltage V_1 at the terminals of a primary coil of a transformer with many secondary coils, the induction and the secondary currents may be calculated from 2 and 3, which were worked out on the assumption of constant permeability, and in all cases the error in the effective values is exceedingly small.

V. *Magnetic Leakage.*—If all the induction due to the current in any coil does not thread through all the other coils, the effect of leakage is obtained by assuming that each N is really less than the number of turns, and that there is some self-induction in each circuit in addition to $N^2\sigma$. If the additional inductances are l_1, l_2, &c., then, in our expression R_1, R_2, &c., will be replaced by $R_1+l_1\theta$, $R_2+l_2\theta$, &c. Thus, in the above-mentioned 1,500-watt transformer, let I_0 represent the induction when there is no load on the transformer. Assume that 1 per cent. of the induction due to the primary current escapes the secondary, and that 1 per cent. of the induction due to the secondary current escapes the primary, or that $l_1=10^{-2}N_1^2\sigma=0{\cdot}6348$, $l_2=10^{-2}N_2^2\sigma=1{\cdot}738\times10^{-3}$. Let I be the induction at full load, or when $R_2=6{\cdot}8$ ohms. When there is no magnetic leakage $I=0{\cdot}99\,I_0$; when there is 1 per cent. magnetic leakage $I/I_0=(1+2{\cdot}54\times10^{-4}\theta)/(1{\cdot}0108+5{\cdot}08\times10^{-4}\theta)$. Assuming I_0 to be $\sin kt$, I give the values of I for various values of k.

k.	I.
100	$0{\cdot}988\sin(kt-1°{\cdot}4)$
300	$0{\cdot}981\sin(kt-4°{\cdot}2)$
600	$0{\cdot}958\sin(kt-8°{\cdot}1)$
1,000	$0{\cdot}912\sin(kt-12°{\cdot}4)$
2,000	$0{\cdot}782\sin(kt-18°{\cdot}2)$
4,000	$0{\cdot}628\sin(kt-18°{\cdot}1)$

VI. *Eddy Currents.*—There is eddy current loss of power in all the conducting masses near a transformer. If we assume that the induction per square centimetre β is the same everywhere, and if it follows the law β (in C.-G.-S. units) $=\Sigma\, a_i \sin(ikt+\epsilon_i)$, the average power in watts wasted in eddy currents in the iron per cubic centimetre is $6{\cdot}25\times10^{-13}\,r^2k^2\,\Sigma\, i^2a_i^2$, if the specific resistance of the iron is taken to be 10^4. The iron is supposed to be of wire of radius r centimetres.

The average power wasted in the iron is less at high temperatures, being inversely proportional to the specific resistance of the iron. It is evidently proportional to the square of the effective primary voltage in the unloaded transformer, but, of course, magnetic leakage causes a diminution when the transformer is loaded. In fact, the eddy current loss is always proportional to the square of the effective electromotive force in the secondary circuit. In applying the rule, it is to be remembered that the induction is not uniform in the section of a wire, nor is the average induction in each wire the same for all the wires, and, therefore, the real loss of power in the iron by eddy currents is always greater than the result of applying the above formula.* If we assume that one secondary circuit closed upon itself represents all the eddy current circuits, assuming the truth of the above formula is the same as assuming no magnetic leakage between the primary and this eddy current circuit. Assuming magnetic leakage gives the more correct result, which is practically that the magnetisation is greater in wires near the surface of the mass of iron than it is internally, and also that the induction is greater near the skin of each wire.

Such experiments as have hitherto been made do not enable us to say to what extent the eddy current loss is increased by this cause. In the above-mentioned 1,500-watt transformer there is 10 per cent. less eddy current waste at full load than at no load, because of the change in q^2 and also because of magnetic leakage, and there may be 50 per cent. less eddy current waste due to the higher temperature of the iron.

VII. *Unloaded Transformer.*—When there is a fair load on the transformer, the primary current may be calculated on the assumption that the permeability is constant, without much error. But when there is no load, or small load on the transformer, it is necessary to know the law connecting A and I. Everybody who has studied this subject takes A in an unloaded transformer as being N_1C_1. Now, in reality, this is an assumption that there are absolutely no eddy currents; but as there are always eddy currents, however finely the iron may be divided, and even small eddy currents produce great effects upon C_1, the magnetic law which has been deduced from experiments on this assumption must be quite untrue. Taking eddy currents effect as represented by a circuit (n, r) with no magnetic leakage; taking as our magnetic law that when $I=g\sigma\sin x$,

$$A=g(\sin x-b\sin 3x+m\sin 5x).$$

If V is a simple sine function of the time, I is so also with very great accuracy, but not perfect accuracy. Assuming that I is a simple sine function, the neglected terms in V may be calculated; this serves no useful purpose, so far as I can see at present, as they are so insignificant. The only problem of importance is really the calculation of C_1, assuming that with great, but not perfect, accuracy V has the value $V_0\sin kt$. Our equations are $V=R_1C_1+N_1\theta I$ and $0=rc+n0$ I, and hence $N_1V_1/R_1=A+q\theta I$, where $A=N_1C_1+nc$ and $q=N_1^2/R_1+n^2/r$. Now n^2/r is negligible in comparison with N_1^2/R_1 in transformers, and we may take $q=N_1^2/R_1$. Hence $-I=(V_0/N_1k)\cos kt$ very nearly, and if $e=n^2\sigma k/r$, being called the eddy current effect, f being the hysteresis term,

$$C_1=(V_0/N_1^2\sigma k)\{\sqrt{(1+2e\sin f+e^2)}\sin[kt-90+\tan^{-1}(\tan f+\frac{e}{\cos f})]-b\cos 3kt-m\cos 5kt\}. \quad . \quad . \quad . \quad (4)$$

We see that the effect of eddy currents without hysteresis is to increase the amplitude of the fundamental term in C_1, and to produce a lead of $90°-\cot^{-1}e$, whereas the effect of hysteresis without eddy currents is to keep the amplitude unaltered, and to produce a lead f. If f is put equal to 0, that is if we assume no hysteresis, we obtain results which seem to be in accordance with such experimental observations as have yet been made.

The effective current C′ (if V′ is the effective voltage) with constant permeability is $V'/N^2\sigma k$; with hysteresis (or with no hysteresis but some saturation of the iron) but no eddy currents, $C'=1{\cdot}02\,V'/N^2\sigma k$, taking b as $0{\cdot}2$; with eddy currents and hysteresis $C'=V'\sqrt{(1{\cdot}04+2e\sin f+e^2)}/N^2\sigma k$.

The average power given to the choking coil or average value of VC is $V'C'\dfrac{e+\sin f}{1+e^2+2e\sin f}$, neglecting the small terms due to b and m.

Probably, in transformers there are always traces of the term in $3kt$ and the higher harmonics in both V and I, but they certainly must exist in either V or I, whether the transformer is loaded or unloaded. In the loaded transformer, magnetic leakage causes considerable diminution in the higher harmonics of I, and this may increase them in V.

It seems that in a choking coil with a finely-divided iron core, we have found what has been long looked for, a method of increasing frequency by mere magnetic means. A condenser shunting a non-inductive part of the circuit would receive currents in which the higher harmonics would be greatly magnified in importance. To show the magnitude of the terms in (4) I will take the above-mentioned 1,500-watt transformer, in which $q_0=7783$. Taking $f=0$ or no hysteresis, the power wasted in eddy currents being $n^2V_0^2/2rN_1^2$, let this be 40 watts; then $n^2/r=2{\cdot}1168$ when $V=2{,}828$. The eddy current coil therefore which would replace all the eddy current circuits is a coil of two turns whose resistance is about 1·9 ohms, short circuited on itself.

$e=0{\cdot}38$ if $k=600$. Assuming constant permeability and no eddy currents and no hysteresis $C_1=0{\cdot}07398\sin(kt-90°)$, with some saturation and eddy currents but no hysteresis

$$C_1=0{\cdot}07911\sin(kt-69°{\cdot}2)-0{\cdot}014796\cos 3kt-0{\cdot}003695\cos 5kt,$$

I have taken $b=0{\cdot}2$ and $m=0{\cdot}05$.

The primary potential difference V is never a simple sine function of the time. Besides the important term in $\sin kt$ there are small terms of higher frequency, and at least one term of lower frequency equal to the number of turns of the armature per second. The tendency of the forces acting on coils in series on an armature is to produce greater dissonance at greater loads; but it may be assumed that in good machines the fastenings are sufficiently rigid, and the coils and pole pieces so nearly alike that there is always very little dissonance.

The primary potential difference, instead of being $2828\sin 600$ in the above case, may be

$$V=100\sin 20t+2823\sin 600t+200\sin 1800t,$$

the effective potential difference, as measured by a voltmeter, being the same in the two cases. The induction, if there is no magnetic leakage, will be

$$-I=(N_1/R_1q)(5\cos 20t+4{\cdot}7\cos 600t+0{\cdot}11\cos 1800t),$$

the term which was so insignificant, which had only 1/800th of the importance of the most important term in practically estimating the

* [*Added April* 29, 1892.—I have often urged the importance of the consideration of the want of uniformity of induction in the iron; but even in February last, when I brought it before a meeting of the Institution of Electrical Engineers, it was looked upon as unimportant, and I had made no calculations which would enable me to prove its importance. The calculations of Prof. J. J. Thomson concerning the eddy currents in thin plates, published in *The Electrician* of April 8, 1892, place the matter beyond doubt.]

Digitized by Google

volts, is now greater than what is usually taken to be the greatest term when we come to deal with the actual induction. Magnetic leakage will not much affect this condition of things, but it will greatly diminish the importance of the higher harmonics.

When experimenters say that they keep the primary volts constant, they mean that they keep the effective primary volts constant. It is obvious from the above considerations that different methods of keeping effective volts constant will produce very different kinds of induction. The effects produced by an exciting current in a choking coil or unloaded transformer are evidently very complicated. Let the dynamo have a perfectly pure simple harmonic law of electromotive force; we have seen that even when no hysteresis is assumed, the current will possess large harmonics and the induction possesses corresponding harmonics. The energy wasted in the creation of these harmonics may be called "hysteresis" loss, but it cannot be altogether the same as the hysteresis loss in slowly-performed cycles of magnetisation; it will be different if the dynamo does not follow a simple harmonic law in its electromotive force, and the apportioning of the small higher harmonics to the primary voltage and to the induction must greatly depend upon the self-induction of the dynamo machine.

POST OFFICE TELEPHONE INSTRUCTIONS.

The following circular (E. 130) recently issued from the Engineer-in-Chief's office of the General Post Office may be of interest:—

Telephone Circuits.

The extended use of telephones by the department, especially in substitution for A. B. C. instruments, appears to call for the issue of more definite instructions than have hitherto been given with regard to the arrangement of telephone lines. The following rules have therefore been drawn up:—

1. All direct telephone circuits which have line resistances of less than 200ω are to be worked without relays.

2. A departmental telephone circuit serving sub-offices may generally be "single-wire" if fairly free from induction disturbance; but only under exceptional circumstances should single-wire circuits be granted to private renters.

3. It is often difficult at out-of-the-way places to secure good earth for single wires, and it has become necessary therefore to recognise that an "earth" may have an appreciable resistance; but every effort should be made to ensure that this does not exceed the limit of 10 ohms laid down.

4. On double-wire circuits, where there are more than two telephones in circuit, the "bridge" system is to be generally employed. On single-wire circuits, where there are more than two telephones in circuit, the "leak" system is to be adopted.

5. The "bridge" and "leak" systems have the following advantages:—

(*a*) A disconnection in one telephone does not prevent the others from communicating;

(*b*) The electro-magnets not being in the direct circuit, the speaking efficiency of the whole line is not materially affected by the number of offices; and

(*c*) Bells without relays can generally be used.

6. When, on a single-wire circuit, an intermediate office is off the main line, and has to be reached by a branch, it is necessary to have only a single wire (not a loop) for the branch. In cases where the branch is so short that only a leading-in wire is required the same rule holds good. The same principle applies also to double-wire circuits, two wires (one from each of the main line wires) being used for each branch. It may be noted that this does not apply at offices where intermediate switches are to be fixed.

7. Bells without relays:—

(*a*) These may be applied in *all* cases where there are only *three telephones* upon a circuit, provided that the joint resistance of the ringing circuit from any telephone does not exceed 150ω.

(*b*) They may also be used with *any number* of offices on a circuit, provided that the line resistances between the offices are fairly uniform and do not exceed (say) 20ω in each section. When bells are not worked from a relay, their coils should invariably be joined in series.

8. As the current divides in inverse ratio to the resistance, it is desirable, for ringing purposes, that the several arms of a circuit shall not be very unequal. In the case of a "three-office" circuit balancing resistances should be inserted if necessary in both the shorter branches. The resistance coils should be so connected as to be out of circuit both for speaking and for the outgoing ringing current (Figs. 1 and 2). The advantage of this arrangement is that the introduced resistances do not involve any increase of battery power, although the ringing currents received by each office from either of the others are practically equalised.

9. Where there are more than three offices upon a circuit:—

(*a*) If the resistance between any one office and the next is small (say not more than 20ω) no balancing resistances need be used and bells will suffice.

(*b*) If the resistance between the two or more intermediate offices is small and the resistance of one or more of the terminal arms is considerable, then *all* the terminal arms should be balanced so that each has approximately the same resistance. It should be borne in mind that on the "bridge" or "leak" system, the *second* office at each end is practically terminal as well as the first, and must not for the purposes of this rule be considered "intermediate." Thus, *all* offices on a circuit with four instruments are "terminal" (Fig. 3.)

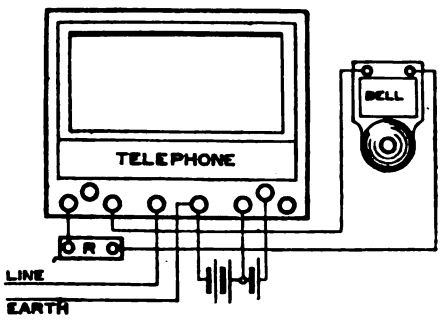

Fig. 1.

(*c*) When the resistance between the intermediate offices exceeds 50ω, so that it must be taken into account, it is necessary to use a high-resistance (1,000ω) relay at each office. The line resistances of an ordinary telephone circuit are generally so small in comparison with 1,000ω that they need not be taken into account when this relay is used; and, as the relay is made more sensitive so that the working current is reduced from 16 milliamperes to seven, the introduction of the high resistance is to some extent compensated.

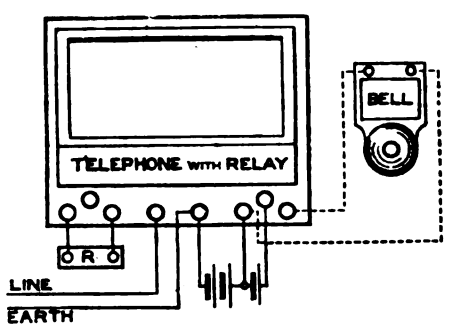

Fig. 2.

High resistance relays will now be supplied on requisition. They are ordinary telephone relays specially wound to 1,000ω and may be had either mounted or unmounted, like the 100ω relays.

(*d*) If, with 1,000ω relays, the resistance of one terminal arm, in a case where more than three offices are in circuit, should be more than 150ω in excess of that of any other terminal arm, it is advisable to insert balancing resistances until the resistance of each arm of the circuit is within 50ω of the resistance of the arm in question.

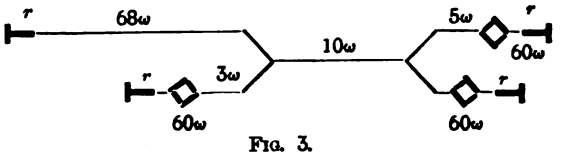

Fig. 3.

10. The battery-power must be so regulated that each office may receive the standard working current according to the following scale:—

Bells (100ω) ...	...	...	...	25 milliamperes.
Relays (100ω)	...	...	...	16 ,,
Relays (1,000ω)	...	...	...	7 ,,

Calculation of the Battery Power.

11. (*a*). It must be remembered that the balancing resistance at the calling office is not in circuit. (*b*.) Care must be taken to ensure that the office *least* favourably situated with regard to the calling offices will get sufficient current. (*c*.) On single wire circuits the resistance of each earth may be assumed to be 10 ohms (unless, of course, it is known to be greater). (*d*.) The electromotive force of a Leclanché cell may be taken as 1·2 volt and its resistance as 4 ohms.

Digitized by Google

12. For offices where not more than nine cells are required No. 1 size should be used, but where more than nine cells must be fixed, then two cells of No. 1 size should be used and the remainder of No. 3 size. No. 1 size cells are fitted in boxes of 2, 3, 4 and 5; No. 3 size in 6, 8, and 10.

13. The method of calculating the battery power will be best understood from the following example, showing the complete calculations (with remarks) for a four-office circuit of high resistance with 1,000ω relays and no balancing resistances. (Fig. 4.)

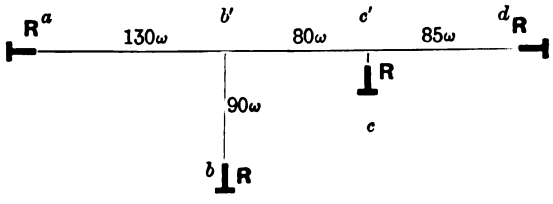

Fig. 4.

[If the resistance of the arm $a\ b'$ or $b\ b'$ exceeded 150ω, balancing resistances would have to be applied under paragraph 9 (d), because c (with an arm of no resistance, except 10ω for earth, which is negligible) is practically as much a terminal office as d.]

(i.) Ringing power for a:—

Joint resistance $c\ c'$ and $c'\ d = \frac{1010 \times 1095}{1010+1095} = 525$ (say 520^{ω}).

Total resistance of arm $b'\ c\ d = 520^{\omega} + 80^{\omega} = 600^{\omega}$ . . . (1).

Joint resistance of $b'\ b$, and $b'\ c\ d = \frac{1100 \times 600}{1100+600} = 388^{\omega}$.

Total resistance of ringing circuit from $a = 388 + 140 = 528^{\omega}$ (2).

Now, at b' the current from a will divide in the ratio of 600 to b and 1100 to c and d; that is, c and d will get $\frac{11}{17}$ of the current sent from a. Of this, c and d will get respectively in the proportion of 1095 and 1000; that is, d will get $\frac{1000}{2095}$ of $\frac{11}{17}$ of the current sent from a; and this, for a 1000ω relay, must be not less than 7 milliamperes; therefore the total current from a must be

$$7 \times \frac{17}{11} \times \frac{2095}{1000} = \frac{49861}{2200} = 22 \text{ milliamperes};$$

and (as E = C R, and R in this case is 528^{ω}) the electromotive force required at a is

$$E = \frac{22 \times 528}{1000} = 11{\cdot}716 \text{ volts.}$$

It follows that the battery power at a should be at least 10 Leclanché cells; but as the resistance of the battery is not taken into account, and the 10 cells do not give much margin, 11 cells might be fixed in this case. [In determining the power for b, c, and d, a more practical method (with simply approximate figures) will be followed.]

(ii.) Ringing power for b:—

We know from (1) that the total resistance $b'\ c\ d$, is 600ω.

Joint resistance $b'\ d$ and $b'\ a = \frac{600 \times 1140}{600+1140} = 393^{\omega}$. (3).

Adding 100ω for resistance $b'\ b$ we have,

Total resistance of circuit from $b = 493^{\omega}$. . . (4).

Now, each of the other offices is to get 7 milliamperes; b must therefore send 21 milliamperes.

Therefore, E.M.F. required at $b = \frac{21 \times 493}{1000} = 10{\cdot}353$ volts or 9 Leclanché cells. [The closer calculation would have brought the same result].

(iii.) Ringing power for c:—

First determine the joint resistance of $b'\ a$ (1140ω), and $b'\ b$ (1100ω). These two arms are so nearly alike that we may safely assume their joint resistance to be their sum divided by 4, which is 560ω.

And therefore total resistance of arm $c'\ b\ a = 560^{\omega} + 80^{\omega} = 640^{\omega}$ (5).

Joint resistance of $c'\ a\ b$, and $c'\ d = \frac{640 \times 1095}{640+1095} = 403^{\omega}$. (6).

= total resistance of circuit from c.

Therefore E.M.F. required at $c = \frac{21 \times 403}{1000} = 8{\cdot}463$ volts. 8 Leclanché cells should therefore be taken.

(iv.) Ringing power for d:—

The resistance of $c'\ b\ a$ is known (5) to be 640ω. Therefore the joint resistance from $c' = \frac{640 \times 1010}{640+1010} = \frac{16000}{41} = 391^{\omega}$ (say 390^{ω}) . (7).

And (adding the resistance of section $c'\ d$) the total resistance from $d = 485^{\omega}$ which is so close to that from b (493^{ω}, *see* 4) that we may at once assume the power to be the same, namely, nine Leclanché cells.

14. In the following illustrative diagrams ⊣ represents a telephone with direct bell; ⊣ a telephone with 100ω relay; and ⊣ a telephone with 1000ω relay.

(h.) *Multiple-Office Circuit with 1000ω Relays and Balancing Resistances.*

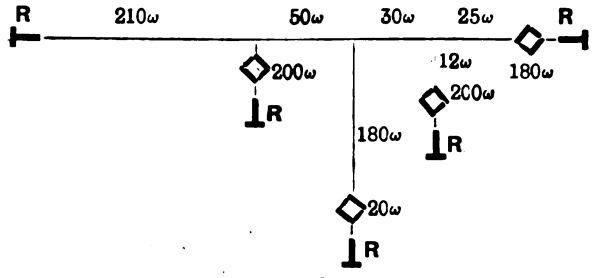

FIG. 12.

[In this case one terminal arm (220ω with earth) is more than 150ω in excess of any of the other three (which are 10, 22, and 35). All are therefore approximately balanced.]

15. The diagrams on works estimates for telephone circuits should, in all cases, be figured as above with the resistance of each section of the line.

16. On some departmental circuits and at coastguard stations it is often desirable that there shall be an indication of the outgoing current and also of the incoming current independently of the bell or relay. It is therefore proposed for such circuits to issue "tele-

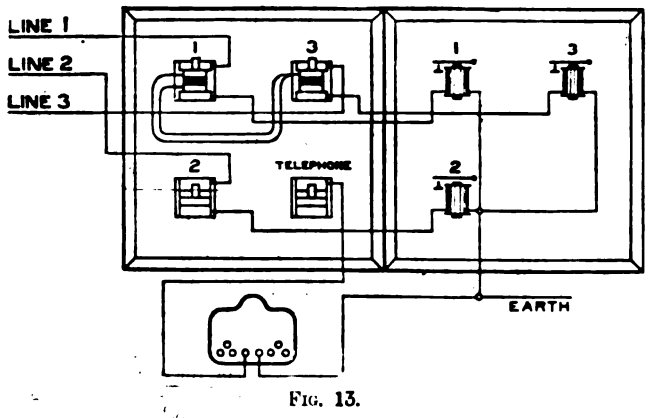

FIG. 13.

phone galvanometers." These will probably be non-polarised magnetic indicators wound to a resistance of 3,000 ohms, and they will be connected (in bridge or leak) direct on the lines so as to be always in circuit. This will necessitate a slight increase in ringing-battery power. It may be taken that for circuits fitted with 1,000-ohm relays one-third more current should be allowed to each office; and where bells or 100-ohm relays are used the increase will generally be very slight indeed, depending, of course, partly upon the balancing resistances that may be used.

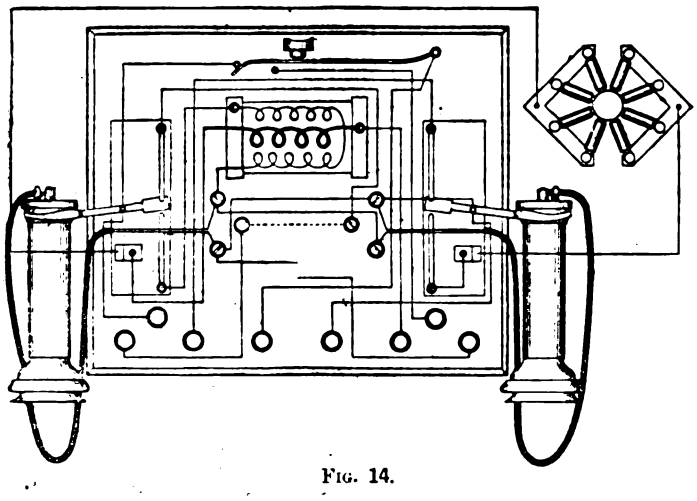

FIG. 14.

17. In arranging departmental circuits for the transaction of public business it is often convenient to group them into a small exchange; in which case the connections should be so arranged that the several stations may either be placed in communication with one another or speak direct to the exchange. The connections shown in the subjoined diagram of a single wire system are so arranged that when two circuits are put through the indicator of only one line is left in "leak. (Figs. 13 and 14.)

At one end of the flexible cord the two conductors are attached one to each side of the peg, and at the other end *both* conductors are connected to the *upper* side of the peg.

18. As such departmental exchanges are likely to include circuits of very various resistances, which (from the nature of the circumstances) cannot be compensated for, it may be taken as a general rule that, wherever any circuit on such an exchange embraces two offices, the whole system should be fitted with 1000ω relays; and 1000ω non-polarised indicators should be fixed at the exchange.

19. Where only two circuits are led into a "central" office it is not necessary to fit an exchange switch with pegs. A "bridge intermediate switch," which is simpler and much cheaper, will suffice.

20. The attention of telephone operators should be directed to the fact that in case of failure of their microphone (which is indicated by their being able to hear distinctly, while they cannot be heard) they should endeavour to speak through the receiver.

21. The question as to whether more than one telephone is wanted at the exchange will be best determined by local circumstances; but it should be recognised that, to safeguard against breakdown of the exchange system owing to a fault in the exchange telephone, two telephones should be fitted when more than four circuits are connected.

II.—Post Office Telephone.

22. A new telephone manufactured by the Department is now being issued. This instrument consists of the Gower-Bell transmitting arrangement of carbon pencils mounted on a smaller diaphragm without a mouthpiece, and two Bell telephones which serve as receivers in place of the Gower-Bell receiver and tubes.

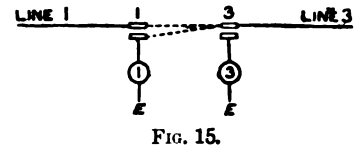

FIG. 15.

23. Each Bell receiver is wound to a resistance of 120 ohms, approximately, and the two are connected in parallel circuit.

The resistances of the new induction coils are:—

Primary	5ω
Secondary	150ω

24. The connections are uniform with those of the Universal Gower-Bell Telephone, and they are arranged to be used with or without a relay inside the case.

Other paragraphs relating to requisitions and other purely departmental matters follow.

BRITISH ASSOCIATION.

DISCUSSION ON A NATIONAL PHYSICAL LABORATORY.

A discussion upon the subject of the need for a National Physical Laboratory was held in Section A on Monday, August 8th. Prior to the actual opening of the discussion by Prof. Oliver J. Lodge, the President (Prof. Arthur Schuster) said Prof. Schoute had a Paper to read which had some relation to the subject, as it showed what had been done in another place in a direction similar to that which Dr. Lodge proposed should be taken in this country.

* Remarks revised by Speakers.

Prof. P. H. SCHOUTE then read a Paper on "The Construction of the New Physical Laboratory at Groningen, Holland." He said two special points had been kept in view in the design and construction of the buildings he would describe, these being that they should be thoroughly fitted both for instruction and for investigation. With regard to design, there was a class-room fitted up for 100 students; separate rooms were provided for instruments, and there were special laboratories on the ground floor for young students. In the construction the things chiefly aimed at had been the avoidance of disturbance from traffic and interruption due to sunlight, a good foundation and the absence of iron. To eliminate as far as possible all effects of vibration, the instruments were so placed as to be quite independent of the floors of the fabric itself. A solid stone foundation was laid, which occupied very nearly the whole of the floor space, but was clear of the walls on every side. Upon this foundation were erected a number of stone piers. The floor was supported on beams fixed to the walls, but over the piers were movable slabs one metre square, which could be taken up so as to allow of the instruments being placed directly upon the piers. An instrument could thus be placed in any part of the room, and yet be almost entirely free from any disturbing effects.

The PRESIDENT bespoke the thanks of the Section for Prof. Schoute's Paper, and said they would pass on to the discussion of a similar project

Digitized by Google

for this country. Prof. Lodge, President of the Section last year, in his presidential address, suggested the establishment of a National Physical Observatory, and it might be well to follow up that suggestion with a short discussion this year, so that they might know how far the different members of the Section were really agreed as to the advisability of facilitating the institution of any such observatory. Last year a committee was appointed to report on the subject, and the report of the committee would be taken in conjunction with Prof. Lodge's remarks.

* Prof. LODGE: The report is merely a formal thing, because the committee, as a matter of fact, have not met. The committee was appointed at Cardiff, and a circular was sent round asking for information and correspondence, and a certain number of answers were obtained; but on the whole it was thought wiser to wait for a further discussion before anything was seriously undertaken. If anything is going to be done it is not going to be done in five minutes, possibly not in five years, and there is not any special hurry. This is a good opportunity to discuss the matter, especially as we have the presence here of several Continental philosophers. The idea I wanted to bring before the Section is the question of the advisability of establishing a National Physical Laboratory on the lines of some institutions abroad, and on the lines of the Greenwich Observatory in these islands. So much work is done in this country which is done in Universities and by amateurs which might more easily and with more economy of brain power be conducted by a permanent staff, a staff established through a regular National Laboratory, under the lead, directly, of some eminent man of science, no doubt, but also under the guidance of a committee of the Royal Society, as the Greenwich and Kew Observatories are now carried on. But there is not the remotest chance of carrying conviction to any British Government unless we have the support of Lord Kelvin. A science in its infancy may be and must be grappled with by the scientific amateur, or at any rate by the isolated individual. To explore new and savage territory heavily armed troops are unnecessary and inefficient. As our President told us, a heavy weight of learning is an encumbrance, and we look to the free lances and skirmishers of science for the striking out of fresh fields of investigation. But as a science becomes adult, as it reaches the stage when minute accuracy becomes possible and desirable, the labours of the amateur in those branches get increasingly difficult and inefficacious. A great weight of learning is now no longer an impediment, but an essential; heavy armed troops can now fulfil their proper function, and we have need, even, of the artillery or great guns of science. But the greatest men of science, as of every other department, are and must be few; their proper function is that of generals, of commanders. There is in this country too much tendency to keep everyone in the ranks, or at most to make him a corporal, with a command of four or five assistants, whom he must train himself. If he undertakes investigation he must do it in the intervals of teaching, sometimes of examining; and even when circumstances relieve him from that fatigue drill he must always work essentially as an amateur, taking up and dropping investigations according as his interest in them waxes or wanes, and leaving nothing to a successor but example and, perhaps, inspiration.

Now this free and amateur way of cultivating science has its advantages. Our President maintained this, and I not only admit it but strongly feel the truth of the statement. It has its advantages; but it has also some disadvantages. Some men can and always will work best in that way: others could do better as heads of a great establishment with an organised staff and thorough equipment. For these latter men, so far as physics is concerned, we have no provision in England. Abroad it is otherwise; but I shall leave it to others to speak of abroad, I elect to speak only of the British Isles. But in the British Isles other subjects are not so ill provided as is physics. Astronomy has had the Greenwich Observatory for centuries, and by private munificence or Government endowment there are several other observatories. What I may speak of vaguely as the observing or the natural history sciences have that great institution the British Museum in its various departments, and for biology specially those sumptuous new quarters at South Kensington have been erected. For geology there is the well-equipped staff of the Geological Survey, and so on. But for physics, what is there, except the old universities, the new university colleges, and a teaching college at South Kensington? Of the work done by such bodies it is impossible to speak too highly. A great deal they do, and will always, I hope, continue to do, in the direction of pure research; but I urge that there are many, very many, investigations for which they are unsuitable, and which they can only undertake at disproportionate labour and sacrifice. If Greenwich Observatory and the Nautical Almanack did not exist, if the observation and reduction of transits had to be executed by amateur observers at fitful intervals, how great would be the waste of power, and how painfully feeble the result! The universities and colleges have plenty of work lying to their hand. They stand intermediate between the amateur on the one hand and the highly-equipped Reichsanstalt and Bureau des Poids et Mésures or National Physical Laboratory, on the other. There is room for all three arms of the service—the cavalry, the infantry and the artillery—and one cannot satisfactorily perform the work proper to the others. There is much work for which it would be disgraceful to use our greatest men. If it is a relaxation to Lord Rayleigh to weigh hydrogen for a few years, well and good; but it is work more suited to the staff of a National Laboratory under his direction. A great number of precise and accurate observations can only be carried out by the patient and continuous labour of trained and competent observers for a year or two. For all, or for many, such trained and competent observers, places would be found in the National Laboratory. They need not be men of genius; they must be men of care, of precision, of system, and of ability. Such men are not, indeed, common; but there must be hundreds of them for one great man of genius. Isolated as they are now, they often do not know in what direction to work. Though not, perhaps, specially original or brilliant, they are sound and thorough workers, but they want a leader. Utilise these men, and do not waste them. Establish a great National Physical Laboratory, where congenial work can be found for them, and there they will gradually find their level, whether it be high or low.

Of the work that should go on in such an institution much might be said if the matter were seriously considered; but by way of reminder I may indicate the types of work which everyone will admit to be suitable; and first of all, the place which has done work most allied to the sort I contemplate has been the Cavendish Laboratory at Cambridge. There Lord Rayleigh spun the ohm, there Mr. Glazebrook watches and compares the standards, there much other work of high accuracy is carried on by the men reared in that splendid University. Here, again, Prof. Tait squeezed thermometers for the "Challenger" expedition, and incidentally worked out some of the properties of water. Nearly all that class of work might appropriately have been conducted in the National Laboratory. Fresh determination of the ohm, measures of V, of standard electrochemical equivalents, of J or the specific heat of water, of the gravitation constant; all these things, now going on in various parts of the island, are more appropriate to a central or Government institution, with every possible appliance and aid to accuracy, with absolute standards ready for use, with rooms which can be set aside to a special purpose for several years, or, if necessary, for several centuries, and a staff of skilled assistants, one or two of whom can be detailed off to conduct each investigation to a full and satisfactory conclusion. An investigation in progress need not then be dropped by reason of lapse of interest on the part of the investigator, or his decease or removal. The staff will be immortal, and any research determined on and ordered by the head or by the governing committee may go on for precisely as long as their judgment decides to be right. Nearly all the work of Regnault was carried out under circumstances something like those I advocate, and to an amateur such work would have been practically impossible. The apparently simple operation of filling and weighing a column of quicksilver and measuring its resistance per cubic centimetre with accuracy is a thing of surprising difficulty. Not only could no amateur hope to do it, but it eluded Lord Rayleigh himself. No one without access to a standard meter and a standard kilogramme could attempt it, and a re-determination of the density of water would be necessary before the contents of the tube could be measured. After that the difficulties would begin. Prof. von Helmholtz, Dr. Lindeck, and the staff of the Reichsanstalt, have done something towards it; M. Guilleaume and others, at Paris, have attacked another part; and the workers in the Cavendish Laboratory, and many parts of the world, a third part; but even with all that heavy artillery the thing has not been yet accomplished.

Classes of work appropriate to the National Laboratory are—(1) extremely accurate determinations of fundamental quantities, like V, the ohm, &c.; (2) determinations of physical constants and properties of materials (what I may call Regnault work); (3) maintenance of standards and issue or verification of stamped and certified copies of the same for scientific or industrial use; (4) continuous record of certain phenomena, supplementing but not necessarily interfering with the similar work of Greenwich and Kew; (5) undertaking certain determinate lines of research, especially such as are likely to last many years or centuries, and carrying them to a definite conclusion; secular experiments on the properties of solids, such as have been begun at Glasgow, but nowhere else that I am aware of. Pioneering work, such work as that of Faraday, and others living who could readily be mentioned, the National Laboratory could not usefully undertake; it would be devoted to the dryer and more thoroughly ascertained facts of science, and almost entirely to quantitative research. Work of genius, again, though quantitative, like that of Michelson, it would be too much to expect from any institution, though it might sometimes be forthcoming; but much of the careful and laborious work now done by amateurs might be undertaken at such a laboratory if it existed, and, merely by way of example, I have taken the last four volumes of the *Philosophical Transactions* to see what Papers may be suggested as falling under this category. [Here Dr. Lodge gave a list of Papers.]

My idea is that amateurs would, as at present, start lines of research, and carry them on until they became unwieldy; but that at that stage, instead of dropping them, or, as we now do, leaving them for the Continent to continue, our own National Laboratory should take them up and incorporate them with the regular work of its staff. At Cardiff I urged this subject in my address. But few of the brilliant assemblage attracted by this city were there present, and so I venture on a few extracts from last year's volume:—"If such an establishment were likely to weaken the sinews of private enterprise and individual research it should be strenuously opposed; but, in my opinion, it would have the opposite effect, by relieving the private worker of much which he can only undertake with great difficulty, sacrifice, and expense. . . . Long continued consecutive observations may be made by a leader of science, as functions may be tabulated by an eminent mathematician; but, if the work can be done almost equally well (some would say better) by a professional observer or computator, how great an economy results! Now all this applies equally to physics. The ohm has been determined with 4-figure, perhaps with 5-figure accuracy; but, think of the list of eminent men to whose severe personal labour we owe this result, and ask if the spoil is worth the cost. Perhaps in this case it is, as a specimen of a well-conducted determination. We must have a few specimens, and our leaders must show us the way to do things. But let us not continue to use them for such purposes much longer. The quest of fifth or sixth decimal is a very legitimate, and may become a very absorbing quest, but there are plenty of the rank and file who can undertake it if properly generaled and led; not as isolated individuals, but as workers in a National Laboratory under a competent head and a governing committee. By this means work far greater in quantity, and in the long run more exact in quality, can be turned out by patient and conscientious labour without much genius, by the gradual improvement of instrumental means, by the skill acquired by practice, and by the steady drudgery of routine. . . . The Meteorological and Magnetic Observatory at Kew (in the inauguration

Digitized by Google

of which this Association took so large a part), is a step, and some useful quantitative work is done there. The new Electrical Standardising Laboratory of the Board of Trade is another and, in some respects, perhaps, a still closer approximation to the kind of thing I advocate But what I want to see is a much larger establishment, erected on the most suitable site, limited by no specialty of aim, nor by the demands of the commercial world, furnished with all appropriate appliances to be amended and added to as time goes on and experience grows, and invested with all the dignity and permanence of a national institution : a physical observatory, in fact, precisely comparable with the Greenwich Observatory, and aiming at the very highest quantitative work in all departments of physical science. That the arts would be benefited may be assumed without proof. It is largely the necessity of engineers that hasi nspired the amount of accuracy in electrical matters already attained. The work and appliances of the mechanical engineer eclipse the present achievements of the physicist in point of accuracy, and it is by the aid of the mechanician and optician that precision even in astronomy has reached so high a stage. There is no reason why physical determinations should be conducted in an amateur fashion, with comparatively imperfect instruments, as at present they mostly are. Discoveries lie along the path of extreme accuracy, and they will turn up in the most unexpected way. . . . . In a national observatory accuracy should be the one great end—the utmost accuracy in every determination that is decided on and made. Only one thing should be more thought of than the fifth significant figure, and that is the sixth. The consequences flowing from the result may safely be left ; such as are not obvious at once will distil themselves out in time. And the great army of outside physicists, assured of the good work being done at headquarters, will (to speak again in astronomical parable) cease from peddling with taking transits or altitudes, and will be free to discover comets, to invent the spectroscope, to watch solar phenomena, to chemically analyse the stars, to devise celestial photography, and to elaborate still more celestial theories, all of which novelties may in their maturity be handed over to the National Observatory, to be henceforth incorporated with and made part of its routine life ; leaving the advance guard and skirmishers free to explore fresh territory, secure in the knowledge that what they have acquired will be properly surveyed, mapped and utilised without further attention from them. . . . . I have spoken of the work of the National Laboratory as devoted to accuracy. It is hardly necessary to say that the laboratory will be also the natural custodian of our standards, in a state fit for use and for comparison with copies sent to be certified. Else, perhaps, some day our standard ohm may be buried in a brick wall at Westminster, and no one living may be able to recall precisely where it is. But in addition to these main functions there is that other : the undertaking of secular experiments on the properties of materials – the elasticity of metals, for instance ; the effect of time on molecular arrangement ; the influence of long exposure to light, or to heat, or to mechanical vibration, or to other physical agents. Does the permeability of soft iron decay with age, by reason of the gradual cessation of its amperian currents ? Do gases cool themselves when adiabatically preserved, by reason of imperfect elasticity or too many degrees of freedom of their molecules ? Unlikely, but not impossible. Do thermo-electric properties alter with time ? And a multitude of other experiments which appear specially applicable to substances in the solid state—a state which is more complicated, and has been less investigated, than either the liquid or the gaseous, a state in which time and past history play an important part. Upon whichever of these long researches we may decide to enter, a national laboratory, with permanent traditions and a continuous life, is undoubtedly the only appropriate place. At such a place as Glasgow the exceptional magnitude of a present occupant may, indeed, inspire sufficient piety in a successor to secure the continuance of what has been there begun ; but in most college laboratories, under conditions of migration, interregnum, and a new *régime*, continuity of investigation is hopeless. I have, at any rate, said enough to indicate the kind of work for which the establishment of a well-furnished laboratory, with fully equipped staff, is desirable; and I do not think that we, as a nation, shall be taking our proper share of the highest scientific work of the world until such an institution is started on its career."

* Mr. R. T. GLAZEBROOK : I presume that I have been asked to speak to you on what Dr. Lodge has so carefully brought before us mainly because it is my privilege to be very closely connected with that laboratory in which, he has been kind enough to say, very much work that would naturally be undertaken by a National Standardising Laboratory has been done during the past few years. Thanks to Lord Rayleigh and that unequalled series of investigations he conducted, the name of the Cavendish Laboratory will ever be inseparably connected with electrical standards and their accurate determination. He has left it to us who are now at the laboratory still connected with the place, to endeavour to carry on the work which he commenced there, and to maintain the high traditions he established. Dr. Lodge has told us so clearly and so plainly what are the main pieces of work that might at present be undertaken by such a laboratory, that there is really not very much for me to say. At the same time it may be interesting if I call attention to some few points of detail of which I have had some practical experience in the last few years —points of detail connected with experiments which might equally well have gone on in some large National Laboratory. Suppose we take as an instance the important question to which Dr. Lodge has referred, of electrical units. As you all know, practically up to the present the old B.A. units of this Association have been for practical purposes the national standards of electrical resistance. Now, in connection with these standards of resistance there are two pieces of important work, both of which, in my mind, might be and ought to be performed by some large national establishment. There is, first of all, the testing of coils and issuing of certificates of resistance, and of other electrical standards, E.M.F. or current. For that there is a great and increasing demand. I feel sure that it would be desirable and useful if the number of coils tested were far larger than any I could undertake to deal with. Coils do come down to me in very large numbers at Cambridge ; but I am so much engaged in other work that this work of testing resistance coils or standards can only be carried on at odd moments, a fact which must at times lead to considerable inconvenience and difficulty. It would be otherwise with a National Laboratory. But that is not by any means all or the most important part of the work which would be carried out in such an establishment. It is desirable, in fact of the greatest importance, that the standards we have here should be identical with those which are used in other countries. It is important that we should feel certain that no changes of a secular nature or otherwise are going on in the standards that we adopt. As you are aware from the reports of the Electrical Standards Committee from time to time that investigation is, to a certain extent, carried out. But it wants far more frequent work, far more continuous observation than I can give to it to make quite sure whether there are changes, and what those changes are. It needs also that our standards should be carefully compared with those of other countries. I have had the privilege—thanks to my position as secretary of the Standards Committee—of comparing my resistance standards and standards of E.M.F. with those in use in France, copies of which were sent to me by M. Benoit. But these should have been sent, to my mind, to a National Laboratory, and not to a private individual. I have recently had the pleasure of working with Dr. Lindeck in observations of a similar character. But work like that should have gone on in some National Laboratory, and not have been merely the work of a private person like myself. What I have said with regard to resistance coils applies equally to all other standards. At the Cavendish Laboratory there are standard condensers. They, again, should receive frequent investigation, and in addition to that they need to be in a place where they would be readily and easily accessible to British and foreign physicists. The same remark applies, of course, to all other electrical standards whatever. We hope that the new Laboratory of the Board of Trade, which is being fitted up so carefully at present by Major Cardew, will in part meet the want. But I feel sure that Major Cardew would agree with me, if he were here, that that laboratory is not on anything like a sufficiently large scale to do all, or anything like all, that is required. I have been speaking up to the present about electrical questions, because they are questions with which I have been most intimately connected. But remarks of a similar nature may be made with regard to other physical questions. What would be the position of engineering without the researches of Regnault ? Take again the work, for instance, being done at present in Paris, at the Bureau International. We in England have done nothing in thermometry that is at all comparable with what has been done there by our guest M. Guilleaume. Or consider again secular experiments. As Dr. Lodge has told us, the experiments on the elasticity of wires which Sir William Thomson started in Glasgow will go on long after Lord Kelvin has ceased to be professor there. But that is an exceptional case. I remember an incident in point which concerns myself. When I first commenced work at the Cavendish Laboratory I had the high privilege of being a pupil of Clerk Maxwell. At his suggestion I was anxious to make some observations on the growth of crystals and the optical properties that they might acquire under certain conditions. I went to Maxwell, and discussed with him what I wished to do ; but he said, "You will have to watch those crystals growing for five or six years." I was a young man, and I wanted to write a dissertation for an examination. What was I to do ? The work remained undone. Dr. von Helmholtz is the President of an institution similar to that we have in mind, established first at the expense of Dr. Werner Siemens, and maintained now by the German Government. I trust he will tell us something of the methods of the institution. I have a Paper here giving an account of the results achieved by the institution in the first three years of its existence from 1887 to 1890. It covers a very wide field of research. I need not go through it in detail. The number of assistants in that laboratory, I believe, is nearly 70. and the annual expenditure is a very large sum indeed. Electricity, heat, light and sound are dealt with, and dealt with in a way which to us here in England is amazing. Those of us who have had the opportunity in private conversation of discussing this matter, either with Prof. von Helmholtz himself or his assistants, well know the great value of the work done. I certainly can assure those great German scientists that I have learnt a great deal from their important work. Allow me then, in conclusion, to ask Dr. von Helmholtz to explain to us why it was that such men as Dr. von Werner Siemens and himself considered it a matter of national importance that Germany should have such a laboratory ; what are the methods and principles on which it is conducted ; what are the aims he has set before himself for that laboratory to achieve, and how at present those aims are being carried out.

Prof. VON HELMHOLTZ said it was not necessary that he should speak on the general aspect of the question. It would be sufficient if he gave a short report of the history of the German institution. It happened that at a certain period they had not mechanicians enough to do the work which was needed for several practical and scientific purposes, which depended on the perfect development of electrotechnics. Messrs. Siemens and Halske had swallowed up nearly all their able young mechanicians. There were some very able mechanicians left, but the masters of workshops had no assistants, and, therefore, they complained that they could not produce as many telescopes and measuring instruments as were wanted for the general staff, and the Navy, and so on. Therefore, it was thought necessary by the Government of Prussia that some steps should be taken to assist mechanicians in their work and to make researches which would be of assistance to them. This was the beginning ; but nearly at the same time came the question of electrical units. It was felt that there ought to be a place where electrical standards could be controlled, and where tests could be conducted and the standards of other nations compared. It was Prussia which first undertook this task. Prussia assisted in the building of the great melting stove of Prof. Abbé, the German optician, and Mr. Zeiss

Digitized by Google

who was a renowned constructor of microscopes. They had arranged a peculiar melting stove for glass, where they began the preparation of glass for optical purposes. This went on very satisfactorily, and afterwards came other questions concerning glass, for instance about glass used for thermometers, and also the glass used by chemists, because it came out that the glass which was easily melted and easily warped was not sufficiently hard; it dissolved very easily, the surface was altered, and many things could not be made with the glass so treated. It was also proved that in thermometers the stability of the freezing point depended largely on the sort of glass used. There were some glasses which after being heated to 100deg. were a whole degree wrong, whilst there existed glasses where this difference was only one-tenth of a degree. He thought for mercurial thermometers this was the greatest source of insecurity, and if they could get rid of that circumstance and diminish the extent of difference they would get far better measurers of temperature. Therefore the first end was to get the Government to assist the art of mechanics. When they came to consider the question of electrical units it was clear that the scientific part must be combined with the practical part of the institution. This was done, and they now had two large buildings; one was not yet finished, but when it was they would have a complete observatory for scientific purposes. The plan was that this observatory for physics should be purely of a scientific nature, as were observatories for astronomy; that was to say, that there should be no instruction—at least, no systematic teaching; in fact, the directors and officers were to be entirely free from the duty of teaching. The laboratories for natural science had developed very rapidly in Germany, yet at every fresh trial it was found that they were not sufficiently numerous. He had himself built in the course of his life the Geological Laboratory and afterwards a little Physiological Laboratory. When he went to Berlin, there was at first a very small laboratory arranged in the University Building. A splendid laboratory was afterwards built, which was separate from the University. This they found to be too small when it came into practice; they were always wanting improvements, and so it was repeatedly enlarged He had guided those laboratories for a very long period. The Professor who now had charge of them was also occupied in teaching; he had to go every day for one or two hours to the laboratory and speak with the different students and counsel them, and ask them how they got on. Very often he (von Helmholtz) had been obliged to make mathematical investigations for himself privately at home, or aided by students. Therefore his time had been very largely taken up, and he was completely separated from all experimental researches. He could only undertake such experiments as were necessarily not of long duration and required looking after for only a quarter of an hour or so every day. Then the number of instruments in such a laboratory was, of course, limited; it was difficult to keep them back from the students, and as instruments which were used by many people, sometimes people not well instructed, must suffer from such usage, they could never be sure that they were in sufficiently good order to serve for delicate experiments, and it was always necessary to begin anew to find whether the instrument was right before proceeding with an investigation. If a man wished to make delicate experiments and measurements it was needful that he should have the instruments to himself, and that nobody else should be allowed to use the same instruments. A student in these institutions which were used principally for instruction could go on with fundamental scientific researches in the way which was probably the best possible for them; and undoubtedly, and in spite of hindrances, a great deal of scientific research had been carried out in the German universities, and a great many important results had been brought out. But there were some kinds of investigations which could not be done in that way. They could not hope that amateurs, even if they were quite independent in their pecuniary means and in regard to locality and time, would go on with fatiguing and often monotonous investigations for the purpose of discovering even important results. Therefore, they came to the conclusion that it was necessary for some fundamental investigations to be pursued in another way with the aid of Government. It was the Prussian Government which first undertook the work, but it soon became clear that it could not be confined to Prussia alone, and that it was necessary to spread the thing out over the whole of Germany. Therefore, the Empire built and endowed the new institution some four years ago. There were two subdivisions of the institution, one scientific and the other practical, because there were some practical questions which it was important to take into consideration. With regard to this technical and practical grant, they had first a great amount of work with thermometers. He (the speaker) had never thought that such a quantity of thermometers were in use. They began with 20,000 thermometers. After a while the Grand Duke of Weimar established a similar institute at Zurich, where a great number of glass-blowers lived in a little village, and there they had about 30,000 medical thermometers every year to test; every thermometer was stamped and numbered, and a certificate was given for it. The number tested in Berlin was not diminished, but rather augmented, in consequence. They were at present testing a large number of chemical thermometers, which were used for higher temperatures, and in which, by bringing compressed nitrogen into the upper part of the thermometer, it was possible to get to nearly 500deg., the mercury by the compression of the nitrogen being enabled to be used in the thermometer until the glass part of the thermometer began to soften and to melt. In the practical division they had also control of the standards of resistance and current, voltmeters, and galvanometers, which were in practical use. They were not very perfect yet, because they all depended on the demagnetisation of iron; but they had found means of getting sufficiently accurate indications for practical use with those instruments. They were now working at new experiments as to the use of indicators on steam engines. A great deal of attention, too, had been given to photometry for the gas and electric lighting companies. There were many different opinions as to the best unit of light, and they had not used the normal English candle, which was not very accurate or reliable, nor the French carcel, They had tried to get a chemically-covered substance with which they could get to a certain limit, and obtain a uniform amount of light at all points; but it was found that the air in which the candle burnt, and the meteorological conditions had a great influence on the amount of light. In some kinds of weather the light was very irregular, and varied as much as 5 per cent. They had made their comparisons always with electric glow-lamps. It came out that the current must be measured to the tenth part if they wanted to be certain that the light emitted by the wire was certain to one-thousandth. They were still pursuing that investigation. As for the method of M. Violle in Paris, they found it too difficult to melt down a great quantity of platinum, so that the platinum surface was quite pure. The slightest degree of impurity, even a little dust spread over the surface of the molten platinum, altered the whole determination; and then the definition of that unit of light depended upon observations which must be made at the moment when the platinum became solidified and it was extremely difficult to make a definite measurement—there was not time. Some good results, however, had been achieved by this method, in a way proposed by Dr. Werner Siemens, using thin strips of platinum, which were melted by electric current; indeed, it really seemed that used in that way it was a better standard of light than any hitherto employed. Switzerland and Austria were now paying more attention to the importance of a system of schools for mechanical and engineering purposes, and he was pleased to hear that similar schools were also spreading in England In the scientific part of their institution in Berlin they had proceeded very carefully with researches on the value of electrical standards. They were obliged at first for technical purposes to go on as swiftly as possible and they had made proposals to the German Government which were very similar to those made by the British Association to the British Government, differing only on some special points. Then they had begun a great work which should prove of fundamental importance in thermo-dynamics. In making those investigations it became quite clear that many of the calculations of Regnault were not very accurate; a great many errors in calculation had been found already. To carry out this investigation they had subdivided the work as carefully as possible, so that many determinations might proceed simultaneously. This was a great and an extensive work, which could, of course, only proceed very slowly. Years must pass before they could reach perfection.

* Lord KELVIN: I am sure it is with very great pleasure that the Section has listened to Prof. von Helmholtz. The subject opened by Prof. Lodge in his presidential address to Section A of the British Association last year is really one of national importance. I think, after what we have heard from Dr. von Helmholtz, we need have no hesitation whatever in feeling we have ample ground to go upon to prove the value of such an institution as the Physikalische Reichsanstalt of Berlin. As Prof. Lodge has shown, in a faint and imperfect manner we have done here and done there and in other places some slight things towards the great object which has been realised in Germany. What greatly struck me during the speech to which we have just listened were Prof. von Helmholtz's remarks with regard to thermometers: 20,000 in Berlin, 30,000 in the Thermometric Institute of Weimar! This is really a matter of life and death; it is a matter of life and death to be able to distinguish between a temperature of 98deg. and 98½deg. Fifty years ago with the very best and most expensive opticians, who combined with optical work the sale of thermometers at 15s. or £1, errors of from 1° F. to 1½° F. were found. Our thermometer testing at Kew corrected that state of things about forty years ago. In it the testing of thermometers is practically carried to a very close degree of accuracy; and thermometers so tested can now be purchased at moderate prices from ordinary opticians in this country. I do not know whether it is from Germany that our clinical thermometers are now obtained; but medical men have discovered that the practical use of clinical thermometers is of extreme value. We want to be told what is done in Germany in order that we may be led to increase vastly our resources in this direction. It is not a matter of national jealousy; but it may be properly a matter of national emulation. It is a noble object to prompt the artisan of England to put in as good work, and to have as good scientific direction for his work, as his brethren in Germany. After what we have heard of what the Duke of Weimar is doing for promoting the usefulness of the work of the large number of glass-blowing artisans in his principality, we must feel that it would be well for the Government of this great United Kingdom to do all it possibly can to render the work of the artisans of England, Ireland and Scotland useful to this country. The grand success of the Physikalische Reichsanstalt may be judged to some extent here by the record put before us by Prof. von Helmholtz. Such a proved success may be followed by a country like England with very great profit indeed. One thing Prof. von Helmholtz did not mention was the discovery in the Anstalt of a metal whose temperature coefficient in respect of electrical resistance is practically nil; that is to say, a metal whose electrical resistance does not change with temperature. This is just the thing that we have been wanting for twenty or thirty years. It is of the greatest importance in scientific experiments, and also in connection with the measuring instruments of practical electric lighting, to have a metal whose electrical resistance does not vary with temperature; and after what has been done, what is now wanted is to find a metal of good quality and substance whose resistance shall diminish as temperature is increased. We want something to produce the opposite effect to that with which we are familiar. The resistance of carbon diminishes as temperature increases; but its behaviour is not very constant. Until within the last year or so nothing different was known of metals from the fact that elevation of temperature had the effect of increasing resistance. The Physikalische Anstalt had not been in existence two years before this valuable metal was discovered.

Prof. VON HELMHOLTZ: The discovery of a metal whose resistance diminished with temperature was made by an American engineer.

Prof. AYRTON: By an Englishman—Weston.

Digitized by Google

Lord KELVIN: That serves but to intensify the position I wished to take, whether the discovery was made by an Anglo-American, an American Englishman, or an Englishman in America It is not gratifying to national pride to know that these discoveries were not made in this country.

The PRESIDENT: We ought to hear the opinions of as many of those present as possible. Dr. Gould is connected, to some extent, with the subject, and we should be pleased to hear him.

Dr. GOULD: I have very little to say on the subject; but as I have the honour to be a member of the International Committee, I would use this opportunity to mention one point. Mr. Glazebrook spoke of what the French have done in thermometry. I would remind him that the work to which he alluded is being carried out by an International Committee, on which England is represented.

Prof. RÜCKER: I understand that it is desirable that those who speak should be as brief as possible, and I will only refer to two points of which I have practical knowledge. In the first place, with regard to thermometry, as a member of the Kew Committee I may say that a short time ago we wished that our mercurial standards should be compared as closely as possible with the hydrogen thermometer, and it was not altogether satisfactory that we had to send our instruments across the channel to Paris in order that the comparison might be made. As a matter of fact—and this shows the risks to which they are liable in transmission—one of the thermometers was broken. It is quite evident that we ought to have in England some place where measurements of that kind can be made. Of course, the Kew Committee would be willing to compare gas and mercurial thermometers; but two things are wanted—money and room. Then, again, with regard to another matter to which reference has been made—photometry. As those present well know, we have for years been giving great attention to determining the unit of light, and we owe much, in fact nearly everything, to one of the officers of this Association, Mr. Vernon Harcourt. A good instance of the way in which matters of this kind are dealt with in England is the fact that some twelve years ago a Board of Trade committee investigated and reported strongly in favour of Vernon Harcourt's pentane unit: nothing has yet been done, and the question is now remitted to another Board of Trade committee of which I have the honour to be a member, yet I cannot but feel that the enquiry might be best worked out by a permanent staff attached to a Government institution. Those who know—as most here do—the engagements with which most of our time is occupied well know how difficult it is, for instance, for a man like Mr. Vernon Harcourt to come up to London to carry out experimental researches. As a matter of fact, he had to give up half his Long Vacation to do it, and it has been extremely difficult for the rest of us to fit in with his time. Naturally the work is not done so quickly, or with that thoroughness, which would be the case if it were in the hands of a Government institution. As far, therefore, as everything connected with the standards is concerned I think there is very little doubt that it would be extremely advantageous if a national institution could be started, largely in connection with the Royal Society, for the care and comparison of standards. There is one other point. Although it is quite right that such an institution should carry out such researches as its directors might think desirable for the progress of science, nevertheless I do hope nothing will be done in this direction to divert the meagre funds at our disposal for the encouragement of individual research. There are certainly cases where individuals carry out important tasks which a corporate body refuses to undertake. I hope, therefore, the Government Grant Fund for research will be allowed to remain as at present, and that the Royal Society will still be able to encourage investigators as much as they now do. I should be extremely sorry to see research and teaching in any way divorced. Both for the sake of the students and of the professors it would be a great pity if scientific men became divided into two groups, those who investigate and those who teach. The experience of Germany, at all events up to the present, shows that there is no serious risk of that disaster. In that country we know that in spite of the success of the great institution which Professor von Helmholtz has described, the universities and colleges do a great amount of original work. While, therefore, we are careful to provide for original research, we must also be careful to keep together research and teaching.

Captain NOBLE: I take it that we are all agreed that the National Physical Laboratory is necessary. Dr. Lodge has laid the whole subject before us; and I fancy none of us, either laymen or professors, doubt the desirability of establishing a Physical Laboratory, and I merely rise to suggest that a resolution be passed by this Section to be forwarded to Government in order that some arrangements may be made for utilising that department of education known as the Science and Art Department at Kensington. There is an impression that that department is not very active with its practical work, that the value of its work is not quite so high as it might possibly be. I may be wrong, but there is that impression; that there is a little time now and then which might be devoted to this particular purpose. That is to say, that some of those gentlemen might be employed in examining the questions which it is so necessary should be examined by a central body; and I would suggest that a resolution to that effect, if it be in order, be prepared and submitted to the meeting, and forwarded to the Government. We might rely upon the support of Lord Kelvin and the learned President of the Association, Sir Archibald Geikie.

The PRESIDENT: It is not usual for the Section to pass any resolution of this kind. We have appointed a Committee, and if the Committee reports it will go its natural course through the Council, and the Government be approached in that way. A resolution would be quite out of order here.

Prof. G. F. FITZGERALD: I would like to say a word as to what has been said with regard to our all being quite agreed that a National Laboratory is desirable. We ought in the first instance to consider carefully whether we can develop our present resources. There are certain institutions which ought to devote themselves to this work a great deal more than they do at present, and if anything is to be done I think it is that a Commission should be appointed to inquire how it is that these present institutions do not do the work they are supposed to do, instead of proposing to start a completely new institution. I only bring this forward because I think it desirable that views of that kind should be expressed. In order to get money from the House of Commons it is necessary to prove that some definite advantage will accrue to some definite class in the community which will be an important class of the community. For instance, in the case of Berlin, as I understand it, it was necessary to provide something required by the Army and Navy. If it can be proved that something like the Physikalische Anstalt is required for the Army and Navy there will not be the least difficulty in persuading the British Government that it is necessary to provide it. But I have not heard that it is required for the Army and Navy or for any serious class. The English people and the House of Commons are not sufficiently educated to understand that the mere advance of scientific work is of value to the community. Until we have persuaded them of that I do do not think it will be worth while for the British Association to ask for anything very definite, because the House of Commons first requires a great deal of education in the necessity for general scientific advance to prove to them that general scientific advance is of importance to the community, and until they learn that it is of very little use for the British Association to press this particular request. As I have said, there are certain institutions which ought to do this at present. The business of a university is research; that is its first business; the second is to teach. They would have money enough if they would not spend more than the proper amount of their funds upon the students and the cripples who go there. The first thing that the House of Commons would do would be to find out whether the money which ought at present to be spent in such work as has been alluded to, is really spent in that way. Something like £600,000 a year is spent in two universities in England, and plenty of money might be got out of that to carry out scientific research, literary research, or anything else, if it were properly spent. But an enormous amount of money is spent there in teaching cripples to run. The first thing which should be done is to petition Parliament to inquire whether the universities spend their money in the way it should be spent, and to try to get that money spent in increasing the scientific and literary work of the country. The only pressing thing standing out at present that requires to be encouraged is this standardising work that is being done in the laboratory at Cambridge. There is now a Board of Trade Committee starting on that work; all that is required is that they should develop their work in that direction, and that money should be spent on that, when the only outstanding work desirable for the good of the country would be being done by a central institution. It is not at all obvious that it is desirable to amalgamate the Board of Trade work with the work done at Kew and at Greenwich; on the contrary, there are a great many advantages in having a number of different institutions carrying on different kinds of work, instead of one enormous institution under an autocratic head, carrying on the whole thing. It is very desirable in some ways that the different things should be kept separate. Another thing could be learnt from Berlin. Who was it started this institution? Werner Siemens—a private individual. Where are all the private individuals with hundreds of thousands, millions, of money, who take example by the Grand Dukes in Germany? Where are the Grand Dukes in this country? I would only reiterate that I do not think the time has come yet for pressing upon the Government to start anything of the kind. The matter requires a great deal more, a great many years more, careful consideration before it is clearly shown that a Physikalische Anstalt, such as that at Berlin, which has been supplemented by others in another part of Germany, is desirable in this country. It would be very much better if universities, with the immense funds at their disposal, or with additional funds given them, to dispose of, if that is necessary, would undertake the work of research required by the country, because it is undoubtedly their business.

Sir GEORGE STOKES: I do not altogether agree with Prof. Fitzgerald that the first work of universities is research, and that teaching is merely something subordinate. My notion is that the first work of a university is to teach. In order that this teaching should be well done it ought to go hand in hand with research; of that there is no doubt at all. But what sort of research? The researches that Prof. Lodge contemplated as what in his opinion ought to be undertaken by a national institution, are not precisely of the kind which would be suited to bringing out the ardour of young students. They want rather to have their enthusiasm excited by something which holds out a prospect of a new discovery, some new advance in knowledge. Of course, a long and laborious series of quantitative measurements are important as conducing to our stock of knowledge; but where the researches are such as go on year after year, they are not of a kind to bring out the enthusiasm of young men. Therefore I think the universities are not the proper places for carrying out those long-continued laborious researches of the kind which Prof. Lodge contemplated. I will just say one word more with regard to what Prof. Fitzgerald said as to private individuals coming forward and furnishing from their own resources—I mean, of course, wealthy individuals—means for carrying on such researches. Now, there again, I think you could hardly expect private individuals to form institutions of that non-ecclesiastic character, if I may call it so, which Prof. Lodge contemplated. But I cannot sit down without reminding Prof. Fitzgerald that the institution at Cambridge, which has already been mentioned in such terms of commendation—I mean the Cavendish Laboratory—was founded by the private liberality of our late Chancellor.

Lord KELVIN: The real primary duty of universities is to teach. Research naturally falls in with teaching, happily for professors and others whose duty it is to teach. But Prof. Fitzgerald seems to forget that the life of a student is three years, and his laboratory life six months. Surely

Digitized by Google

an institution whose primary duty is to teach should make the best of the time it has with its students, and cannot get much of it for research. Certainly research ought to be continued, and must be continued, in University physical laboratories, but I think there is a great want of an institution where graver research than anything that can be done in a student's laboratory may be carried out, and where there should be a greater permanence than is permitted by the fluctuating circumstances of the workers, if not of the conductors, in the universities. Why not private individuals? If any private individual will come forward with £500,000 to endow the nation with a physical laboratory, certainly the gratitude of the world will be accorded to him. But if it is of national importance is it dignified that we should wait for a millionnaire to do it? It is a very poor argument to use to the Government—"If you wait long enough there may be a chance of some millionnaire in this country or in America doing it for us." That it would be desirable to establish such an institution is proved as much by Prof. Fitzgerald's opposing it as by any of the speeches made in favour of it.

Prof. CAREY FOSTER: This question of research and the sort of work which should be done by the National Laboratory seems to me to be a little bit confused. We have had the laboratory advocated for the sake of the benefit to be conferred on industrial operations; but I think beyond that there is a still greater reason in what I may call the advancement of pure scientific knowledge. The idea that such an institution, if established, would be the home of physical research for this country seems to be quite apart from the idea which Prof. Lodge has put before us. It would not supersede research and investigations of private individuals, and university professors and other officials; but it would rather support and assist them. The work which, as I understand, it is wished to take up, is determinations of the utmost accuracy of numerical constants, work which could scarcely be done by individuals, in consequence not only of the expense involved in it, but the enormous time required, the continuity of work and observation necessary for great accuracy. Very often what seems to be the simplest possible operation is almost inconceivably difficult without quite special knowledge of the subject. I might refer to one of Prof. Fitzgerald's propositions with regard to private munificence. Sir George Stokes has already reminded us that the one chief place where work of the kind is carried on, the Cavendish Laboratory, is due to private munificence, and I may add that the only place in this country which approaches the same end, the Kew Observatory, is also privately endowed.

Prof. AYRTON: I am afraid my ideas are not very clear on the subject. As to the function of a university, to a great extent I agree with what Prof. Fitzgerald has said. I also agree with what Sir George Stokes and Lord Kelvin have said. I think the proper function of a university is a combination of the two—is to teach by or through research; and that is why I think the teaching given by a professor at a university should differ from the teaching given by a schoolmaster. In one case the schoolmaster is teaching what is already known, but what the student at a university should be taught is the way to find out what is not known. I can quite see the sort of experiments Prof. Lodge has referred to; the finding of the fifth or sixth decimal cannot be carried out without great difficulty at the ordinary university. On the other hand, it is most improbable that the British Government would give any money whatever for the purpose of bringing out the sixth decimal; they have absolutely no interest in such matters. There is need for far greater facility for standardising; that is a far different thing altogether. A large portion of the work carried out by Reichanstalt is the certifying of Clark cells, electrical standards, and other similar work. Now we already have not merely a committee who advise the Board of Trade, but there actually is a Government Standardising Laboratory in Parliament-street at the present moment, and if 20,000 or 30,000 galvanometers were brought there no doubt it would be enlarged to do that large amount of work. I fancy if the English population were to send 20,000 or 30,000 thermometers a year to be standardised in the same way the facilities at Kew would be increased; there would be no difficulty whatever in getting the Government to take up standardising. There had been no great difficulty in getting the Board of Trade to start that Electrical Standardising Laboratory. But when that proposal was first brought forward at the Institution of Electrical Engineers, I ventured to say what Prof. Fitzgerald has said far more eloquently to-day. I may mention that the proposal brought forward was that there should be a Government Electrical Standardising Laboratory for a different kind of work, one for standardising instruments and the other for the carrying out of electrical research; and I pointed out that the latter was really one of the functions of a university. No doubt there is great need of facilities for standardising instruments, and that we have already obtained, and it will undoubtedly be very much enlarged if there is any need. There remains this other need of getting out the fourth or fifth place. I do not see at all why that is to be carried out. It seems to me, as has already been said, that it is quite impossible to get the English Government to give money for secular researches, and I fear for the present all we can hope to do is to largely increase our facilities for standardising commercial instruments, leaving to universities and to private people both researches for the advancement of knowledge and also for getting greater accuracy in our physical constants. One thing has not been suggested which I do think requires consideration; that is, the too much teaching which is demanded of professors. Say, for instance, the reader of the Paper, Dr. Lodge, who, as everyone knows, has done most magnificent work in a particular line of research in connection with electro-magnetic radiation; but quite recently the authorities of the University at Liverpool have decided that Dr. Lodge, with assistance, ought to teach electrical engineering. I do not mean to say that Dr. Lodge is not able to teach that, but he is able to do very much better work, something else that others who can teach electrical engineering cannot do. The carrying out of Prof. Lodge's suggestion of starting a National Laboratory would, I fear, bring about that which I deplore so much—that professors would be told it would be their duty to teach all sorts of things, and not pursue research. What we ought to aim at is to give greater freedom to professors and others in the matter of original work.

* Prof. LODGE: I hope this matter will not be undertaken by an individual; I think it is really an Imperial matter. There is so much for private munificence to do in local matters, starting colleges, and endowing local institutions; but this is Imperial work. Much has been said of the difficulty of approaching Government. It cannot be said that the First Lord of the Treasury is at all averse to scientific ideas; and no doubt there are other members of the late, or present, Government, whichever it is, who would be in the same position. Our position is not to see difficulties in the ignorance of the House of Commons, but to try and teach them the proper thing; we should not feel these difficulties too strongly. With regard to teaching, Prof. Rücker said teaching should not be divorced from research. But let him just remember how many an English professor gets taught? He goes to Germany and in some such place as the Reichanstalt under von Helmholtz becomes for a time one of his 70 assistants there. Is not that teaching, and teaching of the right sort?

The PRESIDENT: Before concluding the discussion, I am rather anxious that the principal points which that discussion seems to me to have brought out should not be lost sight of. Some of the remarks that have been made, especially with regard to the function of the university, seem to me a little beside the question, to have nothing to do with the question at hand, and I am afraid they may have rather obscured the main points at issue. There are two or three points clearly shown by the statement of Prof. von Helmholtz, and which it would be well for the members of the Section to remember. It is generally acknowledged, even by those who are opposed to the establishment of a laboratory, that a place to standardise instruments is necessary. Now I hold, and I think it has been shown that no confidence can be reposed in a place where only the standardising of instruments is carried on, and where no research of the highest kind is pursued at the same time. That is the most important matter brought out by Prof. von Helmholtz. An instance has come to my notice. It has been said how important the Reichanstalt has been in thermometry in finding out the right kind of glass. Kew has been testing thermometers with a view of ascertaining whether it is possible to get glass here which will do equally well. I have thermometers in my pocket which Joule made in 1840. That glass is as good as any that can be made now. The art of making glass has been lost. The glass made now is not of the same nature as that made in this country fifty years ago. I believe if we could get back to the glass used at that time we should have thermometers equally as good as those. If such work had been carried on at Kew, together with the testing of thermometers to a greater extent, our instrument makers would be in the position of making thermometers of a very high order. There is this other point clear also from the remarks made, the enormous importance of research work of this kind to the artisan, to the instrument maker. That has, I think, been clearly shown, and I will not take up the time of the Section in proving the point. It has been suggested that Prof. Lodge has asked for a new departure. It seems to me, however, that all that is asked for is that physics should have what astronomy, pure astronomy, has had for a very long time. It is all very well to say that Greenwich is necessary to navigation. If you were to take away everything at Greenwich that has no direct bearing on navigation you would have very little left. The country is proud of Greenwich, but it does research work chiefly, and the actual work necessary for the Navy is really a small matter. Therefore, what is now sought is not a new departure, but really an extension to another branch of science of that which has grown to be necessary in the oldest science of all—astronomy. I am sure that whatever may come of this discussion it has cleared up our ideas on the subject, and I ask you to thank Prof. Lodge very heartily for again opening up this subject, and to accord a special vote of thanks to Prof. von Helmholtz for the information he has given us regarding the Physikalische Reichanstalt.

CORRESPONDENCE.

BRITISH ASSOCIATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 12th August you state that the reading of two Papers on Transformers at the British Association was accompanied with a considerable drop in the attendance; but you do not mention that this drop was really caused by the absence of "feeders."

To retain their presence during the lunch hour is practically impossible. And without feeders, as every electrician knows, a drop is inevitable.

Further, so many Papers were put down to be read that the alternation from subject to subject was necessarily very rapid. Now, as was shown in one of the two communications in question, the greater the frequency the greater the drop. In fact, towards the end of the meeting, the rate of alternation became so high that in Papers rather than in people was the drop most apparent.—I am, Sir, &c.,

Switzerland, August 29th. W. E. AYRTON.

THE DIMENSIONS OF PHYSICAL QUANTITIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The dimensional expressions [L], [M], [T], &c., are defined in two ways, viz., as concrete units, and as change ratios; and the point at issue is as to the merits of the two systems founded on these two methods of definition.

When, then, Prof. Rücker states that the equation [L] = 2 is "false by definition of the symbol [L]," he affords us an unusually glaring instance of the fallacy *petetio principii*.

Of course, if [L] is a length, [L] = 2 is absurd; if [L] is a change-ratio, to say that [L] = 2 is merely a concise way of saying that we choose to halve our unit of length, and is neither absurd nor false by Fourier's rule, which, indeed, has nothing to do with it.

It is kind of Prof. Rücker to explain to me the origin of my difficulties; but on this subject I have none. I avoid them all by adopting the change-ratio definition of the dimensional expressions.—Yours, &c., W. M. M.

LEGAL INTELLIGENCE.

At a sitting of the Consistory Court of London, held on Monday last in St. Paul's Cathedral, before Dr. Tristram, Q.C., Chancellor of the Diocese of London, an application was made for a faculty to authorise the construction by the City of London Electric Lighting Company of a transforming chamber in the churchyard of St. Benet Fink, Royal Exchange-avenue. Mr. Arnold Statham appeared in support of the application. The churchyard was vested in the Corporation of London by the Act 5 and 6 Vic., cap 101. The rector and churchwardens had consented to the transforming chamber being constructed in it subject to the leave of this Court having been first obtained.—The Chancellor reserved judgment.

This was also the result of an application for a faculty to authorise the construction, by the City of London Electric Lighting Company, of a transforming chamber in the churchyard of St. Nicholas Cole-Abbey.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—We would remind our readers that 11 a.m. Thursday next, the 8th inst., is the latest time for depositing with the Chairman of the Gas Committee of Leicester tenders for lighting the Corporation area of supply. Particulars appear in our advertisement columns.

——— The Urban Sanitary Authority of Portsmouth invite tenders for the erection of an electric lighting station in the Gunwharf-road, Portsmouth. Tenders must be delivered to the town clerk by 6 p.m. on the 26th inst.

——— The Corporation of Bradford require tenders for the supply and fixing of new roofs, floors, and other works. Particulars of Mr. W. T. McGowen, town clerk, Town Hall, Bradford. Tenders to town clerk by the 7th inst.

PLANT FOR SALE.—Our advertisement columns contain a notification of the sale by private treaty of the lease of the premises lately occupied by Mr. J. Collins at Hove, together with the modern stock of electrical plant. Full particulars may be obtained of Messrs. Ward and Wilding, chartered accountants, Bloomsbury Mansions, Hart-street, London, and 8, North-street, Brighton; or of Messrs. Bullock and Sadler, 33, Queen's-road, Brighton.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—This Company announce that on and after the 1st instant a new station will be opened for the reception and delivery of transatlantic telegrams at 39, Mark-lane, E.C., and that this station will be opened day and night, Sundays included. In future the Company's station at 34, Throgmorton-street, E.C., will be open from 9 a.m. to 8 p.m. from Monday to Friday, and from 9 a.m. to 6 p.m. on Saturday, but will be closed on Sunday.

BANKRUPTCY.—A receiving order was issued on the 27th ult. against the estate of Messrs. Cox, Robinson, and Co., carrying on business as electrical engineers at 8, Strand-street, Liverpool.

——— The following are the principal creditors against the estate of James Collins, lately carrying on business as an electrical engineer at 80, Church-road, Hove:—

	£	s.	d.
(?) Electric Light Company, London	50	7	5
Emanuel and Son, London	38	14	0
Gent and Co., Leicester	15	7	8
Gulcher (New) Electric Light and Power Company (Limited), Battersea	100	0	0
India-rubber, Gutta-percha and Telegraph Works Company (Limited), London	20	9	5
London Electric Wire Company (Limited), London	12	10	11
Robey and Co. (Limited), Lincoln	89	0	0
Verity and Sons, London	131	8	5
Woodhouse and Rawson United (Limited), London	89	3	10

The total liabilities are set down at £2,158, and the assets, after deducting preferential claims, at £949.

MESSRS. DRAKE AND GORHAM.—We have received a copy of this firm's latest illustrated catalogue, which contains full particulars with regard to their well-known specialities such as ring contact switches, excess indicators, battery testers, Cardew earthing devices and voltmeters, &c., &c.

CLUB LIGHTING.—The Conservative Club, St. James'-street, is undergoing redecoration, and it has been decided to introduce the electric light. It is estimated that about 400 lights will be required, and the work will be done under the superintendence of Mr. A. A. Campbell Swinton.

DISSOLUTION OF PARTNERSHIP.—The partnership is dissolved between Messrs. Simpson and Hill, carrying on business as manufacturers of electrical, optical, and scientific apparatus at 2, Aldersgate-buildings, E.C. Debts will be paid by Henry Hill.

COMPANIES' MEETINGS.

The City of London Electric Lighting Company (Limited).

The second annual general meeting of the City of London Electric Lighting Company (Limited) was held yesterday at Winchester House, Old Broad-street, Sir David L. Salomons, Bart., presiding.

The SECRETARY (Mr. J. Cecil Bull) read the notice convening the meeting. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: On the last occasion that I had the honour to appear before you with a considerable amount of difficulty we waylaid one shareholder in the passage and got him for our audience. I am pleased to see to-day that you are so many in this room. It shows, at any rate, that if, before, you had every confidence in your Board carrying out your work, now your interest has wakened up, and I trust that your confidence is not less in consequence. I propose now, before moving the adoption of this report, to place before you all that has taken place since the last meeting. On that occasion I gave you a history of the formation of the Company up to that time; I will now continue it up to the present day. The applications for shares then amounted to £300,000, which we considered very good; £100,000 remained to be applied for. This, I am glad to say, is now not only all applied for, but will be employed for your work in a very short space of time. The whole of the ordinary share capital has, therefore, been taken up, and the money will have been spent probably in another month or six weeks. It is, therefore, the intention of your Board to issue some preference stock. It is intended at present, and I have no doubt the intention will be carried out, to issue half the preference stock—£200,000—at 6 per cent.; and to give the shareholders the first chance of obtaining it. You will find, I think, that this 6 per cent. is very well secured, and may be regarded as a first-class property when in your hands. I think myself, and I believe the Board will in a great measure agree with me, that before very long—not to be too hopeful, say within twelve months—that we shall be in a position to pay a dividend to the ordinary shareholders. Matters have now begun to mend. The first difficulties that had to be encountered have been met, and very satisfactorily met. The stations are working now, not at a loss, but at a small profit, which will grow as the machinery comes into work. At present we are not working a full load. As that is put on the money will come in, and every penny will give a profit, for the standing charges will not increase in proportion. It is merely the coal bill which goes up, and that is comparatively small after the staff has been paid and the office expenses and various other matters have been met. We have at the present time a site and buildings and other works which must exist, and all these bring in no return. That is a necessity of all companies and undertakings of this nature. All the money that we now expend will be fruitful in the future. There are one or two points in the report that I would like to call your attention to. On page 3 there are the words: "From calculations based on the lamps already connected to the Company's mains, it appears that the consumption of current per lamp installed in city offices, shops, &c., will be much greater than was anticipated." It was pointed out to me by a gentleman that, perhaps, that might be taken to mean that consumers of electric energy in the City were paying more than in other districts, or in some way were at a disadvantage. But that is not so. In the West End, where there are drawing rooms, and people give parties occasionally and are away for the greater part of the year, and in shops, where they are only alight for a very short time, you will find that the number of lamps installed is perhaps four times the number in general use. The average earnings of a lamp would in that case be only one-fourth of its capacity. In the City matters are different. Of the lamps installed, probably almost all are in use when the weather is dark, and consequently the return per lamp is greater. I should also mention another point. That is the matter of not stinting money in putting up your fittings. It is a loss in the long run to do so. It is much better to have your work thoroughly well done, so that no trouble will ensue with the light. Nothing has brought a bad name upon electric lighting quicker in many places than the fact that the fittings have been bad. With water, gas, and drainage every precaution is taken, but with electric lighting the general rule is that the man who will give the lowest tender is given the job, and the result, in most cases, is not satisfactory. I have no doubt you have been round the City and seen the beautiful illumination now visible at night and you will see it better by-and-bye, when the days grow short. One thing that must strike you is that all that is in sight is thoroughly well

Digitized by Google

done and the work out of sight is just as good. Go even to the works and you will find there, though the place is now in great confusion in consequence of the presence of builders and the erection of machinery, that what has been done and is doing is conducted in a thorough manner. After now nearly every pound spent will bring a return. Everything which the Company has done has been done thoroughly, not in "gingerbread" style, and it has been the first wish of the Board to give satisfaction to the City authorities and the public. This was not at first appreciated, but by this time it must have become evident to all. The Directors have spared themselves no trouble, nor have they considered their private convenience in carrying out the affairs of the Company. The Board goes into every detail before money is spent, and inquires into the doings of sister companies, in order to gain experience from the success and failure of those gone before them. One circumstance we deeply regret, it is the absence of Mr. Charteris to-day. He has been long ill, but we hope that the time is not far off when he will join us again and assist us in our work. I am pleased to say that all calls are in with the exception of £62. Before sitting down I will give you a few details of our work during this year for your information and for those who are watching our progress. You must remember that when our buildings and their contents are finished, the standing charges will practically be stationary. The variable quantity will be the coal bill, so that if we are able to show a fair result during the next two years success is assured, provided our customers continue to increase as in the past. The lighting of the City is exceptional, as the curves before you show; in fact, they are contrary to the experience of all other companies. We shall require a favourable winter from one point of view, *i.e.*, one abounding in fogs and dark days, in order to learn what the City population require of us. The Board have no desire to be extortionate, and when the shareholders obtain a fair return on the capital they risk, and after due provision for sinking fund, reserve fund, and maintenance, they hope to reduce the price of the current. I know that the Board, with their officers and *employés*, are doing their best to meet the confidence reposed in them by you and the public. They simply ask a little patience and indulgence until the works are completed at the stations and sub-stations. Your Board have not lost sight of a probable demand for energy for motive power which is certain to arise for lifts, running machinery, cranes, advertising purposes, &c., and they have laid down a large reserve of spare ways, to avoid the expense and inconvenience which would arise by opening the streets a second time. It may be mentioned that it is proposed to work all cranes, pumps and other machinery at the stations by electro-motive power. It is expected that many markets, railway stations, and other public places will obtain current from us for arc lighting. The rules laid down by the Board of Trade practically rendered this field of lighting impossible for a public lighting Company. The Board, therefore, waited as a deputation upon the Board of Trade, and they were very kindly received by Sir Henry Calcraft and Sir Courtenay Boyle. The result was that our request for a modification of the rules were acceded to, if certain precautions were taken. The details of these precautions have yet to be settled. The most pleasing circumstance connected with the interview is the disposition shown by that Government Department to assist the public in obtaining the prince of modern lights. Any points connected with the report or the accounts I shall be happy to explain, also to reply to any questions you may desire to ask at the close of the proceedings. You will observe that the cost of working the stations is "turning the corner." It is our intention to have the curves before you kept up regularly and photographed yearly, to be sent round with the reports. Much information will be given to you this way, and to scientific men, who are working on the same subject, these results will be invaluable. It is not our desire to have any secrets, but to give you and the world the fullest information. This course will assist the cause of electric lighting more than any other. By the spring it is expected that our stations will be able to supply 78,000 8 c.p. incandescent lamps, in addition to the 700 arc lamps which can be run now. These figures represent totals including reserve. Considering the inclemency of the past winter, and the short time which has elapsed since the starting of this Company, we claim that the amount of work done is beyond precedence, 'beating the record,' as sporting people say. Our present gross earnings exceed £20,000 a year, and this will increase as we are able to meet the demand for current. So far the demand has always exceeded the supply. Although we are distributing energy at this moment under many disadvantages, the total loss of electric energy from station terminals to consumers' terminals does not exceed 26½ per cent. When our dynamos and transformers get their full load—now they only work at half load—a very good result may be expected, showing that our system of distribution is good. All the machinery which has been erected is of good workmanship and sound, and it is satisfactory to learn that the machines now in course of construction will have a capacity 10 per cent. higher than that contracted for continuous work. This is ascertained from tests on similar machines recently completed. These machines were intended for 6,000 8 c.p. lamps. Fogs will no doubt test the efficiency of our installations very severely, yet we have every reason to believe that we shall meet the difficulties with perhaps a little trouble upon the first or second occasion. Probably observations made from elevated points will assist in ascertaining the approach of a fog. The Docks Committee has kindly promised telegraphic communication from the docks when fogs come from that direction. In any event every means will be tried for obtaining notice of a fog coming on by telephonic communication and other means from points around London. To give you a notion of the progress of the street work I may mention that at times as many as 30 miles of tubing were placed underground in a week, and the average for the year has been about 10 miles of way per week. The contracts with the City for arc lighting in main thoroughfares required the laying of trenches in 47,072 yards of streets. On June 30th 43,134 yards were laid and now 45,410 yards, leaving to complete 1,662, which will be finished during the next three or four weeks. Of the work in the lesser streets not compulsory on June 30th, trenches were laid 46,378 yards, or about 26⅓ miles, now 49,412 yards. There has been laid to this date 303 miles of ways. The length of cables drawn in to date is 63¼ miles of high tension, and 22 miles of low tension. On June 30th there were in the streets 184 arc lamps, now there are 334. By the middle of this month all arc lamps under the City contracts will be running, excepting a few delayed for special reasons, such as building operations, reconstruction of refuges, &c., our last day really being November 5th, so that we are unlike most contractors in being ready before our time. On June 30th there were 11,800 8-c.p. glow lamps on 6,735 yards of main, giving a lamp density of two lamps per yard of main. If this density were to hold good throughout the area of the street work now ready to receive, mains would give 190,000. In Lombard-street the density is six lamps per yard, and Cornhill is very nearly the same. Our two stations, since August 1st, have been supplying current continuously day and night. In placing before you so many facts and details my wish has been to render you a full account of the work in which you are embarking your capital, and to show you that those in whom you have placed so much confidence are not going to sleep or to allow their energies to rust. I have now to move:—

"*That the Directors' report and the statement of the accounts to June 30, 1892, be and the same are hereby received and adopted.*"

Mr. PURCELL seconded the motion, which was carried unanimously.

Mr. PURCELL moved that Messrs. W. H. Pannell and Co. be re-elected as auditors, with a remuneration of 100 guineas.

Mr. KELMAN seconded the motion, which was unanimously adopted.

Mr. CLARK, in moving a vote of thanks to the Chairman and Board of Directors, took occasion to express his sense of the admirable manner in which they had performed their difficult duties, and stated that though his ten years' connection with the Brush Company had not been financially successful, he had every confidence in the future of electric lighting.

Mr. E. K. SMART seconded the vote of thanks, which was accorded unanimously.

The CHAIRMAN having replied, the meeting ended.

NEW COMPANIES, STATUTORY RETURNS, &c

KENNEDY STORAGE BATTERY COMPANY (LIMITED).—This Company was registered on August 24th, with a capital of £100,000, in £1 shares, to enter into and carry into effect an agreement between Patrick Kennedy and Charles J. Diss and the Company to acquire certain letters patent, inventions, secret processes, &c., relating to storage batteries, and to carry on the business of electricians, electrical contractors, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat, sound, motive power, or otherwise, and manufacturers of and dealers in all machinery, apparatus, plant, materials, and things required for, or capable of being used in connection with the generation, distribution, supply, accumulation, or employment of electricity. The subscribers are:—W. J. Sutherland, Seaford, Sussex; J. Dunham-Massey, 55, Old Broad-street, E.C.; G. C. A. Kohler, 17, Fenchurch-street, E.C.; H. J. Alfred, 20, Moorgate street, E.C.; G. M. Gordon, 34, Colby-road, S.E.; W. Simpson, Wivenhoe, Wood Green, N.; L. L. Simpson, 26, Dover-street, W. Office: Broad Street House, Old Broad-street, E.C.

In connection with the above Company the following are the main facts of the agreement to be entered into:—Made between Patrick Kennedy, of 105, Johnson-street, Brooklyn, in the State of New York, U.S.A., and Charles J. Diss, of 334, Pearl-street, Brooklyn (called the "vendors"), of the one part, and the Company of the other part. The vendors are the owners of patents Nos. 16,934 and 16,938 of 1891, and No. 9,014 of 1892 (Provisional Specification), for "improvements in secondary or storage batteries, and the Company has been incorporated with a view to the acquisition and working of the said patents. It is therefore agreed that the vendors shall sell to the Company the said inventions and all patent rights granted or to be granted to the vendors for improvements in storage batteries, except in the United States of America. The consideration for the said sale to be £100,000, to be satisfied by the allotment to the vendors or their nominees of the whole of the present nominal capital of the Company. The vendors have agreed to pay all the preliminary expenses of the formation, registration and floating of the Company, down to and including the first allotment of shares, and have also agreed to pay to the Company the sum of £2,000 for use as working capital.

READING ELECTRIC LIGHT COMPANY (LIMITED).—The statutory return of this Company, made up to June 2nd, has been filed. Out of a nominal capital of £75,000, in £5 shares, 7 shares have been taken up, no calls made, and nothing paid. The original signatories are the only shareholders.

SIEMENS BROTHERS AND COMPANY (LIMITED).—The annual return of this Company, made up to July 1st, has been filed. The Company was registered on December 28, 1880, with a capital of £400,000 in £100 shares, to take over and carry on as from January 1, 1881, the business of telegraph engineers, electricians, and electrical contractors, carried on by Ernst W. Siemens, Charles W. Siemens, and Carl H. Siemens, under the style of "Siemens Brothers." By special resolution, passed January 8, 1883, and confirmed January 23th following, the capital was raised to £500,000 by the creation of 1,000 new shares of £100 each. At the time of making up all the shares had been taken up, £85 per share called, and all calls (£425,000) paid or considered as paid. No difference is made in the return between the amount paid and that considered as paid; but it appears by other documents that 3,993 shares were issued with £75 considered as paid on each share.

CITY NOTES, &c.

BABCOCK AND WILCOX (LIMITED).—The Directors recommend that the following dividends be paid for the half-year ended 30th June last:—At the rate of 6 per cent. per annum on the preference shares, and at the rate of 15 per cent. per annum on the ordinary shares.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended Aug. 28th were £895, as against £717 for the corresponding period of last year, being an increase of £88. The total receipts for half-year amount to £6,953, against £6,397 in the corresponding period of 1891, being an increase of £556.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Aug. 26, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,283.

CRICKET.—A match was started at Cadiz on the 20th ult. between the C. S. "Mirror" eleven and the eleven of the Eastern and Spanish National Telegraph Company, but was unfortunately brought to a close after the "Mirror" eleven had scored 60, owing to an accident to the awning injuring one of the players.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 747.—Vol. XXIX. FRIDAY, SEPTEMBER 9, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

In the publication of an article by Dr. J. Hopkinson and Mr. B. Hopkinson, which will be found in the present issue, we welcome a new worker in the field of experimental science. The present investigations of Dr. Hopkinson and his son, which were briefly alluded to at the British Association, set at rest what doubt remained as to the presence of magnetic viscosity or magnetic lag in iron, up to a frequency of 125 cycles per second. The conclusion which has been arrived at by these authors, that the hysteresis curve is the same for quick cycles as for slow ones is the more important, as it was arrived at by experiments with alternating currents, the shape of which departed widely from the simple sine curves so dear to many mathematical minds. Prof. Ryan made some of these sine functionists very uncomfortable, and now Dr. J. Hopkinson and Mr. B. Hopkinson display most erratic curves which suggest at first that some very queer dynamo was used. However, there is always Fourier's theorem to fall back upon.

But on closer examination of the conditions of the research we find that the figures accompanying the article do not at all indicate the character of the voltage curve of the dynamo used. The curves B only show the voltage impressed on the inductive resistance H, and must differ from the voltage curve of the dynamo in consequence of the voltage needed to force the current through the resistance R. This circumstance appears to us to explain the fact that the curves B in the various diagrams differ widely from one another. The accuracy of the results could, indeed, be tested by deducing the voltage curve of the dynamo from the curves A and B, and seeing whether it is the same for all the figures.

The practical investigation of hysteresis and of eddy currents has engaged the careful attention of Messrs. Evershed and Vignoles, and we hope very shortly to publish the continuation of their communication which appeared in these columns on October 15, 1891. These experimenters have held that no magnetic lag exists within the limit of ordinary frequencies. Their forthcoming article will treat, amongst other matters, of the creeping of the induction to a new value between two successive observations; and the difference between the observations of Dr. J. Hopkinson and Mr. B. Hopkinson by their two methods might be explained in this manner. The difference begins just after the iron has passed through its nearly unstable condition, and if left to itself a little, while the necessary manipulations of the instruments are made, the induction will rise slightly, and thus each step deviates from the true curve.

There are now several instruments by which dynamo makers may test the magnetic qualities of samples of iron, and one of the most simple of these, exhibited by Dr. H. E. I. G. Du Bois at the British Association at Edinburgh, was described in our columns a fortnight ago. An uncertainty may arise in the use of such an instrument as this, or the "permeameter" of Prof. S. P. Thompson, on account of imperfect contact with the end of the test piece. Dr. Du Bois provides an automatic magnetic plunger which will give a definite pressure on the end of the test piece, but careless surfacing or squaring of the end would render this useless. If the ends of the test pieces were shaped to a definite convex curve, or being fairly flat, were held between convex clamps, the contact would be practically the same each time, and allowance would be made as part of the air-gap of the instrument. But in testing iron wire and sheet, even convex or conical clamps could not be relied upon to make uniform contact unless the samples were carefully made up solid, and surfaced. The air-gap of the instrument, as shown at Edinburgh, would bear a little reduction, and it seems that a small gap, say of brass, might be introduced at each end of the test pieces, without shearing the axis of the diagram too far backwards. Careful surfacing of the ends would not then be necessary.

Prof. Ewing's magnetic curve-tracer had only assumed a practicable form shortly before the meeting of the British Association, and it was almost too early then to criticise it. The conditions which limit the speed of the instrument were not made quite clear. Prof. Ewing, in the discussion which followed his description of the instrument, repudiated any mechanical inertia, but did not claim a higher speed than 20 per second. It is clear that apart from the natural period of the strained wires, which may be very high, there must be some inertia in the mirror; he alluded, indeed, to "little ripples due to inertia of the working parts." It would seem that ripples such as those which are clearly visible in the lower part of the larger diagram, which were published on page 385 of our issue of August 12th, were due to the natural vibration of one of the wires, or to the mirror under the

Digitized by Google

strain of the springs, and which, at two cycles per second, appear to correspond to about 70 vibrations per second. If the spot of light described a circle, the motion of the mirror would be continuous and gyratory; it must, however, in practice offer some opposition to sudden reversal of motion, and we should like to know to what extent this interferes with the running of the instrument up to 100 per second. Something striking ought to happen when the period synchronizes with the period of these ripples; but it ought to run smooth at still higher speeds.

THE efficiency of the modern first-class dynamo is as near perfection as need be, and its durability is but little less perfect. It is said to be expensive, but the profits in mere dynamo building are probably as small, if not smaller, than in the construction of any other high-class machinery. The real way of putting the case is, that most dynamos give very little output for the money, and the higher the class of design and workmanship, the less is the output per £1 and per lb. MM. REIGNIER and PARROT have recently made a dynamo which is said to give 32,000 watts at 500 revolutions, with a weight of only 1,600. In our Paris Notes, dated March 11, 1890, we gave some particulars of a machine constructed by MM. REIGNIER and BARY, which gave 10,500 watts at 1,800 revolutions, with a weight of 580lb. The armature of this machine resembles that of FRITSCHE, of which so much was expected some three or four years ago. There may have been structural difficulties in the way of this form of armature which is remarkable for what the French call "*puissance specifique*," but we understand that some progress is being made with the principle of "wave-winding." A brief account of the new machine will be found in our Notes, and a translation of a communication by MM. REIGNIER and PARROT to the Académie des Sciences upon the subject will be found in another column.

THE prize of five thousand francs—about two hundred pounds—which was awarded by the municipality of Paris to Prof. ELIHU THOMSON in the contest for the best electric meter, has been devoted by him to "serve for the development of the theoretical knowledge of electricity" by the offer of a prize for the best essay on one of certain appointed subjects. These will be found among our Notes.

THE custom of offering prizes for essays or other scientific work is a peculiarly French idea, and one which cannot, on the whole, be said to have elicited anything of great value. The best work continues to be divided between the commercial man, who is always with us, and the amateur, about whom Prof. SCHUSTER has recently made some trenchant remarks. Looking back over the past ten years, we find that in 1882 the Boidin prize of a gold medal and 3,000fr., offered by the Académie des Sciences, for the best essay on the Origin of Atmospheric Electricity was not awarded, as no sufficiently good work was sent in. In the following year, and again in 1886, they proposed the curiously-worded subject of "Perfection in each Important Point of the Theory of the Application of Electricity to the Transmission of Work." But only one memoir was sent in, and without success. In 1884 the Société Nationale d'Encouragement pour l'Industrie Nationale offered a prize of the same value for an essay on the transmission of "natural forces," one of 1,000fr. for the indication of temperature at a distance, and 3,000fr. for "strong and simple apparatus capable of announcing safely, regularly, and automatically, the passage of a train at any distance." The KING OF THE BELGIANS made the handsome offer of a prize of £1,000 annually, and in alternate years for international competition. The subject in 1886 was "The Progress of Electricity Applied to Motive Power and Illumination: its Applications and Economical Advantages." In 1887 the Société d'Encouragement set the subject, "A small motor designed for a family workshop, to be worked separately, or to be connected with a central factory," and offered 2,000fr. as a prize, and repeated the subjects of transmission of power, train indicator, and thermometer indicator, with a prize of 3,000fr. each, and added another prize of the same value for the discovery of a "perfect process of transmitting to a distance motive power to agricultural machines." In 1888 the Belgian Society of Electricians offered 250fr. for the best essay on the elementary principles of electricity. We hope that the Elihu Thomson prize will do more than these.

THERE are a good many cases in practical work in which the principles of maxima and minima might be applied, if it were not that the mathematics are too difficult for ordinary use. By plotting a few simple cases a curve can generally be drawn which shows the general position of the maximum at a glance. A small departure from the maximum in some cases does not matter; as, for example, the best point of incandescence of a glow lamp, because the curve being tangent to the line of maximum economy, it does not rapidly approach or depart from it. Several curious problems of this sort arise in driving dynamos, especially on a small scale, where the conditions are not easily recognised and where, too often, the arrangements are guessed. Up to a certain point, for example, by increasing the size of the fly-wheel of a gas engine, or by decreasing the size of the pulley on the dynamo, the faster will the latter be driven; but after this point is passed the engine will be pulled up in a way which perplexes the uninitiated, and similar puzzles arise in connection with the strength of the fields of shunt-wound dynamos.

IN some cases the conditions for exceeding the maximum so rarely arise that serious waste may ensue from neglect of the possibility of a decrease. It is so obvious that two lamps on a given circuit connected to a supply at 100 volts give twice the light of one, and that three will give three times the light, that it might be thought that if the lamps be indefinitely increased the total light will increase also. The usual limit would be the heating of the conductor. But on a large scale the fall of volts will become serious long before any serious heating arises. Such a case exists in a large building in London. The terminals of the supply company provide about 105 volts at no load; but owing partly to the resistance of long mains within the building, and partly to that of the meters and the feeder in the street, the volts at the lamps fall to 100 when about 220 amperes are passing,

Digitized by Google

and matters get worse with heavier loads, until at 500 amperes or so the lamps get only 94 volts. The sheer waste of 5,500 watts, or about three shillings an hour, is bad enough; but this is a trifle when it is remembered that 100-volt lamps run at 94 volts give only 0·62, or $\frac{5}{8}$ of their proper light. At about this point, adding more lamps does *not* give any more light, and 150 lamps of 16 candle-power might be turned off without affecting the total amount of light, but saving the cost of current which at this rate comes to the equivalent of nearly one shilling per unit. Until recently, gas engines have been used to assist in parallel, and the volts were easily kept up to 100. In order to "economize," under a new management these have been stopped, and great complaints are made of a huge "leakage" somewhere.

The calculations on electric stoves and electric smelting which we reproduce from the *Engineering and Mining Journal* in another column are suggestive rather than convincing, and may form the basis of further enquiry rather than guides for practical work. It is arguing in a circle to show that to heat by electricity generated by a steam engine would take more than twenty times as much coal as to heat by the direct combustion of the coal, for it is perfectly well known that a steam engine only yields about one-fourteenth of the energy of the the coal, and further losses must occur in transformation from mechanical into electrical energy. The performance of the electric stoves is worth recording, but the calorimeter method of estimating it—we cannot say measuring it—is open to several objections. It is in the production of high temperatures not easily attained by other means, and more especially in the concentration of the heat by generation at the very place where it is required, that electric heating promises to be most valuable.

Moscow Electrical Exhibition.—The Electrical Exhibition at Moscow was opened on the 27th ult.

Wurtemberg.—The central station at Wangen, equipped by the Maschinenfabrik Oerlikon is to be opened on November 15th.

Post Office Telephone Instructions.—An erratum occurs in the last paragraph but one of these instructions, and was reproduced in our last issue. For resistance of primary 5ω, read 0·5ω.

Valparaiso.—The local gas company has decided to build an electric central station in the best part of the town, and has entrusted the work to Messrs. Siemens and Halske, of Berlin.

Personal.—Mr. Reginald John Jones, M.I.E.E., A.M.I.C.E., desires us to state that he has renounced the surname of Jones, and will in future assume and use the surname of Wallis-Jones.

The Telephone and Local Authorities.—The St. George's-in-the-East Board of Guardians have asked the Local Government Board to place the whole of the casual wards of London in telephonic communication.

Fatal Accident at Cologne-on-Rhine.—A workman was recently killed at the Municipal Central Station at Cologne-on-Rhine. The whole of the floor of the regulating room has been carefully insulated, and the deceased man was wearing rubber gloves at the time of the accident, so that, as he was alone, it seems difficult to determine how it was that it occurred.

Technical Classes.—Information about the courses of instruction in mechanical and electrical engineering at the Royal College of Science, Dublin; the University of Glasgow, Durham College of Science, University College of North Wales, the Municipal Technical School, Manchester; and the People's Palace Technical School, will be found in the advertisement columns of the present issue.

Coast Communication in the Isle of Man.—A line of telegraph has recently been completed between Ramsey and the Admiralty signal station at Port Cranstal, six miles north of Ramsey. A wire has also been set up from Peel to the Admiralty station on Peel Hill. A survey has been made for a telephone line to the Admiralty station on the south of the island, and when this is finished the whole of the coastguard stations on the island will be in telephonic communication with the postal telegraph system.

Hastings.—The Hastings Town Council decided on Friday last to light the whole of the Esplanade from the Fish Market to the end of West Marina, a distance of three miles, with electric light arc lamps 80 yards apart. At present the front is illuminated jointly by electricity and the "Whitehall" gas lamp.—The local Electric Light Company undertake to provide, for three years, 52 arc lamps, 80 yards apart, at £25 per lamp per annum. The total cost will be £1,300, and it is estimated that the new system will effect a saving of £68 a year on the present charges.

The Marseilles-Oran Submarine Cable.—On the 14th of last month the steamer "François-Arago" (late "Westmeath") left Calais, having on board the Marseilles-Oran cable. This is the first time a French ship has been entrusted with a cable made by a French firm under French supervision. This cable has been made to the order of La Société des Téléphones. The conducting wires were made at Bezons, and the external casing at the Calais works, which are situated close to the Carnot basin, so that the cables can be passed directly from the tanks on board ship. These works, which employ 300 hands, have already turned out over 3,000 miles of cable.

High-Speed Electrical Transit.—Every now and then a new scheme is brought out, says *Industries*, for running trains at a speed of 100 miles an hour or more by electrical means. An express locomotive develops, say, 1,000 H.P. at 60 miles an hour, yet the rapid-transit enthusiast proposes to work with about a quarter of this power, and to obtain nearly twice the speed. The proposal generally consists in a scheme for using very light rolling stock and very efficient motors. It would be well for those who are working at such schemes to obtain trustworthy information as to the air resistance of an ordinary train, and to find from that what power would be necessary to drive one at 100 miles an hour through still air, or against a head wind.

Exports of Telegraphic Apparatus.—The Board of Trade returns for last month are not so disappointing as those of July, either as regards the falling off in the total exports, or the decrease under the head of metals and articles manufactured therefrom. The figures relating to the exports of telegraphic wire and apparatus connected therewith still, however, compare very unfavourably with previous returns. The aggregate exports for the past eight months of this year are valued at fully £500,000 less than in the corresponding period of 1891. The following is a statement of the exports, in comparison with the corresponding figures for 1891 and 1890:—

	1890.		1891.		1892.
January to June.....	£721,712	.....	£984,530	.....	£675,835
„ „ July.....	56,575	.....	150,754	.....	25,906
„ „ August...	55,601	.....	112,690	.....	29,755
Eight months	£833,888	.....	£1,247,974	.....	£731,496

A Unique Water-Power Installation.—A unique water-power installation, so far as head is concerned, has recently been carried out by the Pelton Water-wheel Company in one of the Comstock mines at Virginia City, Nevada. The wheel is 36in. diameter, and is made of a solid steel disc, with the buckets riveted on to the periphery. It is running under a vertical head of 2,100ft., equal to 911lb. pressure; 460ft. of this head is obtained from a pipe line, and the remaining 1,640ft. from the shaft, down which the pipe line is run to the Sutro tunnel level, where the power station is located, and through which the water discharges after passing over the

Digitized by Google

wheel. The wheel runs at 1,150 revolutions, with a peripheral speed of 10,804ft. per minute, or about 120 miles per hour. A nozzle tip, ½in. diameter, gives under above conditions 100 H.P.

The Influence of the Electric Light on Paper.—In a communication "On the influence of Incandescent Electric Light on Paper made from Wood-cellulose, and its Deterioration through Exposure," Mr. J. Wiesner states that he finds that after exposure of 552 hours to a light of 144 c.p. no yellowing takes place, whilst with gas light after 240 hours of 50 c.p. a slight degradation of tone is noticeable. It is to be observed that the action of light may proceed for some time without producing any visible effect; but on treating such paper with potash solution of such a strength as only to give a faint yellow colour with unexposed material, a brownish stain is developed. Incidentally he mentions that whilst direct sunlight after a few hours causes a change in paper made from wood pulp, bright diffused daylight can only effect a similar change after several days.

The Printing Telegraph in a Steel Mill.—The Illinois Steel Company, of Chicago, has introduced a printing telegraph system in its mills, by means of which the men at the reheating pits can inform those at the finishing end of the mill as to the heat numbers of the ingot, the ingot numbers, and the number of rails to each ingot, so that the proper number may invariably be stamped upon each rail that leaves the mill. In addition to these numbers the "pit" and "hole" designations are also despatched by the same means. It is stated that the mechanism works in a very satisfactory manner. The transmitter is in charge of one of the men at the reheating pit, and the receiving instrument is in charge of a boy, who reports on a blackboard for the use of the stamper the different numbers and letters as they are printed on the tape by the receiving instrument. The distance between the two is about 350ft.

Aluminium.—The variety of new uses which, under the influence of the glut in the aluminium market, caused by the advent of the electric process, has been found for aluminium is very astonishing. We are now told that it has been found that powdered aluminium can be burnt to as good effect as magnesium for lecture-room purposes, while it is considerably cheaper. On the other hand, this aluminium light is not so actinic as magnesium light. The powdered aluminium cannot be satisfactorily burnt in an ordinary spirit lamp; but the best result is obtained by using such a lamp fitted for receiving in the middle of its flame a supply of oxygen, and into which the powdered metal is simultaneously projected by means of a compressible india-rubber ball. The best light was secured by burning in this way a mixture of 100 parts of finely-powdered aluminium, 25 parts of lycopodium, and 5 parts of ammonium nitrate. It has been erroneously stated that this mixture leaves no smoke.

Electric Lighting for Lightships.—The U. S. Government lightship, No. 51, allotted to Cornfield Point, is a new departure in several respects, being provided, amongst other things, with steam-propelling machinery, and a complete electric lighting plant, which is situated in the after part of the main deck house. The plant consists of two horizontal high-speed engines, developing 8 H.P. with 70lb. of steam, from which power is transmitted by two Evans friction cones to two compound-wound Thomson-Houston dynamos, supplying electricity to 8 100-c.p. and 20 16-c.p. lamps, the former lighting the two signal lanterns situated on the masts, 49ft. above the deck, and the latter distributed about the vessel. Either of the dynamos is capable of lighting the whole vessel. The signal flashes are regulated by an automatic make-and-break apparatus in the engine room, and can be adjusted to give any desired combination of signals. The double system of wiring is employed throughout.

Lighting of the House of Commons.—During the present recess it is intended to make a considerable further extension of the system of electric lighting at the House of Commons. Under Mr. Plunket's *régime* most of the rooms on the basement and on the ground floor of the building, the various smoking and dining rooms, the library and tea room, the Ministers' private apartments, &c., have been furnished with incandescent lamps in substitution for gas, and upstairs the new illuminant has been introduced into the reporters' gallery and also into two or three of the committee rooms. The committee corridors are, however, still lighted by gas, and in the bulk of the committee rooms the only resource on dull and foggy days is the old-fashioned colza dirty and smelly lamp. It is not proposed to make any alteration in the lighting of the House itself, for the elaborate arrangement of gas lights above the roof took many years to bring to perfection, and is connected with the ventilation.

The Regnier and Parrot Dynamo.—According to a Paper by Mr. James Chappuis, published in *Le Génie Civil*, Messrs. Regnier and Parrot have made a machine weighing only 1,600lb. which gives 32,000 watts at 500 revolutions. This dynamo has a field with four pairs of magnets arranged so that the two opposite poles are north and south as in an alternating current machine. The armature is the same as that of Fritsche or Deroziers in principle, but is not made up entirely of copper or of iron, but of a combination of both. Each armature strip is made up of a strip of soft iron with copper on each side of it. The connections are made by means of copper pieces resembling commutator sections. The armature is, of course, very thick, as the iron carries the induction easily. The details of this machine are as follow:—The armature has 264 turns, and each conductor carries 200 amperes; the output is thus 800 amperes and 40 volts at 500 revolutions. The armature conductors are half copper and half iron, and one turn has an area of field of 47 square inches. The insulation is 0·055in. between the conductors, but the makers expect to reduce it to 0·016in. Each electromagnet has an area of 29 square inches, but the armature iron in use under each magnet pole is only 9·6 square inches. The armature is 27in. diameter outside. Commenting upon this machine, *Industries* observes that from this it will be seen that the extraordinary result is obtained by having an enormous number of ampere turns on the armature, namely, 13,200. As the armature is well ventilated there can be little heating, but further information should be forthcoming as to the sparking. There must also be some waste of power in the armature due to its lamination not being in the right direction.

Electrical Nomenclature.—The comments on electrical subjects which appear in the *Journal of Gas Lighting* are generally none the worse for coming, as a rule, about a fortnight or three weeks after the events to which they refer. From this week's issue we extract some observations which we recommend to the attention of some of our readers:—There was a somewhat interesting, although apparently fruitless discussion, at the recent British Association meeting upon the nomenclature of certain electrical units. The various applications of electricity to which the world is now being treated are attended by the appearance of many phenomena, attesting the operation of the unknown form of energy, which, for the want of a better word, we may term "symptoms." A closed wire circuit, and the dynamo which keeps up the supply of electricity in the circuit, and many things lying within or near the circuit, manifest a multiplicity of symptoms indicative of the activity or whatever it is that is going on within and about them. It is the function of our professors of physics to bring these symptoms to book as fast as they are distinguished; and in order to do this, it is necessary to name them. Unhappily, the language of men does not contain any undistributed reserve of words which can be drawn upon for the nomenclature of newly-discovered things, whether the things happen to be mountains in Africa, strange worms in mud, or manifestations of what is called electricity. Consequently, terms have to be created to fit the new things; and when the nature of these is not fully understood, the most expressive word that can be applied to them remains, as Matthew Arnold would have said, language "thrown out" towards the Unknown. If the word happens to stick to the thing, people grow in time to talk about it as though it were the thing itself, which is the way to confusion. The electricians have great difficulty in regard to their nomenclature. This is hardly to be wondered at, since, to the initial difficulty of the unknowableness of the things sought to be named, they have added the further obstacle of conspicuous want of tact in their suggestions of words for them.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 485.*)

17. Paying out (*continued*).—In some of the earliest cable-laying expeditions accidents due to insufficient brake power, or insufficient number of turns of cable round drum have occurred. If the grip of the cable on the drum is not sufficient, it will continue to pay out, even though the drum is pulled up dead by the brake. Mr. J. W. Brett relates an accident of this kind while laying the 1855 and 1856 Mediterranean cables between Spezzia, Corsica, Sardinia, and Bona, when two miles of cable ran out of the ship in five minutes, flying round even when the drum was brought up dead. He attributed it to the fact that the cable was only taken three times round the drum, and that being of so large a type, there should, at least, have been five turns to afford sufficient gripping surface on the drum. With improved methods and machinery accidents of a like nature are happily of very rare occurrence, and the writer only recollects one case within several years, this being the fracture of a brake band. On this occasion the engineer in charge of the gear managed to throw in the clutch of the train of gear in time to avert a seriously rapid uncoiling of cable from tank. Life lines are hung from eye-bolts, fixed in the angle iron round top of tank at short distances, by means of which the men at work inside can make good their escape in case of the cable taking charge. Should a loop or twist occur, which might form into a kink if not straightened in time, the ship is stopped immediately. On cable ships special smartness is necessary in handling the ship. On some ships, as, for instance, on the "Electra" (Eastern Telegraph Company), in addition to the ordinary hand-wheel for moving the links over for reversing

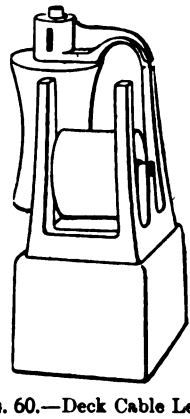

Fig. 60.—Deck Cable Lead.

main engines, which takes an appreciable time, there is another lever which, when operated, admits steam to a small vertical cylinder, the piston of which acts on a water ram, and moves over the links rapidly. In fact, with this system, known as Brown's reversing engine, the links on both high and low pressure eccentric rods are shifted over in little more than the time it takes to pull over a lever. An electrical circuit to a bell on the bridge is also arranged to be closed automatically whenever the links are over to "astern" when the orders on the telegraph are "ahead," and *vice versâ*. This arrangement is not altogether satisfactory to the engineer, as, however smartly he may follow his orders, he is frequently obliged by the position of his cranks to reverse for a moment in order to carry out the order.

On its way from the tank to the drum and paying out sheave the cable passes over guide pulleys or leads placed at suitable distances on deck. One of these is illustrated in Fig. 60, in which there are a pair of rollers on axes at right angles. The affair is placed with the vertical pulley on the side towards which the cable bears; the course of the cable over deck not being straight along the whole distance. Guides are provided on either side of the rollers to keep the cable from shifting.

* All rights reserved.

Surface currents and tides have a marked effect on rate of paying out. The rotometer may register as much as eight knots of cable going out per hour, if the set of the current is with the ship. This is, of course, not too great a speed if the current is carrying the ship along three knots over the ground, independently of her own speed of five knots, through the water; but the effect must not be mistaken for paying out too much slack and strain thrown on the cable by setting up the brake. Under ordinary conditions, when the tide or current is not flowing in the ship's course, the fact of eight knots leaving the ship when she is only moving five, would, of course, mean 50 per cent. more slack than necessary, and great waste of cable. The cost of cable when new being over £200 per mile, it is an important matter to pay out only just what slack is necessary for laying without strain, and for repairs. The strain or tension on cable indicated by the dynamometer as ship pays out should represent little more than the weight of the length of cable in water suspended from ship, which varies according to depth and type of cable. With light cables in 1,000 fathoms the strain allowed is about 12cwt. to 15cwt. The brakesman watches the movements of the dynamometer pointer on the scale, and if any sudden strain appears, such as on entering deeper water,

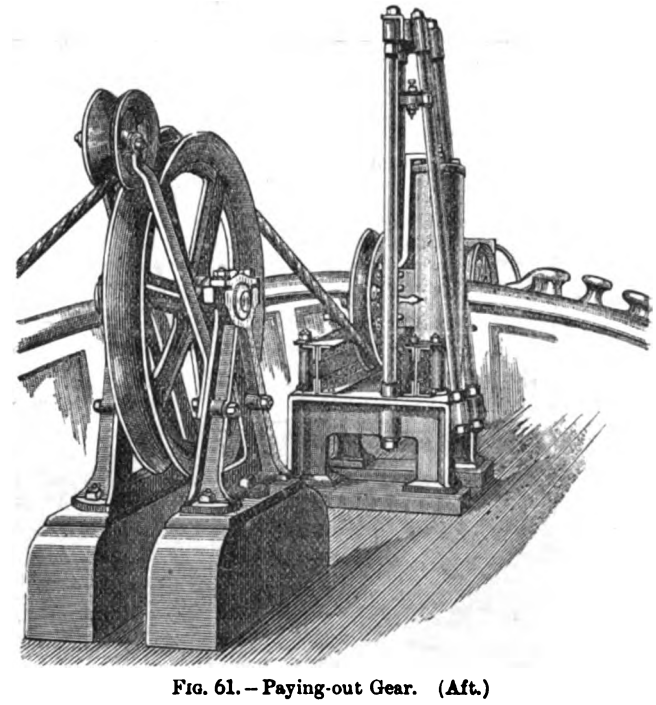

Fig. 61.—Paying-out Gear. (Aft.)

he slacks his brake a little to take off the extra strain. If, on the other hand, he finds the strain reduced, such as would happen in a belt of shallower water, he checks the cable to prevent too much slack going out. The speed of ship through the water is ascertained by the log, but this gives no idea of her speed over the ground as affected by tide or leeway; and while the direction and force of the tides are generally known, and the ship's course can consequently be kept straight over ground by making due allowance, it is a more difficult matter to make any correct observation of the surface currents, unless any land is in view to go by.

The dynamometer, leading pulley, and stern sheave, over which the cable finally rides into the sea, are illustrated in Figs. 61 and 62. It is usual to fix these on the port or starboard quarter, to give the cable as straight a course as possible from the forward drum. In large cable-laying steamers, which pay out over stern, the drum and brake are fixed aft, and a steam engine coupled to them. With the steam gear a cable can be picked up again, on the same drum, if a fault has been payed overboard, without the necessity of bringing cable end round outside ship over bow sheave to picking up drum. In repairing steamers the quarter deck is of the general appearance shown in Fig. 61, the view there given representing that on the cable ship "John Pender" (Eastern Telegraph Company).

Digitized by Google

The modern type of cable ship is well represented by the "Electra," belonging to the Eastern Telegraph Company.

Built of steel in 1884 by Messrs. Robert Napier and Sons, of Glasgow, she measures 230ft. in length, 32ft. beam, by

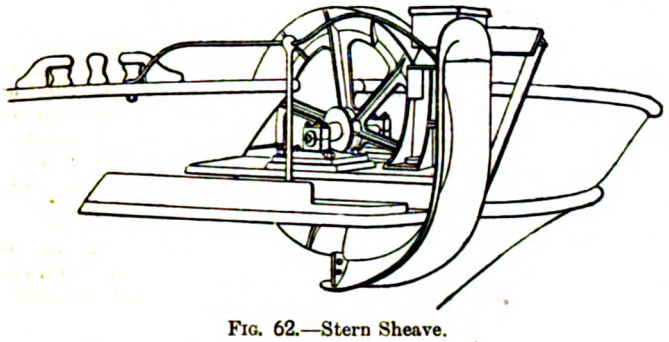

FIG. 62.—Stern Sheave.

24ft. depth from awning deck, and can steam 11 knots. In regard to the cable gear, which was made and fitted throughout by Messrs. Johnson and Phillips, it is noticeable that the picking up machinery forward is, together with the double-cylinder steam engine driving it, fixed on the main deck, while the starting and reversing levers and brake wheel are taken through on to the awning deck. This is a most convenient arrangement, and better than having all the weight on the upper deck.

The upper part of the cable drums and brake wheel appear through openings in the awning deck, so that the course of the cable as it passes the gear can be fully observed while there is perfect control of the gear on this deck in full sight of the bow sheaves and dynamometer. Two dynamometers are fitted forward, one for each drum, for picking-up and paying-out over bows, and triple bow sheaves are fitted. Steam is taken to the gear from the main and donkey boilers so that the gear can be worked in port if cable required to be turned over. A special advantage to a cable ship is the addition of a separate circulating pump for keeping main condensers cool during stoppages or slow-speed runs; and on board this steamer one of J. and H. Gwynne's centrifugal pumps, coupled direct to small vertical engine, has been fitted for this purpose. The dimensions of this vessel's tanks have previously been given in para. 10 on capacity of tanks. The smallest tank (No. 1 forward) is generally used for coiling grapnel rope, while No. 2, the largest, and No. 3 are the two most generally in use, and will carry 150 miles of mixed cable when required. The two dynamos and the direct-coupled engines for supplying electric light on board, are by Messrs. Clarke, Chapman and Co., of Gateshead, and have been conveniently fixed on main engine-room floor, with switchboard on wall adjoining. Nightwork on deck is carried on by the aid of incandescent lamps arranged in groups of six and fitted under yard arm reflectors, one such group throwing light immediately under the bows. When making for the buoy by night, also, the search light on the bridge is found of great use. The illustration herewith produced (Fig. 63) of this fine vessel of 1,096 tons, whose work is chiefly in the Mediterranean waters, gives a fair idea of her proportions and build, characteristic also of the cable ships "Amber" and "Mirror" of the same Company, and the "Recorder" of the Eastern Extension Telegraph Company.

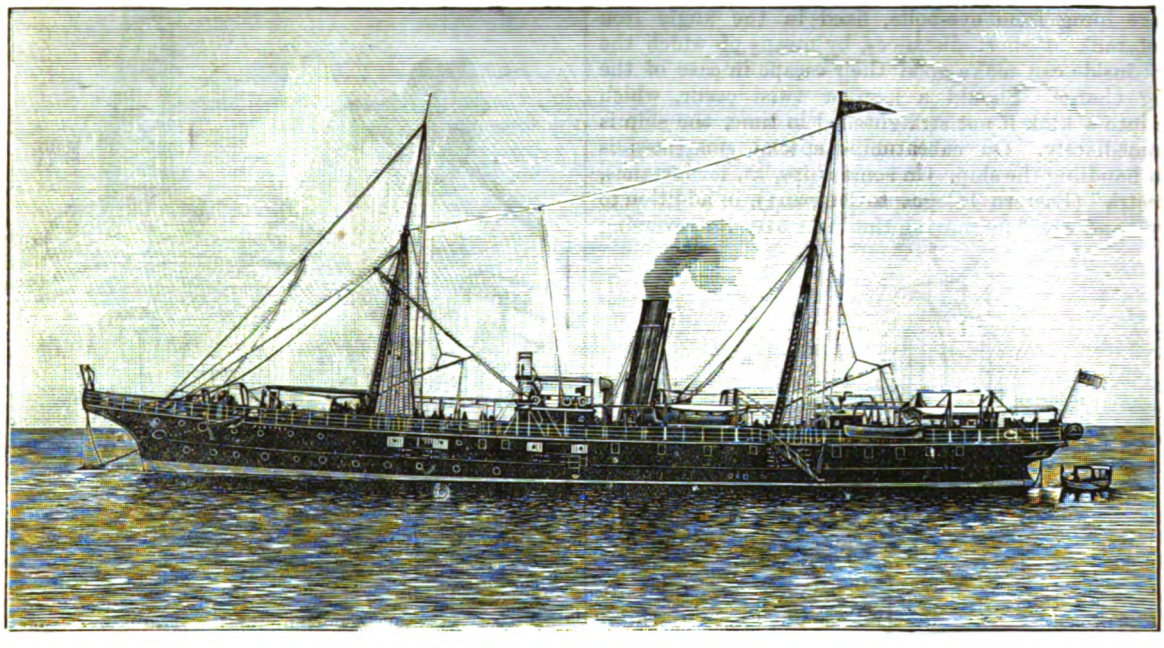

FIG. 63.—Cable Ship "Electra" (1,096 tons).

(To be continued.)

THERMAL CONTROL FOR ARC LAMPS.

Several attempts have been made to dispense with electro magnets in arc lamps with the view of simplifying the mechanism and giving a more definite and regular feed. Mr. S. E. Nutting has constructed a lamp in which a drum is geared to the rack of a carbon rod. This drum acts as a brake-wheel, allowing the carbon to descend slowly, but instead of applying the brake by means of an electro magnet, he employs a very strange device. A deep groove in the circumference of the drum is filled with stearine wax, and the end of a copper pin wound with fine wire is imbedded in the wax. The pin is fixed radially, two-thirds of its length is wound with wire, and the greater part of the bare end projects into the wax. The resistance of this winding is about 150 ohms, and a resistance of 500 ohms is placed in series with it, and the whole arranged as a shunt across the terminals of the lamp. It is found that the copper pin heats up under the current, and melts its way regularly through the wax, which closes up again behind. The depth to which the pin entered mattered little, whether much or little wax was melted the arc remained the same. The arrangement was said to work very well, and the lamp could be struck or rattled about without disturbing the feed in any way. The sensitiveness of the feed is due to some extent to the fact that the heating is as the square of the current. Such lamps have worked continuously for months.

Digitized by Google

Mr. W. E. Irish, of Cleveland, Ohio, has attacked the problem of controlling the feed of an arc lamp by heat in a different way. He calls his invention a thermo-electric arc lamp, but there is no thermo-electric effect properly so called. The upper carbon descends by gravity through a differential clutch, and the lower one is forced upwards by mercury. A lever pivoted to one of the side rods controls the clutch, and this lever is moved by a "thermal strip." It is not clear from the description on the photographs which we have received whether this is a compound or bi-metallic strip; but as it is coiled in a long spiral, we presume that this is the case. When the current enters the lamp it passes through this strip, causing it to expand. This raises the upper carbon by means of the clutches, but as the arc lengthens the current falls off, the strip contracts, and the clutches allow the carbon to feed. Mr. Irish provides a magazine of carbons, and claims that these can be fed in both from above and below without any intermission, leaving no ends or stumps.

The drawback to most of these admirably simple arc lamp mechanisms is that they will not automatically compensate for any irregularities in the quality of the carbons. When a soft spot gives rise to a "blower," the arc ought to be lengthened, and there should be some means of doing this in case of an accidental over-feed.

AN IMPROVED BATTERY ZINC.

Under the name of the D'Infreville Wasteless Gravity Zinc a very ingenious dodge for preventing the waste in stumps of zinc battery rods has been introduced in New York. The invention consists in shaping the zinc so that a number of pieces

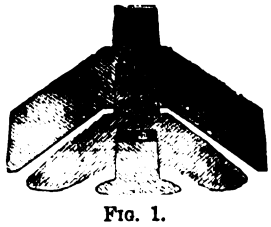

Fig. 1.

can be connected together by conical plugs and holes, and thus, a partially consumed piece may be connected to the bottom of a new casting. Every piece of zinc thus introduced into the battery may, therefore, be entirely consumed. In Fig. 1 a new zinc and two old ones in successive stages of consumption are shown in section, and Fig. 2 shows the arrangement of the battery. The zincs are firmly united by a few taps with a hammer.

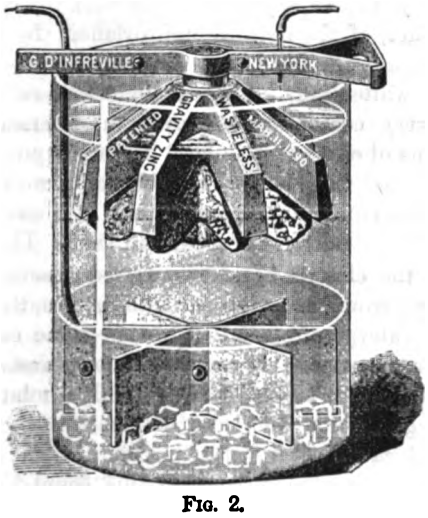

Fig. 2.

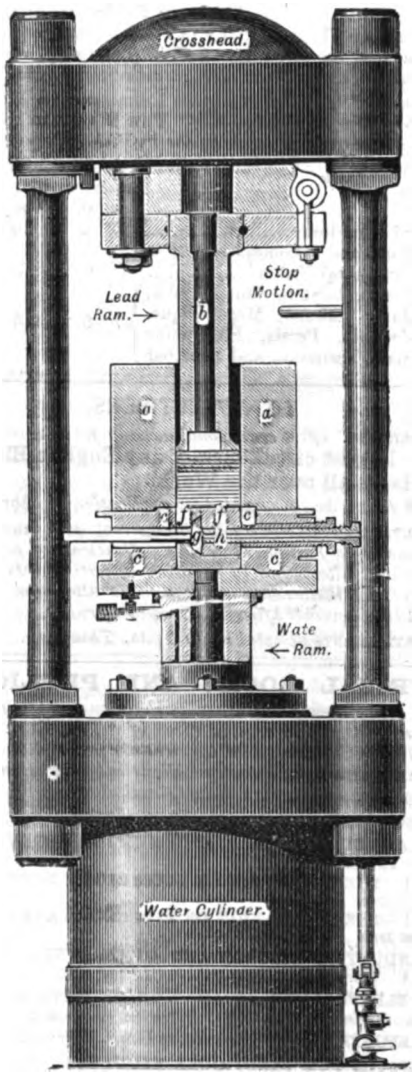
If it is found to be worth while to joint waste ends of arc carbons together by a patented process as is done at Concord, this system of "wasteless" zincs should prove to be relatively more economical.

PATENT MACHINERY FOR LEAD AND CABLE TRADES.

We illustrate herewith special machinery designed for the covering of electric cables with lead or other metallic substance, and for the manufacture of lead pipes, which is manufactured under patents owned by Mr. Alexander Wylie, of Messrs. J. and W. Weems, Perseverance Ironworks, Johnstone, Glasgow.

The illustration shows the general arrangement of the hydraulic lead press. The lead container is filled with lead or other metals, to be operated upon by either a hollow plunger for ordinary lead pipes or by a solid plunger for electric wires and cables, and in order to prevent the cable from being injured by heat specially-designed water chambers are provided allowing of a continuous circulation of cold water round the hollow block through which the cable runs. The rings or dies requisite for regulating the thickness of covering are placed in the hollow block, and the guiding cores are secured by regulating screws to the container. These guiding cores are either hollow or double cased to allow of



the flow of cool water previously referred to. To prevent the metal passing through the side of the hollow block the core is screwed up against the regulating ring or die, the cable is passed through the core, and when the metal is solidified in the first charge the core is unscrewed back as desired to allow the metal to pass round and cover the cable. By this means the cable is only exposed at the point of contact, a feature the importance of which cannot be over-estimated. The improvements claimed by Mr. Wylie are (1) the container (*a*); (2) the plunger (*b*); (3) the cellular base (*c*) with the water chambers; (4) the two-part core and die seat (*f*), and the conical guide (*h*). By means of the latter the regulating die (*g*) is secured in position, the core seat supporting the guide and completing the whole. By this machine lead-covered cables in continuous lengths are manufactured, with any required thickness of covering, and of any diameter between ⅛in. and 3in.

A number of these machines are in use by the leading makers of lead-covered cables in this country and abroad. The lead presses for making lead pipes, lead-encased tin pipe, and for solid block tin pipe are at work in all the principal lead works at home and abroad.

FIRE RISKS AND RULES IN AMERICA.

The subject of fire risks, insurances, and rules and regulations for wiring, turns up from time to time, and it is safe to say that on every occasion the result is a strengthening of confidence in electrical work. The insurance companies are beginning to bestir themselves in the United States, and a meeting of "electrical insurance experts" has been held for the purpose of discussing a uniform set of rules for electrical work. The subject of fire risks in electric lighting has been brought before the American offices on several occasions by other associations, but no spontaneous meeting of any importance appears to have been held by them. We understand that during 1889 there were 119 fires due to electrical causes in the whole of the United States, and that in the following year there were only 73. This decrease may be traced to two tendencies: one, of bad insulation to break down and thus by degrees wiping out bad work by conflagrations, and the other, of the natural improvement in the quality of materials and workmanship. The insulation consisting of cotton and white lead, known as underwriters' wire, was at one time very commonly employed in America, and owing to conditions of climate it sufficed for many purposes, and is, we believe, even now used with safety for some interior work, although it was unanimously condemned at a meeting of representatives of the Edison Companies in 1887. This trust in the dryness of the climate has, however, led to serious accidents, and, jumping from the frying-pan into the fire, the non-inflammable non-waterproof insulation has, in some cases, been exchanged for a covering which will, indeed, resist damp, but, consisting chiefly of tar and wax, is highly combustible. There has been a great improvement of late both in the manufacture of insulated cables and wires in the United States, since several varieties are imported into this country, and some of them are found to satisfy the most stringent requirements.

We find the American journals teem with descriptions of improved contacts, switches, and other safety devices. Glancing through the last number of the *Electrical World* of New York we find a sufficient number of examples to show which way

Digitized by Google

the wind is blowing. It is true that a wire covered with woven canvas is illustrated among the advertisements on the first page, but it is in company with four other advertisements, three of which claim high insulating qualities. The next two pages contain seven claims for mica, together with a china cut-out; further on is a patent insulating material, then hard rubber, slate for switchboards, then a relapse into wood rosettes and cleats; but soon after come porcelain insulators, porcelain base switch, weatherproof wire—whatever that may be—and porcelain lamp sockets. At the end of the paper we find more porcelain, kerite, mica, okonite, another porcelain cut-out, general porcelain fittings, special cut-out for motors, &c. So much for the advertisements which may be taken as a fair guide of what is going on. In the body of the paper we find an article on tests of fireproof wire, a ceiling cut-out—apparently porcelain, a "bug" cut-out, improved insulator pin, a notice of an Insulator Company, and a protest of the New York Board of Fire Underwriters against the trolley system. Among the patents are two safety switches, armature insulation, safety fuse, and a new insulator. This is a pretty good list for a single number taken at random, but to it we must add the announcement of the meeting of insurance experts to which we have already alluded, an article by Mr. G. Binswanger, on "How Fire Losses are Prevented in England," and two editorial notes on the subject.

Mr. Binswanger begins by expressing surprise that the insurance companies in America charge a special premium for buildings in which electricity is used; but at the conclusion of a long letter devoted almost entirely to the praises of the Phœnix Office and its electrical inspector, he admits that the "fittings, such as switches, cut-outs, &c.," which he has received from America, "are so poor from an electrical point of view, according to our notion, that no inspector of central stations or fire officer would allow them to be used in England." The insurance offices in the two countries have taken very different courses of action with regard to electric lighting. Here regulations were imposed which were highly unpopular, not so much on account of stringency, but by reason of their vagueness and need for separate interpretation for each job, the interpretation often coming only after the work had been done. In America, on the other hand, the companies did nothing, but merely raised the premiums. One result was the establishment in May, 1890, of the Electrical Mutual Insurance Company, which provided for intelligent inspection. It took risks amounting to $2,897,587 last year, and did not incur the loss of a single dollar. When brought into competition with this Company other offices reduced their premiums to one-half. The Fire Underwriters' Association of Philadelphia insures more than 5,000 buildings supplied with electric light and power, and during last year there was not a single fire which could be attributed to electric wires. Under these circumstances, we can hardly agree with Mr. Binswanger in his general advice to the American nation. "In my opinion," he writes, "the best way to remove the difficulties of which you speak is to get an authority in America like Mr. Musgrave Heaphy."

Rules for insulation and proper erection of electric work have been considered by the National Electric Light Association, a body which appears to successfully combine the most useful features of our London Chamber of Commerce, British Association, and Institution of Electrical Engineers, but their attention has been directed chiefly to the protection of high-pressure, arc-light circuits. If the fire offices of the United States can agree upon a single set of rules, self-explanatory, and with intelligent specification of work and material, they will have done more than ours can accomplish.

The introduction of well-designed fittings is evidently making rapid progress in America without the assistance or compulsion of insurance offices, and they have makes of insulated wire which, if not up to the best qualities of our vulcanised rubber, are amply sufficient for all ordinary requirements, especially in a dry climate. From the editorial note in our contemporary, we understand that the nonconformity of the rules, rather than their severity, is the present trouble. This is a smaller evil than the nonconformity in the interpetation of one important set of rules, which has caused so much annoyance with us. It seems under these circumstances that there is not much to complain of. Americans led the way in electric lighting at a pace which we did not care to follow, and now they are finding disadvantages of cheap and nasty work, and have already adopted many of the precautions which have been initiated on this side of the Atlantic for low-pressure work, and are at the same time improving the high-pressure arc circuits which have given rise to most of the accidents. By thus allowing matters to right themselves they seem to be taking the best possible course.

REVIEWS.

Formulaire de l'Electricien. By E. Hospitalier. Dixième Année. 1892. (Paris: G. Masson.)

With engineering pocket-books compactness bears the same relation to all other considerations that charity does to all the other virtues. The ideal pocket-book should contain nothing but clearly arranged well-digested tables, formulæ, and tests likely to prove of use to the engineer; illustrations, other than curves and diagrams, should be tabooed, and the limited dimensions of the average pocket should not be lost sight of. The "Formulaire" for 1892, with its 400 odd crown octavo pages of closely printed matter and its goodly muster of formulæ, many of which perhaps ought to be, but certainly never are, used by the engineer in the flesh, scarcely comes up to standard requirements. However, the author in this respect errs in excellent company. Slightly expanded and printed in larger type, the "Formulaire" would be an addition to our list of practical text-books; considerably compressed it would take a high rank among the numerous electrical pocket-books which have issued from the Press.

To descend from generals to particulars, we may instance the sub-section dealing with "mechanical generators of electrical energy," which takes up 20 pages, and is practically nothing more than a collection of catalogue extracts. Had a dozen leading makes been selected, and had the principal data connected with them been reduced to a common denominator and arranged in a manner admitting of rapid rough comparison, a potential purchaser, in a quandary as to the particular pattern best suited to his purpose, would have been given something to the point.

Electricity. By J. T. Sprague. Third Edition. 1892. (London: E. and F. N. Spon.)

In his preface to the third edition of this well-known work we learn that "one-third of the book is re-written; nothing of consequence has been omitted, but to make room for the new matter some of the less important illustrations have been set aside, and all unnecessary words cut down; but the work as a whole remains what it was, the expression of original thought and work, not a mere orthodox text-book."

These last few words express most clearly and comprehensively the position which this book ought to take. It cannot be recommended to beginners, but no student who has been well grounded in electrical science should omit to consult it, if only to obtain an excellent account of the history of the theories and applications of electricity. Among the useful practical features of Mr. Sprague's work the tables are perhaps the most important. He was the first to draw up a good table of the resistance and weight, &c., of copper wire, and though many

Digitized by Google

others have since been calculated the smaller tables of conversions of constants are nowhere given in a more useful form.

While Mr. Sprague was the first to graduate a galvanometer to read the current directly, using, for want of a better, a unit of his own—the chemic—the pages devoted to galvanometers are perhaps the least satisfactory. The chemic and the equivolt still linger in the text and in the glossary.

The chapters on electro-metallurgy are among the most valuable. In the preceding chapter on electrolysis we find that Mr. Robertson's research on the presence of peroxide of hydrogen in secondary batteries is mentioned, and other parts of the book are equally well up to date, the experiments of Siemens and Swinburne at the Crystal Palace being described.

The most original portion of this thoroughly original book is the part devoted to Mr. Sprague's theory of current. His arguments were fully set forth in a discussion between himself and Prof. S. P. Thompson, which appeared in Vols. XXVI. and XXVII. of *The Electrician*. The summing-up of this discussion seems to show that Mr. Sprague prefers to explain phenomena of induction by "conditions of inductance and magnetance" rather than "a product of energy seeking dissipation in the 'medium.'" If he went no farther than this we should be disposed for the present to agree with him, since the magnetic explanation of electro-dynamics requires the fewest assumptions; but Mr. Sprague pushes the hydraulic analogy rather farther than that point which is commonly called orthodox.

A Dictionary of Electrical Words, Terms, and Phrases. By E. J. Houston. Second Edition re-written and greatly enlarged. (W. J. Johnston and Co., New York, and "The Electrician" Printing and Publishing Company, London.)

The fact that a second edition of this Dictionary has been called for shows that there is more use for it than would at first sight appear. Lawyers, for example, who have to "get up" an electrical case might find some reliable definitions and explanations which they could use with confidence without necessarily understanding them, but for students and persons engaged in electrical work it is not only better but necessary that they should understand the terms they have to use, unless they are of extraordinary rarity, such as "Isochasmen curves," which are drawn between zones on the earth's surface, having equal frequency of auroral discharges. The intelligent outsider may find this Dictionary of use if he desires to plunge into electrical literature, and it will be of value to those who are engaged in some allied science such as chemistry. The arrangement of the work might be considerably improved. Cross references are carried to a ridiculous extent, following each other continuously in some cases for several columns. To find the meaning of a "long shunt" we look in vain under "long," "shunt," "compound," or even "dynamo," but discover it under "machine." If the Dictionary were reduced by the omission of hundreds of unnecessary cross-references and such entries as the following, "Machine, Dynamo-Electric, to short circuit, a ..... To put a dynamo-electric machine on a comparatively small electric resistance," its usefulness would be increased. Magnetism is overdone; attempts are made to give digests of various theories. It is not the practice in American publications to place the illustrations in immediate proximity with the descriptive text, but this sensible plan has been followed, as a rule, in this Dictionary, and is to be highly commended. We notice, however, that an illustration of the Elihu Thomson meter is given under "Meter, Watt-," with a description of a dynamometer wattmeter.

MAGNETIC VISCOSITY.

BY J. HOPKINSON, F.R.S., AND B. HOPKINSON.

The experiments herein described were made in the Siemens Laboratory at King's College. The object was to ascertain whether the cyclical change in the magnetic induction in iron due to a given cyclical change in the magnetising force is independent of the speed at which the change is effected, that is, whether any sign of "magnetic viscosity" or "magnetic lag" can be observed when the rate of change is such as is found in transformers. The question is one of much practical interest, and has been much discussed, amongst others, by Prof. Ewing at the recent meeting of the British Association. Prof. Ewing has devised apparatus adapted to deal with this matter as well as for drawing curves of magnetisation.

We have experimented on two materials. One was soft iron and the other a hard steel containing about 0·6 per cent. of carbon. Both samples were supplied by Messrs. Richard Johnson.

It had been found, in experiments on ordinary transformers, that the local currents in the iron made it impossible to form a correct estimate of the magnetising force. The effect of such local currents can, of course, be diminished by using finer wire or plates and better insulation. Our material was in the form of wire $\frac{1}{100}$in. diameter, and the wire was varnished with shellac to insure insulation. It was wound into a ring having a sectional area of 1·04 sq. cm. in the case of soft iron, and 1·08 sq. cm. in the case of hard steel, and about 9cms. in diameter. The ring was wound with about 200 turns of copper wire, and with a fine wire for use with the ballistic galvanometer. An inspection of the curves showing the results will satisfy the reader that the effects of local currents were negligible.

For determining the points on the closed curve of magnetisation, given by rapid reversals of the current in the coil, the ring was connected in series with a non-inductive resistance to the poles of an alternate-current generator or a transformer excited by the generator, thus:—

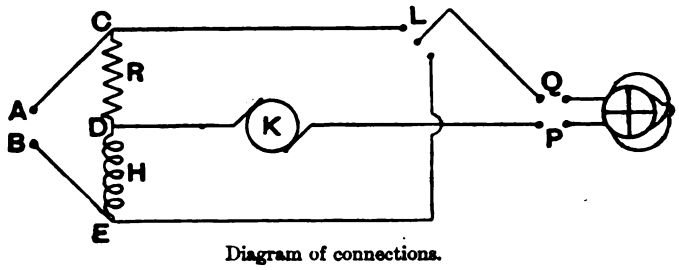

Diagram of connections.

in which A B are the poles of the transformer or generator, C D the terminals of the non-inductive resistance R, H the coil surrounding the ring, P and Q the studs of a reversing key connected to the quadrant of a Thomson quadrant electrometer, L a key by means of which Q could be connected with C or E at will, and K a revolving contact maker through which P was connected to D. A condenser was connected to P and Q in order to steady the electrometer readings. The contact maker K was bolted on to the axle of the generator. It consists of a circular disc of ebonite, about 13in. in diameter, having a small slip of copper about $\frac{1}{16}$in. wide let into its circumference. A small steel brush presses on the circumference and makes contact with the piece of copper once in every revolution. The position of the brush can be read off on a graduated circle, and thus contact can be made at any desired instant in the revolution, and that instant determined by means of the graduated circle. The quadrant electrometer thus gives the instantaneous value of the difference of potential between the points C and D, or the points D and E, according to the direction of the key L. The frequency was in all cases, except one, 125 complete periods per second. From observations of the values of the potential difference between C and D at different times in the period, a curve (A) was plotted giving the current or magnetising force in terms of the time; a similar curve (B) was plotted for the electromotive force between D and E. The curve (B) corrected by subtracting the electromotive force due to the resistance of the coil H gives the potential or time rate of variation of the induction in terms of the time. Hence, the area of B up to any point plus a constant, is proportional to the induction corresponding to that point. This is shown in curve C, which is the integral of B. A fourth curve D was then plotted in which the abscissa of any point is proportional to the magnetising force at any time (got from curve A) and the ordinate is proportional to the induction at the same time (got from curve C).

It is obvious that at the point where B cuts the axis the induction is a maximum; hence, if there were no "magnetic

Digitized by Google

lag" and no currents in the iron, this point should occur at the same time as that at which the current is a maximum. In the curves referred to this is seen to be nearly the case.

The slow cycles were obtained from the ballistic galvanometer, by observing the throw due to a known sudden change in the magnetic force. Care was taken always to take the material through the same cycle. The points got by the slow method are in each case shown in absolute measure on the same

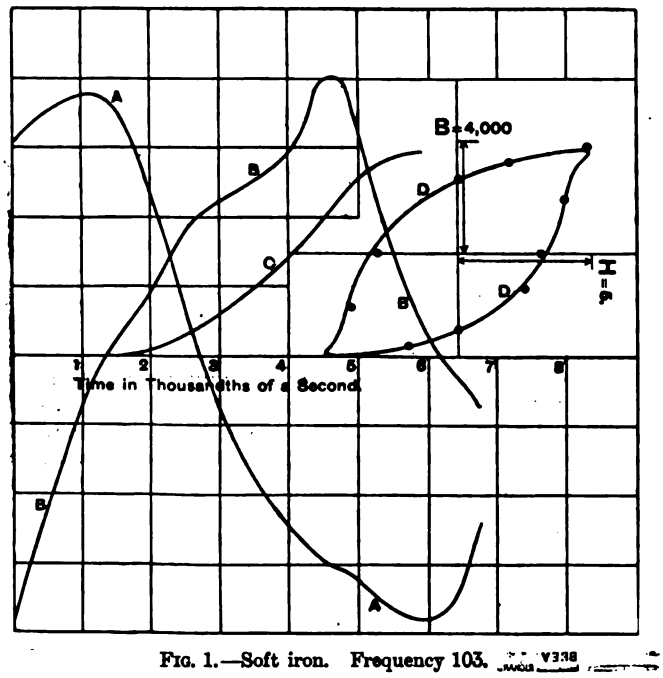

FIG. 1.—Soft iron. Frequency 103.

scale as that to which the quick curves are drawn, and are indicated by black dots; they are hardly numerous enough to draw a curve with certainty, but are ample to exhibit the identity of or the character of the difference, if any, between the curves, as determined by the two methods.

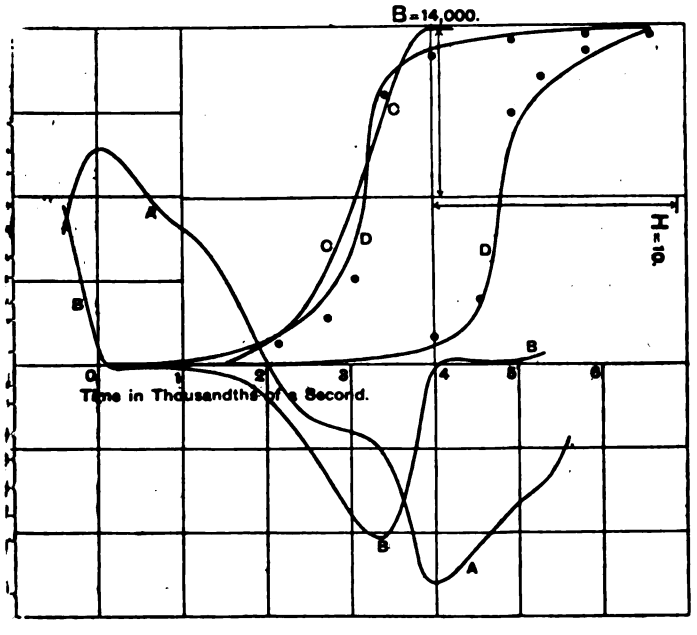

FIG. 2.—Soft iron.

Figs. 1 and 2 show the results of experiments on soft iron, Figs. 3, 4, and 5 were obtained from the hard steel. In all these the agreement between the slow and rapid cycles is fairly close. Fig. 6 is interesting, as showing the large effect of local currents. It was obtained from the same sample of steel wire as Figs. 3, 4, and 5, but the wire was *not* varnished. It will be seen that the maximum induction lags behind the maximum magnetising force about one-sixth of a complete period, and also that the maximum induction attained is but 10,000 as against 17,200 obtained from the same (apparent) magnetising force by the slow method.

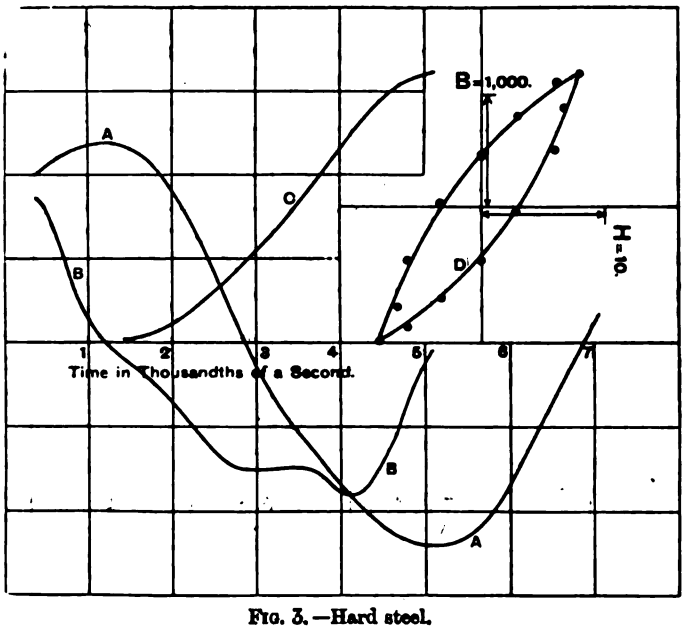

FIG. 3.—Hard steel.

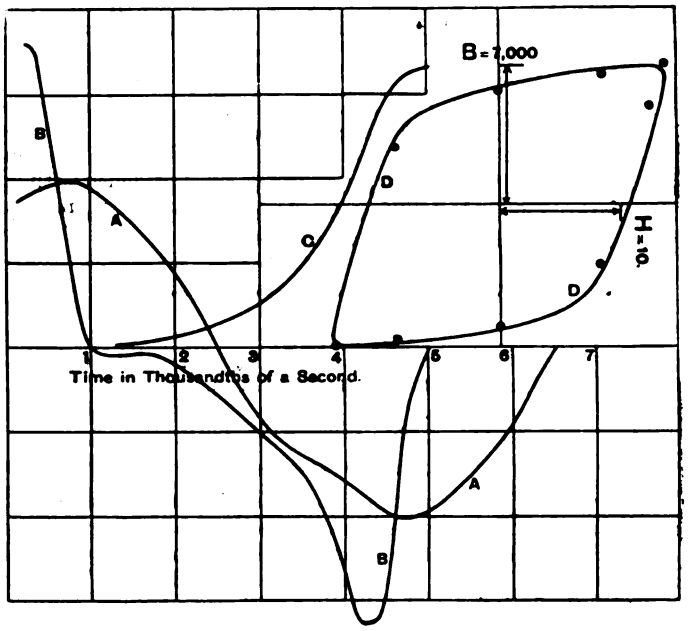

FIG. 4.—Hard steel.

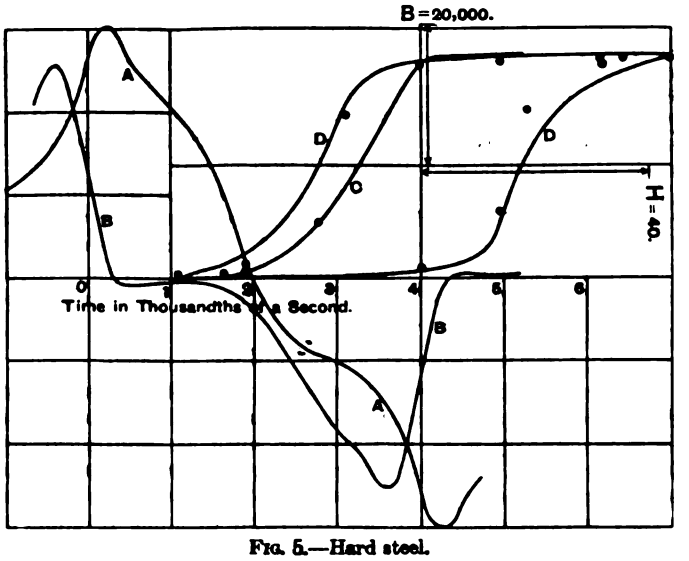

FIG. 5.—Hard steel.

Digitized by Google

Hence the general result is, that up to the frequency tried, *i.e.*, about 125 per second, there is no sign of magnetic viscosity; the magnetic cycle is unaffected by the frequency so far as the maximum induction for a given magnetising force is concerned; but that there is a sensible difference between the curve as determined by the two methods, most apparent in that part of the curve preceding the maximum induction. This difference

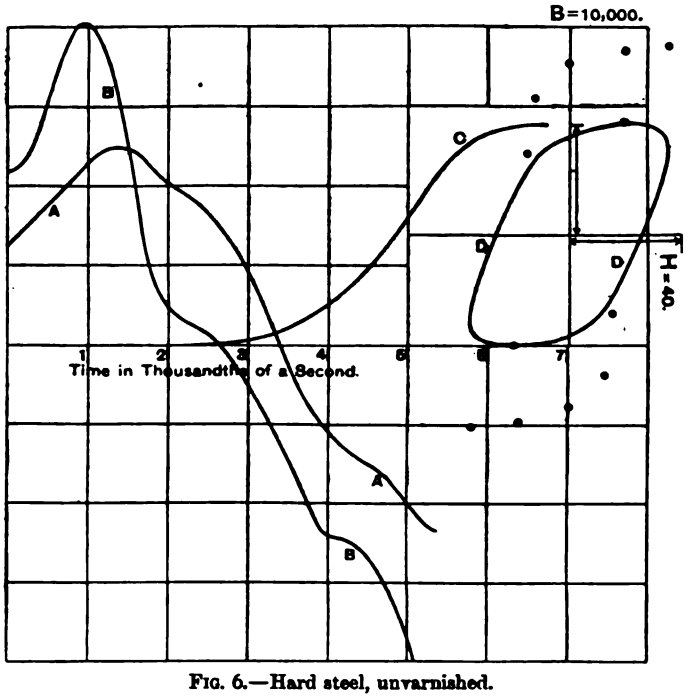

FIG. 6.—Hard steel, unvarnished.

is well shown in Fig. 5. We have not yet fully investigated this feature; possibly it arises from something peculiar to experiments with the ballistic galvanometer.

GEARING.

BY E. TREMLETT CARTER,

(Continued from page 455.)

Friction Pulleys.

The main objection to the two kinds of gearing which have now been described—belts and ropes—is that they require considerable, and in some cases impossible, amounts of floor space, owing to the long centre distances which must be given between the driving and following pulleys. A more compact form of gear is found in the friction pulley, in which the two pulleys, one of which is driving the other, are placed with their rims in direct contact.

When two pulleys are pressed together at their rims and one of them is set in motion, the other will be turned in a contrary direction with such a speed that the surfaces will roll over one another at the point of contact, provided the resistance to turning of the driven pulley is not greater than the friction at their contact surfaces. Power will thus be transmitted directly from the one pulley to the other. If P is the total pressure between the surfaces of contact measured normally to those surfaces, and μ is the coefficient of friction between the materials of which the surfaces are composed, then, since there is no fluid lubricant to modify the ordinary laws of solid friction, it is evident that:—

$P\mu$ = maximum resistance without slipping.

As it would obviously be unwise to allow the resistance of the driven pulley to become so large as actually to reach this limit in ordinary work, this product must be multiplied by some constant k (less than unity) depending on the materials of the pulley surfaces and on the conditions of working. In steady working, with materials not liable to suffer if slipping occurs at intervals, k may be taken at 0·9; whereas if sudden variations either in the driving effort or in the resistance are likely to occur, a lower figure must be taken. The power transmitted is therefore:—

$$\text{H.P.} = \frac{k.P.\mu.V}{33000} = \frac{\eta.k.\mu.P.D.N}{33000},$$

where D is the diameter of the driving pulley and N its speed in revolutions per minute.

It is found in practice that it is best to have one pulley surface of ordinary turned cast iron, covering the other with some material to increase the friction. Wood, millboard, gutta-percha and paper pulp are among the most common materials used for this purpose. It is found that the gearing wears best if the layer of extra material is put on the face of the driving pulley. This is most frequently the larger of the two pulleys. The following table gives the coefficients of friction, and the working pressure per inch width of pulley, for some of the most common materials working on turned cast-iron:—

Material.	μ.	lbs. per inch width.
Cast Iron	0·15 to 0·2	300
Wood	0·25 to 0·4	90 to 120
Millboard	0·20	100
Leather	0·3 to 0·4	100
Guttapercha	0·6	50 to 80

Wood is by far the most commonly used of these materials; oak, maple, beech and pine being the most serviceable. The crushing strength of timber is greatest if the fibres are set normally to the pulley face, but the coefficient of friction is least. It is usual to set the fibres parallel to the direction of motion of the rim—*i.e.*, tangentially along the rim.

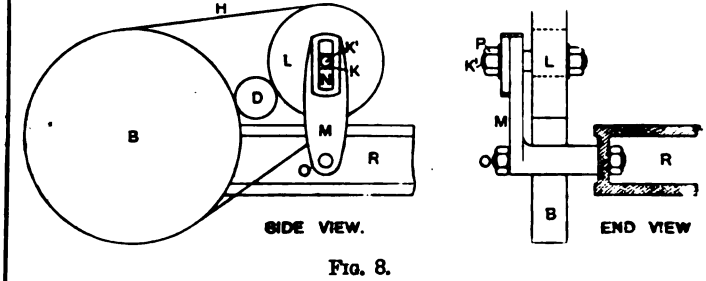

FIG. 8.

Owing to the very limited amount of pressure which can be put on the contact services of the pulleys, friction pulley gear will only transmit large amounts of power if the velocity of the rims is very high. It is clear that centrifugal force does not operate to reduce the power transmitted, as it does in flexible belt or rope gear, so that there is not the same objection to high peripheral speeds. It must not be forgotten, however, that, although this force does not reduce the friction, it sets up injurious stresses on the material of the pulley rims, both on the metal itself and on the band of wood or other substance covering it. At high speeds there is a liability on the part of the covering to strip off the pulley, and on the part of the pulley rim to burst. It is not advisable to use paper or millboard for velocities exceeding 5,000 feet per minute, and the usual practice with these rims is nearer 3,000 feet per minute; while, for wood blocks securely fastened into the pulley face, the speed should not exceed 6,000 feet per minute with cast-iron pulleys, and 7,000 with steel pulleys. These high velocities are more commonly met with in America than in England, steel pulleys being conspicuous by their absence in engineering on this side of the Atlantic.

An ingenious combination of friction pulleys and belt gear, the invention of Mr. Killingworth Hedges, is shown in Fig. 8. This consists of a driving pulley B, and a machine pulley D in frictional contact with it; while on the further side of D there is a larger idle pulley L, this being in frictional contact with D and in belt connection with B. Thus, when B turns, part of the power is transmitted directly to D by friction, and the rest through the belt to L, and then, by friction, to the other side of D; the side thrust of B on D being balanced by the opposite thrust of L on D. The centres are not exactly in line, and slackness in the belt is compensated by bringing them more nearly into line, thus increasing the centre distance between B

Digitized by Google

and L. This is done in the following ingenious manner:—The idle pulley L turns on a spindle K′ fixed to a block K. This block is capable of being raised or lowered in a slot N, by means of a set screw P, and by its position determines the degree of tightness of the belt. The slot N is cut in a lever M, which is freely pivoted at O.

Countershafting.

When a single engine is required to drive two or more machines, or whenever the velocity ratio between the engine and machine pulleys is too high for a single belt to be placed on both, some intermediate line of shafting, called countershafting, must be employed. The power is supplied to this shafting at a pulley, placed in connection with the engine by means of a belt or set of ropes, and is transmitted to other pulleys keyed on the shaft and driving the machine gearing. The shaft transmits the power by virtue of a torque which is set up, and the magnitude of this torque varies directly with the power and inversely with the speed. If T = the torque in inch pounds horse-power, the horse-power passing any section of the shaft, and N the revolutions per minute of the shaft, then—

$$T = \frac{63000 \text{ H.P.}}{N},$$

at this section. It will be observed that the torque is not necessarily the same at all sections; and that by a different arrangement of the machines it may be altered. Thus, if the power is supplied at the middle of the line of counter-shafting and distributed equally on either side, the torque will be only half that which would occur if all the machines were placed on the same side of the driving pulley. A smaller and lighter shaft, and one that will waste less power, will therefore be sufficient if the former arrangement is adopted instead of the latter. Again, by placing the heavy machines near the engine pulley on the counter-shaft, and the smaller machines further away, the efficiency of transmission is increased, since the power will have on the average to traverse less length of shafting.

The effect of torque on a shaft is to set up a shearing stress on every part of the section. If the section is circular, the stress on any part varies directly as its distance from the centre of the circle; so that the outer portion transmits much more power than the metal near the centre. The torque which any portion of the section will resist is equal to the product of the stress on that portion multiplied by its distance from the centre or axis of the shaft; and the total torsional resistance of the whole section is evidently the surface integral of this product over every portion of it. Thus, the resisting and power transmitting value of any portion of the material varies as the *square* of its distance from the axis of motion of the shaft. In hollow shafting only the more useful portions of the section are utilised, the central portions containing no metal. For the same weight of material a much stronger shaft is obtained; *i.e.*, the hollow shaft which will transmit the same power as a solid one, is, other things being equal, a lighter one. The extra expense of forging or casting a hollow shaft, however, renders its use prohibitive except for very large sizes. Ordinary countershaft is usually of solid circular section, and is made of mild steel or wrought iron. Cast iron was formerly used for this purpose, but with the introduction of higher speeds, and the consequent rapid variation of stress to which shafting was subjected, this brittle and unreliable material had to be abandoned. The maximum safe working stress to which these materials may be subjected in countershafting running from friction gearing is 13,000lb. per square inch for mild steel, and 9,000lb. per square inch for wrought iron. Toughness, to the extent of about 25 per cent. elongation before fracture, is a desirable quality in these materials.

Besides the necessary precaution of keeping the maximum stress on the shaft below the given limits, there is another important consideration. Under torsion a shaft is twisted through a certain angle, *i.e.*, the driving end is always a little angle ahead of the machine end. If this angle is allowed to exceed a certain figure, the shaft runs irregularly and vibrations take place. This is owing to the shaft catching, as it were, in the bearings, then slipping and catching again. The shaft gets twisted up till the torque is sufficient to turn it in the bearings, the friction diminishes directly motion takes place, the shaft consequently runs a little faster than the normal speed and slackens down the torque till it catches again, when the operation is repeated. The rapid repetition of this vagary causes unsteady and noisy driving, and can only be obviated by making the shaft stiff enough to limit the twist to a very small angle. In machine spindles and countershafts the amount of angular twist is about 1deg. for each length of shaft equal to 20 diameters. If a greater rate of twisting is permitted the driving is liable to be unsteady.

In Fig. 9, let r_1 represent any radius of the shaft which is twisted away from another radius r_2, with which it was formerly parallel, by the effect of the torque; and let $\frac{d\theta}{dl}$ represent the angular shear between them. Let E be the modulus of elasticity of the material, under shearing stress; and f the stress at the outer edge of the circle. The strain at the outer edge is—

$$\text{Strain} = r \cdot \frac{d\theta}{dl}.$$

And this bears a constant ratio to the stress, within the elastic limit; therefore,

$$E = \frac{\text{Stress}}{\text{Strain}} = \frac{f}{r \cdot \frac{d\theta}{dl}}$$

But, since the rate of angular twist is the same throughout the whole length of shaft,

$$\frac{d\theta}{dl} = \frac{\theta}{l}$$

From which

$$\theta = \frac{f \cdot l}{E \cdot r} \text{ in radians.}$$

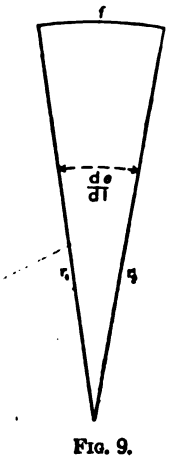

FIG. 9.

This shows that if we keep f within the safe working limits for all lengths and diameters of shafting, we must allow the angle of twist to vary directly as the length and inversely as the diameter. In practice,

$$\theta = \frac{l}{40 \cdot r} \text{ degrees,}$$

where l and r are measured in inches.

The amount of torque which is required to produce any given angular twist in a circular shaft varies directly with the angle and with the fourth power of the diameter, and inversely with the length. For mild steel,

$$T = \frac{34{,}300\, d^4 \theta}{360\, l} \text{ lb.-ft.} = \frac{34{,}300\, d^4 \theta}{30\, l} \text{ in.-lb.}$$

For wrought iron,

$$T = \frac{16{,}600\, d^4 \theta}{360\, l} \text{ lb.-ft.} = \frac{16{,}600\, d^4 \theta}{30\, l} \text{ in.-lb.}$$

Substituting the value of θ,

$$T = 686\, d^3 \text{ in.-lb. (mild steel),}$$
$$T = 332\, d^3 \text{ in.-lb. (wrought iron).}$$

Where, for convenience of working, d is taken in inches and l in feet. Equating this to the expression for torque in terms

Digitized by Google

of the power transmitted, which we deduced at the commencement of this article, we get—

$$683\ d^3 = \frac{63{,}000\ \text{H.P.}}{N},$$

or,
$$d = \sqrt[3]{\frac{93{\cdot}7\ \text{H.P.}}{N}}\ \text{(mild steel)},$$

and,
$$d = \sqrt[3]{\frac{190\ \text{H.P.}}{N}}\ \text{(wrought iron)}.$$

The margin that is allowed in the above rules for designing countershaft is ample; and no fear need be entertained that the material will be overstrained, provided only that the pulleys and bearing supports are properly arranged. Countershafting is subjected to bending action, in addition to the torsion due to the power transmitted. This bending causes a tensile stress on the material on the lower side of the shaft, and a compressive stress on the upper side, except in the case of overhung shafts, when the conditions are reversed. As the shaft rotates, the various portions of it are subjected to rapidly alternating stresses, each part coming under tension and then under compression in every revolution. This lively load is severe in its action, rendering toughness a necessary quality of the material, and causing deterioration in even the toughest and best qualities of iron and steel. The intensity of this stress depends on the rapidity with which it reverses, *i.e.*, on the speed of the shaft, and on the arrangement of the pulleys. By placing

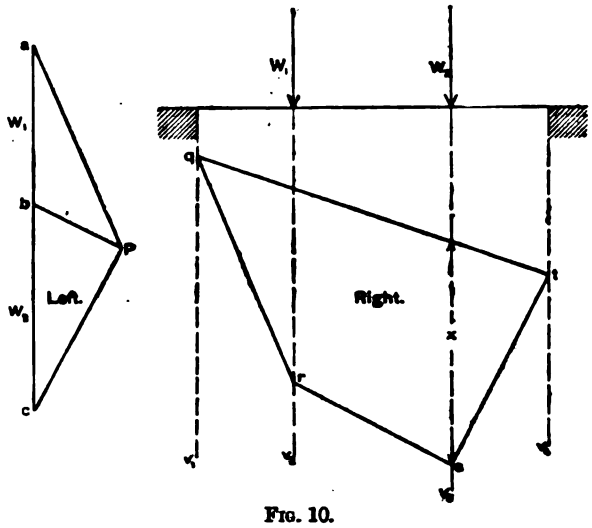

Fig. 10.

the heavy pulleys, and those on which the tensions of the belts is greatest, near the bearings the bending moment is made much smaller than if those pulleys are placed in the middle of a long span of shafting. Again, by reducing the distance between any two bearings, the maximum bending action on the section of shafting between them is reduced. It is the usual practice in fixing a line of countershafting to so space the bearings, and so arrange the pulleys, that the maximum bending moment shall not exceed the torsional moment; but the limit of working stress in the above formulæ will permit of a bending action equal to twice the torsion, in cases where it is impracticable to further reduce the bending.

The best method of estimating the distribution of bending action along a shaft is by means of Culmann's diagram. A scale drawing (Fig. 10, right) of the length of shafting between two supports, with the points of application of the several loads, is drawn to a scale of A inches to the foot; verticals V_1, V_2, V_3, V_4, &c., being drawn through the points of application, including the reactions at the supports. A stress diagram (Fig. 10, left) is drawn to the scale of B inches to the ton, commencing at the top with the left hand load and drawing lines *a b*, *b c*, &c., in the direction and order of the loads. A point, P, at a normal distance, C inches from the stress line *a c*, is joined to the points *a*, *b*, and *c*. Parallel to these, slanting lines are drawn in order, commencing with *aP* from the verticals V_1 V_2 V_3 and V_4, forming the sides of the polygon *qr*, *rs*, *st*; and the closing line of the polygon *tq* is then drawn. The lengths of vertical line included between the top and bottom of the polygon are proportional to the bending moments at the points on the beam vertically above. Thus, the maximum bending moment is at W_2, and is represented by the distance *x* included in the polygon. To find the bending moment in tons feet, the distance *x* in inches must be multiplied by the product *BC* and divided by the scale *A*, to correct for the reductions in scales. In this example the weight of the shaft has been neglected, but it is not usually safe to neglect it. A sufficiently near approximation, in the case of countershafting, can be made if the weight of the shaft is considered as a weight of half its value concentrated at the centre of the span; it may then be introduced into Culmann's diagram as a single additional load.

An examination of the diagram of bending moments will enable one to see that there is little or no bending action on the material of the shaft included in the bearings, while under the pulleys it is usually large. It is possible, therefore, to cut away the shaft to a smaller diameter at the bearings, thus reducing the loss of power on account of friction without seriously reducing the strength of the shaft. It is not possible to cut even a key-seat in the shaft under the pulleys without taking away active and necessary material; so that if the pulleys are to be keyed to the shaft by means of sunk keys, as is usually the case, account must be taken of this in selecting the diameter of the shaft, or a boss must be made on the shaft at the place where the pulley is to be keyed. The latter practice is adopted in the case of shafts of large diameter, as a shaft uniformly of the diameter under the pulleys would be too heavy and wasteful of power at the bearings; but with smaller sizes of countershaft, transmitting small amounts of power, it does not pay either to make bosses under the pulleys or to turn down the shaft at the journals. Some generating stations which pass considerable amounts of power through countershafting, such as at Taunton or at the Crystal Palace, use such large diameters of shafting that it pays to prepare it in the manner described; but, as a rule, countershafting is not used at all in large generating stations.

Countershaft Bearings.

There are several points to be observed by an electrical engineer in designing and setting up the bearings for a line of countershaft, and upon which the efficiency and regularity of running will greatly depend. The *bête noir* is undoubtedly the overheating and seizing of bearings, but there are minor troubles which can readily be avoided by judicious design and careful arrangement of the bearings. Rules are sometimes given to enable one to arrive at the proper distance between bearings; but all such rules which do not take into account the particular conditions of the gearing are misleading and dangerous. While 10ft. would be quite near enough in some cases, it would be much too long in others, even for the same size of shafting. The writer can think of no better rule than that which was adopted in the design of the shaft, viz., to keep the bending moment down to the value of the torque or thereabout. It must be remembered that with friction clutches in the shaft the bending action on the shaft when the clutch is out of gear is nearly four times as great as when it is locked and transmitting power; so that it will generally be found necessary to place the clutch close to one bearing if it is of small size, or between two bearings if it is of large size.

The number and position of the bearings having been determined, it will next be necessary to decide on the amount of bearing surface which each should have. To do this it is necessary to know the load on each bearing, which may be calculated or scaled off from Culmann's diagram of bending moments. The amount of surface for the brasses should be chosen with a view to getting only a limited amount of load on each square inch of surface. According to the so-called "laws" of friction, the friction ought to be independent of the amount of surface in contact; but, as a matter of fact, it is largely dependent upon it. A high-pressure squeezes out the lubricant from between the surfaces, and increases the coefficient of friction; while a low pressure renders a long bearing necessary, and increases the friction if the bearings are not in strict alignment. The amount of pressure which can safely be put on each unit of countershaft bearing surface is found to depend on

Digitized by Google

the viscosity of the lubrication and on the velocity of the rim of the shaft in the brasses. With high speeds, and with light oils, a small pressure only is allowable; while with heavy oils and slow-speed shafts a larger pressure is permitted. Since heavy oils are always used for slow speeds, and lighter oils for quick-running shafts, it follows that the amount of pressure which can be put on each unit of bearing surface depends only on the speed. The average pressure is 200lb. per square inch of axial section of the shaft included in the bearing; while for high-speed shafts the figure may fall to 100lb., and for low-speed shafts it may exceed 300lb. These figures relate only to countershafting. Bearing surface is measured as the product of the diameter of the journal into the length of shaft in contact with the brasses; or, as the axial section of the shaft. Therefore,

$$d \cdot l = \frac{P}{200},$$

where d is the diameter of the journal and l its length, in inches; and P is the load on the bearing in pounds. From this the *minimum* length of the bearing can be calculated. It may occur, however, that this length is small compared to the diameter of the shaft, owing to the load on that particular bearing being small; it will then be necessary to take a longer bearing. Countershaft bearings are usually from $1\frac{1}{4}$ to $1\frac{1}{2}$ times the diameter of the shaft in length.

The power wasted at the bearings depends on the size and distance apart of the pulleys. With all belts off, light mill-shafting wastes about 1 H.P. per 100ft. run; but crowded, heavy shafting, such as is used in electric light work, would probably waste between 5 and 10 H.P. per 100ft. under the same conditions. With belts on, the gearing should absorb not more than from 10 to 15 per cent. of the power supplied from the engine.

(To be continued.)

THE ELECTRIC TRAMWAY AT HALLE.

The Halle electric tramway is on the single overhead wire system. There are some steep hills on the route, which would necessitate the use of a third horse, if animal traction were used, but these are surmounted without difficulty by the electric cars. The power station, a general view of which is given in Fig. 1, contains three Steinmüller water-tube boilers having 1,520 square feet of heating surface each, and a grate area of 30 square feet, and are built for a pressure of 150lb. per square inch. Two of these boilers suffice for ordinary work, so that the third is kept as a reserve. Water is obtained from the town mains, but as it contains a large amount of alkaline matter it is passed through a Humboldt purifier before being allowed to enter the boilers.

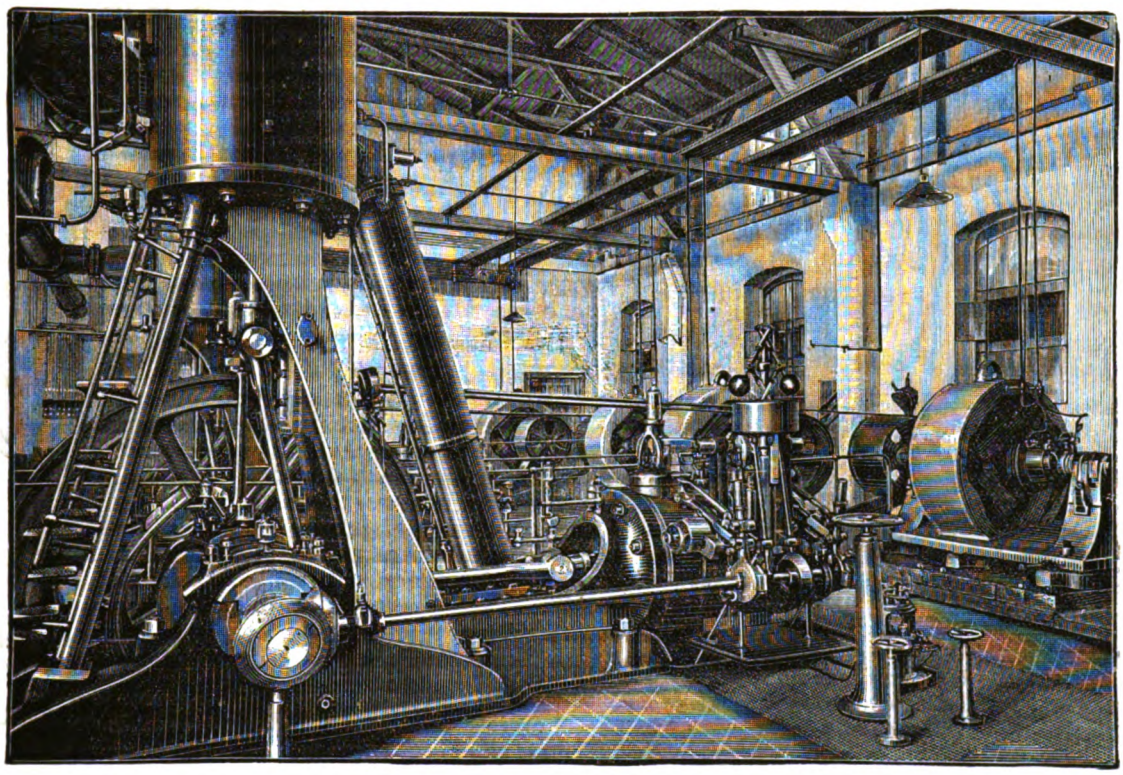

Fig. 1.

These boilers supply steam to two large engines built by the Gorlitz Machine Building Company. These are combined horizontal and vertical non-condensing engines. The horizontal high-pressure cylinder is 13in. diameter, 22in. stroke, and is furnished with Collman's valve gear. The vertical low-pressure cylinder is 21in. diameter and 22in. stroke. Each engine at the normal speed of 180 revolutions, with a pressure of 120lb., gives 125 effective horse-power, which can be increased to a maximum of 200 H.P. when the boiler pressure is raised to 150lb., so that either engine alone is capable of supplying the whole of the power needed for working the line. The valve gear works so satisfactorily that the same dynamo is used for lighting purposes whilst supplying power, and in spite of the high speed the engine runs quite steadily and without vibration.

The two engines drive, by means of belting, four dynamos, which, with all the rest of the electrical plant, were supplied by the Allgemeine Elektricitäts Gesellschaft. These machines are shunt wound, and give 500 volts 120 amperes at 520 revolutions. The poles of the dynamos are connected to two bars on the switchboard, one of which communicates by means of an insulated conductor with the overhead wire, whilst the other is joined to a naked cable leading to the running rails, and containing an ammeter reading to 800 amperes, and a main fuse. The main switch is on the overhead line lead, but each machine can be switched on or off the bars by a double pole arrangement. The regulation of the voltage is effected in the ordinary manner by an adjustable resistance in the shunt winding.

The arrangement of the overhead conductor is on a system introduced by the Allgemeine Elektricitäts Gesellschaft which is a modification of that of Sprague. It consists of two parts, the conductor proper and the working line. The former is insu-

Digitized by Google

lated and is partly above and partly below ground; in the former case it is suspended from poles, in the latter it is simply an armoured lead cable laid in the ground. In Halle it has a section varying from 50 to 95 sq. mm.

The working line is connected by cross wires at intervals to this conductor. In the present case it consists of a silicon bronze wire 6mm. ($\frac{3}{16}$in.) in diameter (about No. 4 B.W.G.). It is so stretched as never to come lower than 18ft. from the ground and is suspended in the narrow streets by light steel wires running from house to house and fixed to insulators, and in broader places by wrought iron poles. The iron poles have a cast-iron top in which a block of wood boiled in paraffin is fixed by means of sulphur, giving the line a double insulation. In some places two rows of poles are used with suspension wires passing between them.

A similar arrangement of suspension wires has to be adopted wherever curves, turn-outs, &c., occur throughout the track. Due provision has been made for the expansion and contraction caused by a range of temperature amounting to 130°F. The running rails, which form the return conductor, are bonded at the fishplates with a metal strip in the usual manner, and being of a heavy section, form a return of very low resistance.—

The line comprises three sections, having a total length of nearly five miles. The gauge is one metre, and the radius of the sharpest curve from 40 to 45ft. This necessitated a very short wheel base (about 5ft.). The current is collected from the working conductor by a trolley running on its under side, and supported by a steel arm pressed upwards by a spring, and carried by a flexible joint from the car roof. The motors, two of which are carried on each truck, are built by the Allgemeine Elektricitäts Gesellschaft, series wound for 500 volts at 1,150 revolutions. The carbon brushes require no adjustment when the direction of rotation is reversed. The arrangement of truck, including the method of suspending the motors, is that adopted in the United States by Sprague, whose German patents are owned by this Company. The necessary reduction in speed required to make the cars run at six miles per hour is effected through double-spur gearing, the wheels being of iron, and the pinions of aluminium bronze, with machine-cut teeth, and run in oil baths, being completely shut in by dust-proof boxes. A general view of the motor-frame is given in Fig. 2. Should either of the motors become defective it can be cut out of the circuit, and the car be worked by the remaining motor. Speed regulation is effected by changing the field windings, so as to avoid the use of wasteful resistances. The switch controlling this is actuated by an ordinary lever handle.

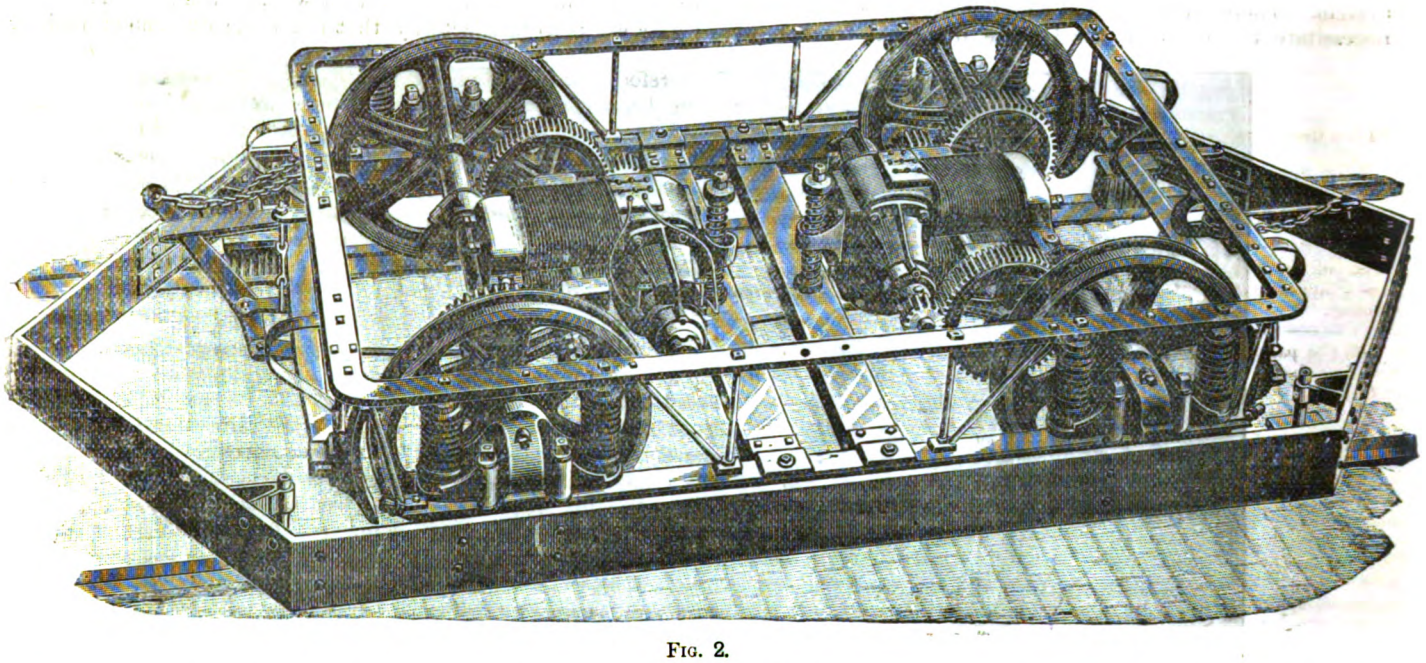

FIG. 2.

The rolling stock consists of 25 motor cars, and the same number of dummy cars, which at times of excessive traffic can be towed by the others. The introduction of electricity enabled a stud of 125 horses to be disposed of.

The cost of the entire equipment, including 25 electric cars, overhead conductors, buildings, &c., came to £30,000.

ON THE CLARK CELL.*

BY DR. KAHLE.

In connection with the Report of Mr. Glazebrook, I beg to call your attention to some researches I made, by order of the Physico-Technic Institute at Berlin, on Clark Cells. The time is too short for communicating my measuring methods and results in full extent; I can only give you a short summary of the chief points.

I used in my researches Lord Rayleigh's H form, the positive electrode being mercury once distilled, the negative an amalgam containing 90 parts of mercury and 10 parts of zinc. The last was filled in the vessel as a hot liquid, and solidified on the bottom. The paste, which covers the positive electrode, is made by grinding together mercurous sulphate, mercury, and a mixture of crystals and concentrated solution of zinc sulphate. No heat was used in preparing this paste. The mercurous sulphate was bought, and contained, according to chemical analysis, no foreign ingredients. The zinc sulphate was made basic by boiling with rods of metallic zinc; after cooling, the dissolved oxide of zinc precipitates, and with it the oxides of the metals more negative than zinc. For oxidising the ferrous sulphate, which is always present in commercial zinc sulphate, a small current was sent between two platinum electrodes through the boiling basic solution; the ferrous sulphate was changed by the generated oxygen into ferric oxide, and fell out. The H cells set up with these materials showed a great agreement in their E.M.F.'s; I never found a difference greater than $\frac{1}{10000}$th of a volt between the E.M.F. of any two of them.

The next point I studied was the influence of the impurities in the different materials composing the cell on the E.M.F., because on the one side it is well known that the smallest impurity of the mercury alters very distinctly the E.M.F., and

* Paper read before the British Association, in Section A, Edinburgh, August, 1892.

Digitized by Google

on the other side the mercurous sulphate I bought never contained impurities of a remarkable amount, and different samples always had the same qualities; I only investigated, as the most important matter, the impurities of the zinc and its sulphate. It was found that the foreign ingredients of the zinc sulphate are of very little importance, and that only the presence of free acid in the above-described cleaning process, the result of boiling with metallic zinc, alters the E.M.F. in a considerable degree. Among the impurities of the zinc only those caused by metals more positive than zinc are of importance; the zinc may contain considerable quantities of the negative metals without any alteration of the E.M.F. I suppose the impurities of the zinc are of greater importance. If we use it in the form of rods amalgamated on the surface, it seems to be a great advantage to dissolve the zinc in mercury, using it then as a solid amalgam.

The following are the values I found by a great number of observations for the temperature coefficient of different forms of cells, measuring between 10deg. and 30deg. in rising and decreasing temperature. The figures here given are the mean values of some cells of the same form, treated in the same manner:—

Form of the cell.	Temperature coefficient.	Mean difference between calculated and observed values of E.M.F.	Mean difference between the E.M.F. of the different cells and that of the mean of several H cells used as standards.
		The unit being $\frac{1}{10000}$ of a volt.	
H cell set up in Lord Rayleigh's manner.	+0·000812 + 0·000013 (+ − 15)	12	+ 3
H cell, the paste covering both electrodes.	+0·000774 + 0·000020 (+ − 15)	12	+ 7
A new form for research purposes, the paste covering both electrodes.	+0·000791 + 0·000017 (+ − 15)	9	+ 9
The cell issued hitherto by the German Reichanstalt.	+0·0·0806 + 0·000006 (+ − 15)	30	− 29

The mean value of the temperature coefficient, therefore, would be

0·000796 + 0 000014 (+ − 15).

Lord Rayleigh has given the following values for the two different cells he investigated:

+0·000827 + 0·000018 (+ − 15)
+0·000740 + 0·000016 (+ − 15)

the mean being

+0·000783 + 0.000017 (+ − 15).

I suppose, for practical purposes, the value found by Lord Rayleigh and by me are identical.

The most important matter is to obtain the absolute term of the E.M.F. For the purpose I used a measuring arrangement similar to Lord Rayleigh's. The current, which produces on the terminals of a known resistance a pressure equal to that of the Clark cell, was obtained by the silver voltameter. It was found that the same current deposits the more silver the more oxide of silver is dissolved in the solution of the nitrate. I made a solution of nitrate crystals, and boiled a part of it a long time with oxide of silver; the deposit gained with this basic solution was about $\frac{5}{10000}$ths greater than that with the original solution. Therefore, using a certain number for the equivalent of silver, there will be a little uncertainty of some parts of 10,000 in measuring currents by the deposit of silver. Now, as first shown by Prof. Schuster, and also proved by me by a good deal of experimenting, the deposit, when the voltameter is in vacuo, is about four parts of 10,000 greater than in ordinary air. But the absolute value of the E.M.F. is not touched by this fact, because making the electrolysis in this manner one has certainly to take a greater figure for the equivalent, and therefore the ratio between the unit and the measured amount of current remains the same. The following figures are given by taking one ohm = 1·063 S.U., and by assuming that a current of one ampere strength deposits in an hour 4·0259 grammes; the last figure exceeds that given by the Board of Trade only by six parts of 100,000. I found by some 30 experiments the E.M.F. of the H cells, set up with clean materials in the above-described manner, as 1·4332 volts at 15deg., and am sure that, when using the same arrangement of the silver voltameter, this value will be right by five parts in 10,000 if the equivalent is certain to this extent. If I express the value given by Lord Rayleigh for the cells of the original Clark's form in this unit, it is 1·4346 volts at 15deg. Lord Rayleigh finds the E.M.F. of this H cell a few ten-thousandths of a volt greater than that of the old form. Therefore it would, perhaps, be 1·4350 volts at 15deg.

Recently Mr. Glazebrook has made a new determination, and finds in the above fixed units as E.M.F. of the original Clark cell, 1·4342 volts at 15deg. He has also compared H cells set up by me and now brought to England, and finds their E.M.F. by $\frac{4}{10000}$ths of a volt smaller than that of the original form Therefore, the E.M.F. of the H cell is 1·4338 volts at 15deg. This last value and that found by me are in good agreement. It is remarkable that the anodes and cathodes in my voltameters are much smaller than those in the English ones.

It may be mentioned here that the mean E.M.F. of four H cells set up in the same manner as before, but containing, in accord with Prof. Carhart's directions, a solution of sulphate of zinc, saturated at 0deg., was found as 1·442 volts at 15deg, using the same units as above.

It only remains to give some directions on the best form of Clark cells. I suppose it will be good to distinguish such cells which are to remain as standards in the laboratories and are used by their maker, and such as are to be used for practical purposes. These do not need to have the same degree of accuracy, but they must be able to be carried about. In the Board of Trade memorandum, the original Clark cell is adopted as the standard; but I suppose Lord Rayleigh's H form gives more accuracy and is easier to set up. In the old form, not all the parts of the zinc rod are in saturated solution, and therefore the value of the E.M.F. will be a little uncertain. Another disadvantage is that parts of the zinc rod may fall down in the mercury, and will so produce a considerable variation of the E.M.F. On the other hand, the electrodes of the H form are always in concentrated solution, and there is no possibility of parts of the negative electrode coming over to the positive one. I have set up about 60 H cells, and have found no difficulty, when using carefully cleaned materials, to keep the difference of the E.M F. of the single cells under a ten-thousandth of a volt.

To construct cells for practical purposes which will stand carriage, the most simple way is to separate the two electrodes by a porous wall. I can show here such a cell of a form constructed by Dr. Feupner, and issued hitherto by the German Reichanstalt. The positive electrode is an amalgamated platinum plate with the surrounding paste in a porous vessel of clay. The zinc rod forming the positive electrode is on the upper part protected by a glass tube; the lower part is blown rectangularly and covered with crystals of sulphate of zinc. The whole glass vessel is filled with a concentrated solution of this salt. The E.M.F. of such cells is about $\frac{3}{10000}$ths of a volt higher than that of the H cells. The agreement of different cells of this form is very sufficient for practical purposes; the difference between the E.M.F. is always smaller than $\frac{1}{10000}$th of a volt. The only disadvantage of this form is that its E.M.F. does not follow quickly the alterations of temperature; but I suppose one could improve that by diminishing the size of the cell.

We endeavoured in the Reichanstalt to make Lord Rayleigh's H form transportable on account of its good qualities, and to do this without introducing foreign substances as porous walls. The investigations in this direction are not yet finished, but I can

Digitized by Google

show you here a cell which was constructed for this purpose and seems to be good. The positive electrode is formed by an amalgated platinum plate fixed on a wire of the same metal, which is melted in the bottom of one of the two tubes forming the vessel. The negative electrode is formed by the 10 per-centage zinc amalgam solidified on the bottom of the other tube, and also connected with a platinum wire melted in the glass. The whole vessel is filled with paste and closed by a glass stopper perforated by a thermometer, of which the bulb is within the vessel. Such a cell can be turned without any danger, and is suitable for transport. The E.M.F. is about $\frac{1}{10000}$th of a volt smaller than that of the H cells; the disagreement between the E.M.F.'s of different cells constructed in similar manner does not exceed $\frac{2}{10000}$ths of a volt. But before using such cells for practical purposes, they must be observed for a longer time till one is sure that their behaviour will not be altered by age.

These are the principal results gained during the last time in the Reichanstalt on this matter. Some of them will be already known here; but I hope to have given new proof that the Clark cell is a very accurate standard for E.M.F., and a good measuring instrument for practical purposes.

ELECTRIC HEATING AND SMELTING.*

BY STEPHEN H. EMMENS.

Newspaper readers have of late been frequently taught by their oracles that the day is close at hand when their houses will be warmed and their food cooked by electricity. And, even in technical circles, the phrase "electric smelting" is often used in a manner suggestive of some approaching industrial revolution. A plain statement of the facts and limits of the electrical heating problem in general may, therefore, prove useful.

One horse-power, exerted for one hour and completely converted into heat, is capable of raising the temperature of 645·85 kilogrammes of water by 1°C.=that is to say, 1 H.P.H=645,850 calories. One gramme of coal, if completely burnt, will yield heat sufficient to raise the temperature of 7½ kilogrammes of water by 1°C.—that is to say, the combustion of one gramme of coal generates 7,500 calories. There are 453·5926 grammes in 1lb. avoirdupois. Accordingly, 1lb. of coal will yield $7,500 \times 453{\cdot}5926 = 3,401,944$ calories, and 1 H.P. exerted for one hour is capable of the same heating effect as $\frac{645,850}{3,401,944} = 0{\cdot}1898$lb. of coal.

To produce by means of a steam engine one effective horse-power hour of electric energy, and to convert it into heat requires the combustion of about 4lb. of coal. Hence, to heat a room by means of steam-engine-generated electricity requires the consumption of $\frac{4}{0{\cdot}1898} = 21{\cdot}07$ *times as much coal as would be required by an ordinary stove.*

When I say that to produce, by means of a steam-engine, an effective horse-power of electric energy and to convert it into heat requires the combustion of about 4lb. of coal, I mean "to convert it into heat-output in a form available for heating buildings and the like, *i.e.*, into *radiated heat* emitted from the surface of an electric stove." Theoretically, if an electric current do no outside work it is *all* absorbed in heating the circuit, and in that case the efficiency of the apparatus (*i.e.*, the circuit) is the same as that of the dynamo; but where outside work is done by some apparatus included in the circuit the efficiency is the dynamo-fraction multiplied by the apparatus-fraction.

We know fairly well the apparatus fraction of an electric motor or transformer; but, as yet, no published data are available as to the proportion of current energy given off in the form of radiated heat from the surfaces of electric heaters. The only actual figures in my possession are those of a trial of two "Burton" and one "McTighe" electric stoves (car heaters) at Lincoln, Neb., last November. Mr. T. J. McTighe (of Barry and McTighe, electrical engineers), for whom I had conducted some preliminary experiments, sent me the figures. The trials were made by Mr. Francis Daniells, electrical engineer, and were carried out by enclosing the stove in a large box, and taking readings every ten minutes from a thermometer, the bulb of which was inside the box. It was considered that this showed the extent to which the internal atmosphere of the box was warmed by the action of the stove; but as the report is silent respecting any protective screen between the thermometer and the stove, I presume that the readings really showed the gain of heat on exchange.

* From the *Engineering and Mining Journal*.

The average result was as follows:—

	Rise per minute.	Electrical H.P.
McTighe	0·5°F.	0·605
Burton	0·4°F.	0·9045

The McTighe stove was composed of 3·3lb. of carbon rods having a radiating surface of 1·35 sq. ft. One horse-power minute is sufficient to warm 1lb. of water to the extent of 42·7°F. $\left(i.e., \frac{33,000}{772{\cdot}55}\right)$; so that 0·605 H.P. minute should produce a rise of 25·8335°F. in 1lb. of water. Taking the specific heat of carbon at 0·2, the 3·3lb. would require ·066lb. degree F. for a rise of 1 degree. Hence the 0·605 H.P. minute should have raised the temperature of the rods to the extent of $\frac{25{\cdot}8335}{0{\cdot}66} = 39{\cdot}14$°F. But the rise of temperature recorded by the thermometer was only 0·5 degree.

In view of this slow rate of rise, added to the fact that the thermometer-reading remained at times constant for a period of 20 minutes, and in view also of the probability that there could not have been any great waste of energy by heat-radiation from the external surface of the box, I conclude that the average rise of temperature as recorded may be taken as representing the average *available* rise of temperature of the carbon forming the stove. Hence the apparatus fraction of the McTighe heater was $\frac{·5}{39{\cdot}14} = 0{\cdot}0127$, and that of the Burton stove was obviously much less.

Another way of considering the test is as follows:—The difference between the actual temperature of the carbon rods and that recorded by the thermometer could not have been very great; for the reading at the expiration of the longest run (100 minutes) was only 117° F., as compared with 84° F. at the commencement. It is, therefore, reasonable to assume that the average difference of temperature between the stove and the thermometer was, say, 20° F. Now, according to Péclet, 1 sq. ft. of lampblack loses (or absorbs) radiant heat energy in one hour to the extent of 0·8196lb. degree Fahrenheit units for every degree Fahrenheit of difference between its own temperature and that of surrounding bodies. Taking this figure (obviously an excessive one) for the carbons with their surface of 1·35 sq. ft., the radiation per minute for every 1° F. excess of temperature will be $\frac{1{\cdot}35 \times ·8196}{60} = ·018441$ thermal unit; and for 20° F. excess, the emission will be ·36882 unit per minute. But the energy employed is ·605 H.P.=25·8335 thermal units per minute; and, therefore, the apparatus fraction is $\frac{·36882}{25{\cdot}8335} = ·0143$.

It may, however, be urged that the cost of electric heating should be compared with that of the usual method of steam heating, rather than with the more economical but less convenient stove and fire-place system. Let us make this comparison. One pound of coal burnt in the furnace of a steam boiler will convert about 9lb. of water into steam at a pressure sufficient for travel and utilisation in radiators, &c., and each pound of steam should deliver about 250,000 calories for warming purposes. Four pounds of coal, therefore, will, if employed in this manner, give out warmth to the extent of $4 \times 9 \times 250,000 = 9,000,000$ calories; whereas the consumption of the same amount of fuel for electric heating will give 645,850 calories. The electric heating system thus requires $\frac{9,000,000}{645,850}$ or 13·93 *times as much coal as is required for ordinary steam heating.* If the heat be required for smelting, the comparison must, of course, be made with coal or coke consumed direct.

It will probably be admitted that the figures above given are utterly prohibitory as regards any general introduction of electric heating or smelting, though for certain special purposes, such as railroad and street car heating, electric welding, the convenient localisation of high temperatures (*e.g.*, in the Cowles aluminum process) and the like, it may well be that the extra fuel cost of electricity is more than compensated by practical advantages not otherwise attainable.

But the question assumes an entirely different aspect in localities where water-power is procurable, and where fuel is scarce, as, for example, in the case of many mining districts. The cost of installing and maintaining a water-driven electric plant will be moderate, and although the effective output of heat at the point of consumption may still be a comparatively small fraction of the actual water-power employed, its raw material, so to speak, will be obtained without charge. It is in this direction that the next great industrial development of electricity may be looked for. The judicious utilisation of water-power will provide remote mining districts with *fuel*, in addition to mechanical energy and means of transportation, and will thus enable work to be carried on where otherwise all effective labour would remain impossible.

The use of electricity for the actual smelting of ores as distinguished from mere mechanical concentration may seem open to doubt. But it is certain that electricity may be made to provide *fuel* in the literal sense of the word, and fuel, moreover, of a cha

Digitized by Google

racter eminently suited for metallurgical operations. The decomposition of water by an electric current is nowadays a phenomenon of quite hoary antiquity; but the actual figures of the case are seldom borne in mind. Yet as 1 H.P. hour, if employed electrolytically, is capable of yielding 7½ cu. ft. of hydrogen and 3¾ cu. ft. of oxygen, it will be seen that practical quantities of reducing and oxidising gases may easily be obtained for use in furnaces or other metallurgical apparatus. It is true that the combustion of the 7½ft. of hydrogen would yield only 645,850 calories, or the equivalent of 0·1898lb. of coal; but the gaseous form of the fuel and its reducing character would render it vastly more applicable and effective. I therefore think it consistent with due sobriety of professional judgment to believe that by this method of utilising electricity many a mine may so far smelt its ores as to largely reduce the cost of carrying them to market, and may also successfully treat various classes of so-called "refractory" ores.

THE ELIHU THOMSON PRIZE.

At the last prize contest instituted by the City of Paris for the best electric meter, the prize of 5,000 francs was awarded to Prof. Elihu Thomson. With the desire that this sum should serve for the development of the theoretical knowledge of electricity, he has requested the general manager for Europe of the Thomson-Houston International Electric Company to offer a prize for the best work on a theoretical question in electricity, and to organise a committee who should propose the subjects, examine the productions, and decide the prize. The following gentlemen have been chosen, and have kindly consented to act as members of the committee:—J. Carpentier, Hippolyte Fontaine, E. Hospitalier, E. Mascart, A. Potier, examiner, B. Abdank-Abakanowicz, secretary of the committee. The committee has decided that the prize should be given for an investigation on one of the following subjects:—

1. The heat developed by successive charges and discharges of condensers under different conditions of frequency, nature of dielectric, and quantity of charge.

2. It has been shown theoretically that when the two surfaces of a condenser are connected by a conducting body, the condenser becomes the source of alternating currents as soon as the resistance of the conducting body decreases below a certain limit. The formula that permits calculating the period of this oscillation has not yet been completely verified. This period of oscillation should be investigated experimentally under conditions such that the exact measure of resistance, capacity, and coefficients of self-induction may be possible, in order to arrive at a complete and precise verification of this formula.

3. When a condenser made with an imperfect insulating material has been charged and then left to itself, the charge is gradually dissipated. The time necessary for the charge to be reduced to a given fraction of its initial value depends only on the nature of the insulating material. It is proposed to investigate whether, as certain recent theories would seem to indicate, analogous phenomena do not present themselves in metallic conductors, and whether these can be shown experimentally.

4. It is proposed to arrange and systematise our present knowledge of the graphical solutions of electrical problems, and deduce from them some general methods as in graphical statics.

The theses presented may be written in any one of the following languages: English, French, German, Italian, Spanish, or Latin. They may be in manuscript, or printed. Each thesis presented must be signed by a pseudonym and accompanied by a sealed envelope bearing the same pseudonym on the outside, and with the name and address of the author inside. The Papers must be sent before September 15, 1893, to B. Abdank-Abakanowicz, consulting engineer, the secretary of the committee, at 7, Rue du Louvre, Paris, who will furnish any further information required.

"Lava" Insulators.—"Lava," or, in other words, steatite, insulators appear to have obtained considerable vogue in the United States. This substance is, it is said, easily moulded and then hardened, and to be acid, water, and heat proof. According to a test made by the Thomson-Houston Electric Company, a cubic inch of steatite has a resistance of 50 megohms, which gives a specific resistance in C.-G.-S. units of $12{\cdot}7 \times 10^{16}$, as against $2{\cdot}27 \times 10^{16}$ for glass (at 200°C.), and $8{,}400{,}000 \times 10^{16}$ for mica.

ON A PROPERTY OF LAMELLAR BI-METALLIC CONDUCTORS SUBJECTED IN ELECTROMAGNETIC INDUCTION.*

BY CH. REIGNIER AND G. PARROT.

The electrical energy of a dynamo machine can be expressed by the following expression:—

$$W = 2\,H\,s\,N\,v\,\Omega\,\delta$$

where H is the average value of the maximum magnetic induction experienced in a revolution by any one of the armature coils of area s; N is the number of magnetic fields, alternately positive and negative, cut by a coil in a single revolution; v the number of revolutions per second; Ω the total section of the armature conductor; δ the current density.

The factors N, s, v, δ are independent of H. If H and Ω were also independent quantities it would be sufficient to give H a limiting value, and to go on increasing Ω in order to increase the available energy. But this is not the case; the magnetic induction depends on the length of the air path (occupied in actual machines by the armature conductors). The experiments of M. Leduc and the researches of the late M. Cabanellas showed that the magnetic induction measured in air varies sensibly inversely as the wave length of the lines of induction in air. Hence, since Ω is proportional to this air length, which has been called *entrefer*, the terms H and Ω vary inversely, and W remains constant.

If we substitute for the copper conductors ordinarily employed thin strips composed partly of a very magnetic and partly of a very conducting metal, placed so that the lines of induction are perpendicular to their thickness, the magnetic flux emanating from the north pole will divide into several bunches of parallel lines very close to each other, and traversing only the magnetic portion of the bi-metallic conductors. The higher the armature conductors are made the more the magnetic flux will tend to pass entirely through the magnetic portions of the strips. In other words, the magnetic induction is constant along the magnetic axis and the tube of force, which envelops the armature circuit, is cylindrical. The available energy in such an apparatus will increase sensibly in proportion to the height of the conductors.

We have constructed a machine based on this principle, and at 500 revolutions have obtained 32,000 watts. The total weight is 750kg., which gives a "specific utilisation" of about 42 watts per kilogramme of machine.

Our machine is not unlike a Faraday disc divided so as to guide the currents generated within it. In order to utilise all the space comprised in the circular crown subjected to induction the circuits consist of circular arcs. The winding is carried out as follows:—Two discs of a certain thickness are built up by means of a number of bi-metallic plates arched according to various radii. These are superposed, and the interior and exterior extremities are united so as to form a closed circuit by joining a plate of the first with one belonging to the second disc.

* *Comptes Rendus*, Vol. CXV., p. 310.

LEGAL INTELLIGENCE.

The St. Benet Fink and St. Nicholas Cole Abbey Faculties.

A sitting of the Consistory Court of London was held on Friday last week in St. Paul's Cathedral, before Dr. Tristram, Q.C., Chancellor of the Diocese of London, who delivered judgment in these cases as follows:—On Monday last, the 29th ult., application was made to this Court to authorise by faculty the construction of transformer chambers or vaults in two City churchyards long disused for burials—one in the churchyard of St. Benet Fink, close to the Royal Exchange, and the other in the churchyard of St. Nicholas Cole Abbey, in Queen Victoria-street—for the use of the City of London Electric Lighting Company (Limited), to enable the Company to introduce electric lighting into those parts of the City in which the churchyards are situated. The construction of these chambers will involve the disturbance of human remains, and their removal and reinterment in some other consecrated burial ground. . . . The church and site and the churchyard of St. Benet Fink were by a local Act of Parliament, 5 and 6 Vic., cap. 101, vested in the Mayor and Corporation of London, with a view to extend the avenues adjoining to the Royal Exchange. The Act provides that as soon as the "said church and burial ground shall be cleared, the same shall be enclosed by a substantial iron railing or other substantial fence, and the residue of the said site and burial ground shall remain for ever unbuilt upon and unappropriated to any purpose except such ornamental purpose. By this section the Court is precluded from dealing with the site of the churchyard, and by the Act the Corporation have now no power to deal with the vaults underneath the site, and the vaults being in consecrated ground this Court has jurisdiction to make such orders in relation to them as the circumstances of the case may require. The question is whether it has under the circumstances of this and the next case

Digitized by Google

discretionary power to make the orders asked for. The Commissioners of Sewers have granted permission for the erection of these chambers in narrow thoroughfares, but have refused permission in the present case, as its construction would disarrange the telephone and telegraph and gas and water companies' pipes; and, owing to the site required being a crowded thoroughfare, it would be for other reasons objectionable. The Company has also approached owners of adjoining property with a view to arrange for a sale of the site required without success. They have no compulsory powers to compel a sale of land for the purpose under their Act; and in the result, if this application were to fail, the area in question will remain unlighted by electric light. The petitioners have thus made out a strong case of urgency in the interests of the parishioners and public in favour of their application. It also appears that several applications have been made to the Company to light the City churches for Sunday evening services, which are well attended, and it is, therefore, against the interests of the Church that the scheme should fail. The Company also offer the payment of £25 to be appropriated towards the church expenses of the parish church. The special facts in support of the application in the case of St. Nicholas Cole Abbey are as follows:—The church and churchyard abut on Queen Victoria-street. Part of the churchyard was many years ago appropriated, under an Act of Parliament, for the construction of the District Railway. The chamber required cannot be constructed under the streets, owing to there being a subway for the supply pipes of the water and gas companies, and the Company have failed to acquire a site by private purchase. The proposed chamber will supply from 20,000 to 25,000 incandescent lamps, and there have already been applications for 5,000 lamps. The church is lighted with electric light, and the Company offer an annual payment of £30 towards the church services. If the faculty is refused the electric lighting of the church will cease. The question before the Court is whether it has a discretionary jurisdiction in the matter; and if it has, whether it would be proper exercise of it to grant the faculties prayed. The Court is of opinion that it would not be exceeding its jurisdiction in granting the faculties prayed, and that under the exceptional circumstances of these two cases it will be exercising a sound discretion in granting them. It therefore decrees the faculties as prayed—the faculties not to issue within 15 days, and advertisements to be inserted in *The Times* and *City Press*. So as to enable any members of families buried in the vaults to make application to me in chambers relating to their removal, a proviso will be inserted in the faculty permitting the removal of remains, if desired, by members of the families to any consecrated burial ground selected by them. The other remains will be removed to the parochial burial grounds of the respective parishes for reinterment in the consecrated portion of the cemetery.

Mr. Arnold Statham appeared for the petitioners.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 27, 1892.

Electrical Stocks.—The market for industrial stocks has been exceedingly buoyant for the past week on the exchanges in both Boston and New York. The stocks of nearly all electric companies are quoted at higher prices than at any time during the year. Westinghouse stock, for instance, has been continually advancing until it reached 40 in the Boston market yesterday afternoon. This is the highest point at which it has been sold since the financial difficulties which brought its stock to the lowest point it ever sold, that is 7 on a par value of 50. The Wall Street *Daily Bulletin* is authority for the statement that the proposition which was made by the General Electric Company to purchase the Westinghouse stock was on the basis of $30 for the common and $50 for the preferred, both stocks being par at $50. This proposition was declined as being too low, and it is understood that before long another offer will be made in which the price offered will be increased. This was mentioned in a former letter as likely to take place immediately after the decision in the Court of Appeal on the Edison incandescent lamp patent is handed down. This is expected early in the fall, and no one doubts that it will be in favour of the Edison Company, which, under the present management, of course means in favour of the General Electric Company. The General Electric stock, of which the par value is $100, was quoted on the Boston exchange at $117½.

Niagara.—Prof. W. C. Unwin and Prof. Geo. Forbes, of London, met on the 22nd at Niagara Falls with the Cataract Construction Company to discuss the ways and means pertaining to the projected transmission plants on the American and Canadian sides of the Falls. The proposed construction of the Canadian tunnel was given definite form by investing Prof. Unwin with the necessary authority to prepare plans for the projected tunnel. This is to be 800 feet long, and will, therefore, not occupy any extensive amount of time in its construction. When the two tunnels are finished it is proposed to have the transmitting system of the one side connect with that of the other so that in case of any breakdown current may be transmitted by the other. It is stated that Profs. Unwin and Forbes will remain at the Falls for a week or more looking after the work of the project, which is now well under way.

Sales at Chicago Exhibition.—Concerning the sale of merchandise at the World's Fair, Secretary Crawford, of the Exposition Committee on Ways and Means, has written a letter, which very fully covers the subject. The following is an extract:—

> The sale of goods for immediate delivery and consumption will be prohibited in all the buildings except where concessions or privileges are specifically given on the merits of the individual cases, but no concessions will be granted for general merchandising either within the buildings or within the grounds of the Exposition. The exception treated of refers especially to Oriental goods, and such natural curiosities as are peculiar to the countries and sold by the natives of such countries. The Exposition even proposes to restrict the sale of these natural curiosities, as if the door is open which will permit general sales of this kind the bazaar feature will easily and quickly develop. The exhibits may be used as samples from which orders may be taken and filled from a depôt or storehouse either outside the grounds, in Chicago, or from the home office of the exhibitor. This is a matter over which the Exposition cannot exercise any jurisdiction, and it therefore claims no authority whatever.

Electric Traction in New York.—A very important franchise was granted last week to the Union Railway Company, a concern which is to control and operate an extensive system of electric railways in the upper part of New York City, commonly called the Annexed District by city residents. An idea of the size and importance of the system may be gained from the fact that the franchise granted specifies that the Company's payment of revenue to the city is not to begin until the daily revenue is $1,700, and it is expected that this provision will exempt the Company from taxation for ten years; in other words, the system as at present planned is expected to bring the Company a daily income of $1,700 at the end of about ten years. It is provided that when the income amounts to this figure the Company is to pay into the city treasury 1 per cent. of its earnings, and that when it amounts to double this figure the Company is to pay 2 per cent. A great deal of opposition has recently been manifested in and around New York City to the overhead trolley system, and it was quite a surprise, even to the friends of the trolley, to find that a franchise of so great importance had been granted to advocates of the overhead system within the city limits. This is regarded as second in value to the Broadway franchise of New York City.

American Association for the Advancement of Science.—The American Association for the Advancement of Science held an interesting meeting at Rochester, N.Y., beginning on Wednesday, August 17th. This was the forty-first annual meeting of the Association, and was quite largely attended, although it is by no means as important a meeting among American scientists as the British Association is among the scientists of Great Britain. The electrical subjects come up for discussion in the section devoted to physics as well as in that devoted to Papers on mechanical and engineering topics. Prof. Ed. B. Rosa, of Wesleyan University, Middletown, Conn., presented an interesting Paper on electro magnetism. Prof. A. E. Dolbear, of Tuft's College, exhibited some models designed to illustrate electro-magnetic relations. Prof. Whitman, of Adelbert College, read a Paper on magnetic disturbances caused by street railway currents. Mr. Chas. B. Thwing read a Paper on a photographic method of mapping the magnetic field, and Prof. Whitman, in the physical section, read another Paper on the constancy of volume of iron in strong magnetic fields. Prof. E. L. Nichols, of Cornell University, read a Paper on the distribution of energy in the spectrum of the glow lamp, while Prof. B. W. Snow, of Bloomington, Ill., read one on the distribution of energy in the arc. One of the most interesting Papers, electrically speaking, was one by Prof. J. E. Kershner on electric lights for astronomical instruments.

CORRESPONDENCE.

ELECTRICAL TRACTION AND COVERED CONDUITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to your remarks last week on above, in justice to others as well as to myself, allow me to give the following facts:—

That iron had been used to cover a conduit half a century ago is true, but I do not think it was ever in the form of a strip, either continuous or free. It was a compound construction of leather and hinged flaps. Moreover, the object was entirely distinct from the present. It was to make an air-tight or water-tight joint along a pressure main on a railway. Even the description of this as a rope valve conveys a wrong impression, as it is fastened all along one edge. A real rope valve has, however, been suggested for this purpose in a publication by Talbot and Hiddiard many years ago; but it is a distinct idea to utilise any such class of opening for a modern electric street conduit, though the speed of 60 miles an hour, at which they were successfully worked, gives a good idea of its practicability. Since instituting my researches and practical experiments I discovered that I cannot take credit even for this idea. Patents have been issued in the United States to Blake for a strip of rubber laid on a bare conductor, and set on the road surface, the strip being free and raised by stretching it sufficiently for a pulley to run underneath. The intended object of this inventor, as stated in his patent, was to avoid the use of a chambered conduit with the conductors supported inside.

Now this we know is the only practical way of using a bare conductor in a street conduit, for the leakage throughout any such system as Blake's would be inadmissible. This was recognised by Chas. W. Van Depoele, who soon followed with the chambered conduit, having rubber or other insulating soft cushions on each side of the slot, which were wedged open by the connecting conductor travelling with the car. Prof. Elihu Thomson, evidently seeing the weakness of such cushions, changed them for a number of stout fibres like a brush.

Neither of these, however, fully answered the requirements, they do not seal the conduit enough, they have no transverse strength, and therefore could not be used to cover a wide opening, which is the most necessary thing of all to obtain success. Even were the Blake or old rope suggestion used in my system with the chambered conduit, the want of transverse strength, the bad fitting, the liability to wedge down, and the deterioration of the material, would make them useless. There are many other points, notably at the crossings and turn outs, which make the construction of a number of bars of metal or equally hard substance connected by sliding joints into a continuous strip or rail, the only practical and workable article that any experienced man is likely to recognise for this work.

I do think that "this mode of protecting a covered conduit" is entirely and valuably original, if only from the American legal point of distinction that it makes of commercial practical value a thing already known, but the fact that patents are now granted nearly all over the world, including the most careful and Conservative Government offices, best attests to its true originality.—I am, Sir, &c.,

Britannia Works, Helsby. CARL T. B. BRAIN.

[Mr. Brain need hardly concern himself about the Clegg and Samuda closed conduit as an anticipation of his patent. We merely described this old invention as a curious coincidence, and an example of history repeating itself.— ED. *E.*]

HIGH VOLTAGE LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your Notes of September 2nd you refer to Messrs Khotinsky as if they were the only makers of high voltage lamps, whereas we have been making them for several years; and during the last six months we have made considerably more than 10,000.

I quite believe that credit is due to Captain de Khotinsky of being one of the first to commence the manufacture of these lamps commercially, but where there is a demand manufacturers are seldom wanting, and the whole question is simply one of economy.

Briefly stated, the scientific efficiency or economy of a lamp is the total useful candle-hours, as compared with the total energy or watts consumed; whereas the commercial efficiency, or economy, are those two factors, *plus* the cost, not only of the lamp itself, but also the trouble of replacing it when broken, and the cost of supplying energy to it.

Captain de Khotinsky very correctly points out that these lamps cannot be made for the same price as ordinary lamps, and I doubt much whether the 25 per cent. extra charge is really sufficient to pay the makers considering the small demand.

A central station man can easily see if 25 per cent. extra in the cost of lamps will be compensated by the further economy in conductors which is a simple case of interest on the copper used in them.—Yours, &c., C. FARADAY PROCTOR.

Ingénieur et Chef de fabrication, Cie. Gle. des Lampes Incandescentes (Edison and Swan), Paris.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—Our advertisement columns contain an announcement that the Board of Lighting Inspectors for Chertsey are prepared to receive proposals for lighting the district with electricity. Particulars can be obtained of Mr. E. H. Gale Crowdy, Clerk to the Board, Chertsey.

———— Messrs. George Angus and Co. (Limited), Dale-street, Liverpool, invite tenders for various railway stores, including 20 tons of galvanised telegraph wire, 100 tons of galvanised iron, 22 tons of zinc, &c. Tenders are to be in by noon on Monday, the 19th inst.

TENDERS ACCEPTED.—The Hanley Town Council on Tuesday accepted the tender of the Brush Electrical Engineering Company (Limited) to light the town by electricity, the amount of the tender being £15,760.

———— The Dolgelly Local Board have accepted the tender of Mr. Hall, of Liverpool, to light the town by electricity during the coming winter for the sum of £80.

————. The Uxbridge Local Board have accepted the tender of Mr. G. Jennings, of the Stangate, Lambeth, for providing and fixing complete an electrical tell-tale with electrical appliances and underground wire between their waterworks and reservoir, 1¼ miles apart, for the sum of £84. 15s.

————. The tender of Messrs. Blaikie Brothers (Limited), Aberdeen, has been accepted to supply girders for the Dundee electric lighting station at £224.

————. The Electric Lighting Committee of the Derby Corporation have accepted the tender of Messrs. G. Fletcher and Co., of that borough, for the supply of boilers and accessories for the electric light station.

TENDERS RECEIVED.—The following tenders have been received from Newcastle firms for the plumbing, gas-fitting, and electric light work in connection with the re-building of an inn and some warehouses in Newgate-street, Newcastle-on-Tyne:—

	£	s.	d.		£	s.	d.
Emley and Sons	550	0	0	J. Somerset and Co.	475	0	0
C. Patterson	527	0	0	W. Burn	466	16	0
A. Scott	506	5	8	R. Herron	460	9	8
H. Walker and Co.	499	4	0	H. Simpson	450	16	9
E. Johnson and Co.	492	0	0	Bland Bros.	445	0	0
Threlkeld and Wallace	490	8	0	R. J. Charleton and Co.	440	0	0
J. France	481	10	0	M. Gibson (recvd. too late)	485	0	0

ABERDEEN.—The Aberdeen Town Council resolved on Monday to proceed with the private lighting of a certain district of the town by electricity. The Council propose to undertake the work of supplying electricity, the estimated cost of the undertaking for the limited portion of the city being £24,460.

BELFAST.—It was announced at the meeting of the Belfast Corporation on Thursday that the Gas Committee had resolved to recommend the outlay of £300,000 to supply the electric light for the centre of the city.

BLACKPOOL.—The Town Council on Tuesday resolved to purchase the electric tramways in the borough for the sum of £15,750.

DUNDEE.—The Secretary of State for Scotland has sanctioned the raising by the Gas Commissioners of a loan of £20,000 for the execution of works under the Dundee Electric Lighting Order 1890.

Digitized by Google

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—Under the management of Mr. C. M. Downie, the Edison and Swan Company have opened extensive show rooms and warehouse at 110, Cannon-street, London, E.C., where a large stock of every variety of Edison and Swan incandescent lamps, from 2½ to 1,500 c.p., will be on sale. We understand that arrangemen's have been made for stocking not less than 20,000 lamps in these City premises, which have been opened to meet a large demand in the E.C. district. In addition to the special manufactures of the firm in incandescent lamps, a large display of the latest designs in lamp fittings, shades, and globes will be on view, as well as some special designs in electroliers and ships' fittings. Casings and electric light cables are to be a special department of the new show rooms, and included in the stock already showing are many handsome designs in bracket lamps and electroliers. Provision is made for the stocking of a limited assortment of switch boards and Cardew measuring instruments, and a quantity of various styles of the well-known "Tumbler" switches, lamp holders, suspender lamps, small incandescents for medical and similar purposes, and all kinds of supplies for electric lighting installations. A choice selection of out-door designs for the illumination of winter gardens and similar displays can be seen, and a large variety of incandescents in all colours and shapes will be obtainable for table decorations and "occasional" installations. The new premises occupy 100 feet frontage, 50 feet of which is in Cannon-street, and doubtless, owing to the central position of these show rooms and offices, a large additional business will result. The show rooms are neatly wired; the casings forming a part of the ornaments of the ceiling and wainscots. The large quarto catalogue of the Edison and Swan manufactures, with which many of our readers are familiar, can be obtained on application.

MADRID.—The Royal palace is lighted by gas made on the premises, but instructions have been given to instal the electric light. Some 1,800 lamps will be required, and the estimates sent in range from £14,000 to £20,000.

TAUNTON.—A petition has been forwarded to the Board of Trade by several ratepayers asking the Board to refuse its consent to the proposed purchase by the Town Council of the electric light works, plant, &c., of the Taunton Electric Light Company for the sum of £9,300. The petitioners say that the Town Council decided on the purchase, notwithstanding the adverse report of an expert electrician called in by them, and that the acquirement and extension of the works, &c., would result in a dead charge on the rates of nearly £2,000 per annum. The Laing, Wharton and Down Construction Syndicate (Limited) have addressed a letter to the Town Clerk of Taunton asking to be kindly furnished with the names of the valuers suggested some time ago by the Board of Trade for the purpose of valuing the electric light works, in addition to that of Mr. Gisbert Kapp. TheSyndicate also offer to bear the entire expense of another valuation.

COVENTRY ELECTRICAL ENGINEERING COMPANY.—We are asked to state that owing to increase of business this firm have taken larger premises situate at Ryley-street, Coventry. Mr. W. J. Butlin has recently joined the firm.

SUNBEAM LAMP COMPANY (LIMITED).—This Company announce that although they have temporarily ceased the manufacture of the "Sunbeam" lamp, they are still supplying their patent "Sunbeam" holder, which they claim to be the best, simplest, and neatest holder in the market for large incandescent lamps. They further say that the Edison and Swan United Electric Light Company (Limited), to meet the growing demand for "Sunbeam" holders, are now making lamps to suit these holders.

WIRING TABLE.—We have received a copy of Messrs. Walter T. Glover and Co.'s new wiring table. It gives all the figures and formulæ likely to be of use to an electrical engineer in calculating the best size of wire to be used in house conductors or street mains. There is a column showing the safe carrying capacity of the wires with a current density of 1,000 amperes per square inch; this allows an approximate loss of 2½ volts per 100 yds., and thus facilitates calculations.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—With the appropriate heading of "Are you there?" this Company issue an illustrated pamphlet calling public attention to the advantages of the telephone for a number of useful purposes. Commencing with the domestic telephone, the pamphlet deals with the advantages the instrument offers to proprietors of hotels and boarding houses, theatres and other places of public entertainment and amusement, churches and chapels, offices and works; for military and naval purposes, in mines and collieries, &c. The Company claim for their instruments that they are superior in manufacture and thoroughly reliable. For use in mansions and private houses, the cabinet work can be supplied to harmonise with the surroundings. Tradesmen who instal the Company's instruments would do well to obtain a supply of these pamphlets for probable customers.

ELECTRICAL INSTRUMENTS.—We have received from Mr. R. W. Paul, of 44, Hatton-garden, a new catalogue of electrical instruments. Several of these have been recently described in our columns. Among his specialities are a flat resistance coil allowing a definite temperature to be quickly arrived at and measured; resistance boxes, the coils of which are put in circuit by plugs connected to stout flexible cables; variable carbon resistances; Ayrton-Mather and other galvanometers.

THE SILVERTOWN COMPANY.—This Company have issued their revised list of particulars and prices of the various kinds of Leclanché battery made by them. The list is illustrated.

THE CHILI TELEPHONE COMPANY (LIMITED).—This Company has recently obtained an important concession from the Chilian Government, whereby the latter binds itself to use the Company's telephones in all the public offices to the exclusion of all other systems. The contract is to remain in force for ten years, and the rates paid are to be the same as those actually ruling, but subject to certain modifications dependent upon the rate of exchange. In return the Company is under an agreement to expend the sum of £30,000 within the next few years in improving its installations and plant.

MESSRS. A. HALL AND CO.—This firm have installed the electric light on the premises of Mr. W. Boote, furniture storer, Elizabeth-street, Liverpool. There are forty 16 c.p. incandescent lamps, and a 3,000 c.p. arc lamp within and without the building.

MESSRS. F. C. ROYCE AND CO.—This firm have recently put down an electric lighting plant at the Stanley Colliery, Derbyshire.

POOLE AND WHITE (LIMITED).—A petition for the compulsory winding up of this Company was presented on the 1st inst. by Mr. L Hervé, 90, Clerkenwell-road, and is down for hearing on Wednesday next, the 14th inst.

HENLEY TELEGRAPH AND ELECTRIC CONSTRUCTION COMPANY (LIMITED).—A petition for the winding up of this Company was presented on the 23rd ult. by Mr. A. P. Matheson, merchant, of 9, Cornhill, E.C., and is appointed for hearing on October 25th.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "The Electrician" Electrical Trades' Directory and Handbook, 1892, pages 308-322, *&c., &c.*

ADOLPH CROSBIE (LIMITED).—This Company has been registered with a capital of £15,000, in £5 shares, to carry into effect an agreement for the acquisition of the undertakings of the Red Oxide Company, and of the Cheshire Carrying Company, hitherto carried on at Wolverhampton and elsewhere, and to develop and turn to account the same.

C. AND E. GRAY (LIMITED).—This Company was registered on September 1st, with a capital of £5,000, in £5 shares, to carry on the business of brassfounders, cabinet brassfounders, and ornamental metal workers carried on by Charles Gray and Edwin Gray at Exeter-street, Birmingham.

EMILE LANSARD SYNDICATE (LIMITED).—Registered on August 23rd, with a capital of £10,000, in 400 Six per Cent. Cumulative Preference, and 1,600 Ordinary Shares of £5 each, to acquire the business of engineering machinist, general press and press tool maker and dealer in and manufacturer of stamped and pierced metal goods and electrical fittings, carried on by Emile Lansard, at 216, Goswell-road, London, E.C.

NOTTINGHAM MACHINISTS' COMPANY (LIMITED).—This Company was registered on September 1st, with a capital of £30,000 in £1 shares (of which 30 are founders'), to carry on the business of cycle manufacturers and otherwise, carried on by a Company of the same name at Ilkeston, Derbyshire, and to carry on the business of manufacturers of and dealers in, and to buy, sell, let on hire, and repair, every description of apparatus and appliances required for or capable of being used in connection with the generation, distribution, supply, accumulation and employment of electricity, and generally to carry on the business of electricians and engineers in all their branches.

MISCELLANEOUS.—Bedson Wire Company (Limited), wire drawers and wire manufacturers; capital, £50,000, in £100 shares.——Carboid Oilless Bearing Company (Limited), owners of patents and inventions relating to the manufacture of carboid; capital, £2,000, in £1 shares.——New Weighing Machine Company (Limited), makers of weighing machines, electrical engineers, &c.; capital, £20,000 in £1 shares.——Robert Dempster and Sons (Limited), gas, chemical, and hydraulic engineers; capital, £3,000, in £10 shares.

ELECTRIC FITTINGS HIRING AND MAINTENANCE COMPANY (LIMITED).—The statutory return of this Company, made up to February 23, 1892, was filed on August 15, 1892. Out of a capital of £200,500, divided into 40,000 ordinary shares of £5 each, and 500 founders' shares of £1 each, seven shares have been taken up, but no calls made. The original signatories to the Memorandum of Association are the only shareholders.

GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).—The annual return of this Company, made up to August 9, 1892, has been filed. The Company was registered on July 11, 1873, with a capital of £3,000,000, in £10 shares, and since that time the capital has been raised to £5,000,000, divided into 250,000 ordinary and 250,000 preference shares of £10 each, 180,227 ordinary and 180,042 preference shares have been taken up, the full amount called, and all calls (£3,602,690) paid.

RUSTON, PROCTOR, AND CO. (LIMITED).—The annual return of this Company, made up to June 14th, has been filed. The whole nominal capital of £250,000, in £10 shares, has been taken up, of which 7,500 shares have been issued as fully paid. The full amount has been called on the remaining shares, and all calls (£175,000) have been paid.

SHEFFIELD TELEPHONE EXCHANGE AND ELECTRIC LIGHT COMPANY (LIMITED) (in Voluntary Liquidation).—The annual return of this Company, made up to August 1st, has been filed. The Company was registered on August 28, 1890, with a capital of £100,000, divided into 2,000 preference and 8,000 ordinary shares of £10 each, to take over as a going concern and carry on the business of a Company of the same name, which was incorporated September 11, 1888. At the time of making up, 4,000 ordinary, and 1,162 preference shares had been taken up, of which the ordinary shares had been issued; with £8 considered as paid on each to the shareholders of the old Company. Upon the preference shares the full amount has been called, resulting in the payment of £11,440, leaving £180 in arrears. The principal shareholder is John Tasker, of Crookes House, Sheffield, who holds 3,090 ordinary and 100 preference shares.

SHERRIN ELECTRIC POWER GENERATOR COMPANY (LIMITED).—This Company has, we understand, been struck off the list of joint-stock companies.

CITY NOTES, &c.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation to, this Company's £125,000 Four and a-Half per Cent. Perpetual Debenture Stock.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended Sept. 4th were £737, as against £672 for the corresponding period of last year, being an increase of £65. The total receipts for half-year amount to £7,690, against £7,069 in the corresponding period of 1891, being an increase of £621.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts for the month of August were £3,100, as compared with £3,111 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the month of August were £1,884, against £1,631 for the corresponding period last.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the month of August amounted to £49,069, against £53,398 in the corresponding period of 1891.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of August amounted to £42,035, and to £41,791 in the corresponding period of last year, an increase of £244.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for August, 1892, amounted to £23,600; and from January 1st to August 31st to £175,600. In the corresponding months of 1891 and 1890 the amounts were £189,400 and £181,000 respectively.

NEW ZEALAND ELECTRICAL SYNDICATE (LIMITED).—This Syndicate, whose offices are situate at 53, New Broad-street, E.C., are asking for £20,000 capital in 2,000 shares of £10 each; the authorised capital being £100,000. The Syndicate was incorporated in December, 1890, to obtain electric lighting concessions in New Zealand and elsewhere, to take over certain central stations erected by the Gülcher Electric Light and Power Company (Limited), at Wellington, New Zealand, and to take over the benefit of a contract between that Company and the local authorities of Wellington for lighting the streets of that city. By an Act passed in 1891 the Syndicate is authorised to supply the City of Wellington with electric current, and in the Act the Corporation reserve powers to purchase the undertaking at the end of 10, 14, or 21 years, upon paying to the Syndicate the capital invested, and making up its average dividends to 10 per

Digitized by Google

cent. for the period which has expired after the purchase takes place. From calculations made by the Directors it is estimated that an immediate dividend of 5 per cent. may be relied upon. In addition to the Board of Directors there is a local Board in New Zealand, the Managing Director there being Mr. A. I. Suckling-Baron, M.I.E.E. The secretary is Mr. T. C. Morgan. Amongst the English Board of Directors are Mr. D. de Castro, Mr. G. Grewing, Mr. M. S. Vanderbyl, and Mr. J. Evelyn Williams, M.I.C.E.

ROCKHAMPTON (QUEENSLAND) GAS AND COKE COMPANY (LIMITED).—The Directors' report of this Company was recently issued, and the Directors announce that since the last meeting the bulk of the electric lighting plant had arrived and was in course of erection. The Company appears to have issued debentures in anticipation of the demand for the electric light, a portion of which was devoted to the erection of a new gas-holder, and, notwithstanding this diversion, the various extensions decided upon by the Directors appear to be making a good return to the shareholders. The last dividend declared was at the rate of £10 per cent. per annum.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Sept. 2, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,106.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated receipts of this Company for the fortnight ended August 31, 1892, were £1,939, compared with £2,428 for 1891, showing an increase of £489.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 748.—Vol. XXIX. FRIDAY, SEPTEMBER 16, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6*

NOTES.

Mr. Binswanger in his letter which will be found in our Correspondence columns, while sticking to his guns, "doth protest too much;" he has a good case, and it is a pity to spoil it by exaggeration. When he says "nor has a single fire occurred which could be traced to electricity as its cause" in England, of course he is thinking of the oft-repeated claim that no fire has occurred where the Phœnix rules have been enforced. This is highly creditable to their inspector, but it is common knowledge; no one can deny the great value of his exertions, but it is possible to overestimate them. Mr. Binswanger's *précis* of our remarks in his third paragraph is a little crude, and he asks our reasons for supposing that matters in America are taking their best possible course. We see in the first place that they are, if we may venture to say so, on the right track with their porcelain fittings, &c. The quality of the glaze is a refinement which need not concern us here, especially in connection with the American climate; and the indiscriminate method of fixing screws is a matter to which only a portion of our manufacturers have yet paid attention, but which is now receiving the care which it deserves. For these and a dozen other details Mr. Binswanger says that we have to thank Mr. Musgrave Heaphy. We do not underestimate the importance of details; all work is an accumulation of details. We should rather have credited Mr. Heaphy with the principles of which these details are the expression. Americans seem to be beginning to appreciate the principles, and surely they, better than any other nation, may be expected to invent details, their really strong point.

Further than this we really think, even if we have to differ diametrically from Mr. Binswanger, that Americans, with their enormous experience, and with requirements and habits which differ so widely from ours, are able to look after themselves, and to formulate their own rules and methods of inspection. If in the course of the next ten years their new rules pass through nineteen editions as the Phœnix rules have done, we hope that they will take the eighteen opportunities of bringing them properly up to date, so that they may, until the next edition, be self-explanatory. Mr. Binswanger asks if "during the past stage of electrical manufacturing, and even at the present moment, any more definite rules could possibly be devised without being subject to almost weekly alteration." Here we must differ. The rules of the Institution of Electrical Engineers, issued in 1883, have been only once remodelled. So far from being "hard and fast," they have become practically obsolete, simply because they are not up to date. Revise by all means, but surely once in six months is often enough. And (*pace* Mr. Binswanger with his weekly issue) if so, why not let them bear a definite interpretation until the next edition?

We publish this week the first portion of an interesting historical *résumé* communicated to the Institution of Mechanical Engineers by Mr. Henry Deadman at their July meeting in Portsmouth, which pressure on our space has hitherto compelled us to hold over. In spite of many handsome tributes to the utility of electricity, so far as the Royal Navy is concerned, enthusiasts of the "all-by-electricity" type were dissatisfied because the author admitted that he was not over sanguine of the success of a more general application of electricity on board modern men-of-war. One speaker, as will be seen from the brief report of the discussion, which we shall reproduce from *Engineering*, thought that the whole question of electricity on board warships was unsatisfactory, and advocated the substitution of electricity for hydraulic power and compressed air.

For our own part we must confess to a decided preference for a slow but sure policy in this matter. A battleship in action will be no place for untried apparatus in inexperienced hands. At the same time there are several applications, such as hoisting shot, training guns, &c., for which electric motors would seem to be eminently adapted. Moreover, the advantages accruing from what we may term unity of mechanism are by no means negligible. If electricity can be shown to be the best for nine things out of ten and a good second in the tenth instance, by all means let it be generally adopted.

We note that Mr. Deadman talks of a search light as "evidently affording a good mark for an enemy's fire." We wonder if he has heard of the results of experiments both in this country and in France, results which tend to show that a projector, even when unprotected, enjoys a remarkable immunity from serious damage. The military authorities, however, when using search lights, place the projectors themselves out of harm's way, and direct the beam on to a reflector which, easily replaceable, is alone exposed. Do the exigencies of naval warfare altogether forbid this device?

Digitized by Google

The modern man-of-war carries three dynamos as a rule, and one of these is always running, since a large part of the space "below" would be in absolute darkness but for electric light. So large a use has been made of this constant supply for many other purposes, that if all the dynamos became disabled in action, the vessel might as well retire from the contest. An electromagnet could be arranged so that when this unfortunate contingency arrived the flag would be automatically hauled down. Inventors please note.

With a view no doubt of maintaining the interest of its issues at a high level during the dull season, the *Electrical World* has for some weeks past opened its columns to numerous contributions on the relative merits of simple alternating, two-phase and three-phase currents, and to a discussion of the reasons which have led to the adoption of low frequencies in Germany and high frequencies in America.

Mr. Steinmetz in a communication, some extracts from which we give in our Notes columns this week, goes a long way to prove that this particular differerence of practice is due, as is generally the case, not so much to a mere desire to act differently to others, but to dissimilar conditions. In Germany it seems that the alternate current is only preferred to the continuous, either because its adoption enables a single station to supply a somewhat larger area, or because it affords some flexibility in the choice of a site for the generating centre. The mains, whether for continuous or alternating currents, are almost invariably laid only in the denser districts of thickly populated towns. Hence the possibility of sub-stations, low pressure distributing mains and those low frequencies, to which indeed the German *penchant* for slow speed direct coupled engines gives added force. In America on the other hand the alternate currents were preceded in all the denser districts by the three-wire system, and in consequence their use has been limited to the supply of straggling suburbs or scattered towns. Hence the practice of transformers in every house, to which custom the employment of high frequencies is due.

Our contemporary, *Nature*, devoted twelve amply illustrated columns to the planet Mars in last week's issue, and dwelt at considerable length upon the suggested methods of signalling to that planet, All the navies in the world are imagined to flash their search lights simultaneously; but there would remain, it says, the question of the intensity of the light. "What do electricians say is possible in this direction?" After Sir R. Ball has shown so clearly in the *Fortnightly* and in the *Graphic* that the thing is absurd, it is hardly worth while wasting space over it. Three systems have been proposed, first, to describe one of the simpler figures of Euclid on the Sahara or in Siberia, with canals, trees, or fires; the Galton system of mirrors, fifteen yards square, used as a large heliograph; and the Haweis system of handling a main switch controlling "the lights of London" during the small hours of the night. Confining ourselves to the intensity of the light, it may be remarked that taking the reflecting power of the earth to be the same as that of the moon, or according to Zöllner about 0·1, this agrees with another observation which makes the moon about three candle-power per square inch of its surface. According to L. Weber the sun gives from 500,000 to 1,000,000 candle-power per square inch. In the Galton system, therefore, there would be ample difference between the signal and its background. The Siberia system could not give a difference of more than 150 to 1. The Haweis system is, of course, out of the question, for if London were decently lighted all over, it would be an irresolvably nebulous spot, even if seen from the moon. A big search light might give 40,000 candles per square inch, and 10,000,000 candle-power could be provided without much difficulty within the space of a few square feet; at 3 candle-power per square inch the satellite of Mars gives just about a billion candle-power; astronomers may judge as to which of these two luminous objects would be the more easily visible. We will gladly enter into further calculations as soon as the inhabitants of Mars show some sign of commencing a correspondence, which, in the month of September, would be excusable.

The Hunnings Transmitter Patent.—This Patent, No. 3,647 of 1878, expires to-day.

Poplar District Board of Works.—At a recent meeting this Authority decided to apply for an Electric Lighting Order.

The Tesla Motor.—It is reported that the German patent for this motor has been acquired by the Helios Company of Ehrenfeld.

Personal.—We learn that Mr. Louis Brockman has resigned the position of Supply Superintendent to Messrs. Woodhouse and Rawson, having been appointed Manager of the Epstein Accumulator Company.

Honours.—Mr. James Sivewright, joint author with Mr. Preece of a well-known manual on Telegraphy, and at present Commissioner of Crown Lands and Public Works of Cape Colony, has been created a K.C.M.G.

Winter Sessions.—Particulars with regard to the 1892-93 Session and Evening Classes at King's College (London) and the Glasgow and West of Scotland Technical College will be found in our advertisement columns.

Oxford.—The General Purposes Committee of the Town Council have reported in favour of an additional expenditure of not exceeding £210 per annum, on a three years' contract, for lighting the central portions of the city with arc lamps.

The Western Union and Postal Telegraph Companies.—The *Western Electrician* states that there have been rumours about a proposed consolidation of the Western Union and Postal Telegraph Companies, but that little reliable information is obtainable.

Bradford.—At the last meeting of the Town Council, Alderman F. Priestman, moving the adoption of the minutes of the Gas and Electricity Supply Committee, stated that during the past half year there had been a profit on the electricity department of £387. 7s. 2d.

The City Arc Light Lanterns.—At a recent meeting of the Commissioners of Sewers it was stated in answer to several inquiries that the "frosted" glass used in the arc light lanterns was the result of a long series of experiments by Colonel Haywood, and it had been definitely decided upon.

University College, Liverpool.—Amongst the various courses of instruction to be carried on during the forthcoming Session at University College, Liverpool, we note in the recently issued prospectus, that Dr. Oliver Lodge will conduct courses on Electro-Technology and Electrical Engineering.

Digitized by Google

Leeds.—The electric light mains are now being laid in the thoroughfares which it is proposed to light as a commencement. The erection of the central station is also progressing rapidly. There seems to be no reason to doubt that the Company will be in a position to supply electricity in November.

Fire Insurance Rules in America.—In describing a machine for painting wooden mouldings, the *Electrical Engineer* of New York says that in most of the large cities of America the boards of fire underwriters require all mouldings through which electric wires run to be coated inside and out with insulating compound.

Reading.—At a recent meeting of the Reading Town Council, it was decided not to apply for a Provisional Order, but to give consent to the grant to the Reading Electric Supply Company of a Provisional Order, if arrangements could be made for the insertion in the Order of provisions satisfactory to the council. These provisions included limitations as to price and dividends, and the right to purchase at any time.

Electric Car Accident.—A Reuter's telegram dated St. Louis, September 13th, reports a fatal accident in one of the streets of that city. As a motor car, with passenger car attached, was going down a steep gradient, the man in charge lost control over the motor and the cars rushed down the incline. Turning a curve the rear car ran off the rails and upset. One passenger was killed on the spot, while 17 others were injured.

An Electric Shunting Engine.—Messrs. Mather and Platt, of Salford, have recently constructed a heavy electric locomotive for use at some large iron works in Sweden. This locomotive is designed to work with an electromotive force of about 300 volts, and in external appearance is similar to those on the City and South London Railway. The motor is of the double armature type, the motors being connected to the axles through 10 to 1 spur gearing. An overhead wire, 16ft. from the rails, furnishes the current, the collectors consisting of an iron bar at each end of the locomotive, carried on upright pipe pillars.

Cambridge.—It is reported by the local press that the workmen engaged by the Cambridge Electric Supply Company to lay their mains buried the pipes without running pilot wires, with the result that some portions had to be dug up again. The central station has been considerably delayed by the fact that it was found necessary to go 12ft. deeper than was anticipated in order to find a suitable foundation for the chimney shaft. It is therefore probable that the current will not be available till towards the end of October. Up to the present time applications have been received by the Company for the provision of about 5,000 incandescent lights, and it is expected that a fair number of arc lamps will also be supplied.

Charterhouse Science and Art Schools and Literary Institute.—The winter session of this, one of the largest science and art schools in the United Kingdom, will commence on Saturday, September 24th, under the presidency of the Rev. Henry Swann, M.A. During the late session upwards of 1,060 students, mostly elementary teachers, availed themselves of the privileges afforded by this institution, and of this number nearly 700 presented themselves for examination, and were successful in obtaining a large number of class certificates and also a fair number of honours certificates awarded by the Science and Art Department of South Kensington. Instruction of a practical character is given in most of the sciences at a very nominal fee.

The National Telephone Company and their Wires.—At a recent meeting of the Carlisle Town Council the Town Clerk stated that in August, 1885, an agreement was entered into between the Corporation and the Telephone Company for the erection of telephone wires. The agreement was for seven years, and the period had now expired. The Surveyor said that he had written half a dozen letters to the Company asking for some plans showing the wires they had in the city, and the dates when they were put up, but he could not get any information. The Town Clerk said the Company were supposed to furnish particulars every year. It was agreed that the Town Clerk should write to the Company, informing them that if they did not carry out their agreement proceedings would be taken against them.

Thunderstorms in Spain.—According to a Reuter's telegram, dated Madrid, September 8th, during the past few weeks several thunderstorms have passed over Spain, producing as disastrous effects as the storms which swept the country at the end of spring and the beginning of summer. At Aguilar, in Cordova, the thunder is described as having been deafening, and the lightning fused about 50 metres of wire, forming part of the local electric light installation. The inhabitants, believing the intensity of the storm was increased by the electric plant, cut down some of the "mains" belonging to the Electric Light Company. In Granada much damage was caused to the crops, especially at Nerja and Torres, where the telegraph poles were blown down. A gentleman was killed by lightning near the station of Campanillas. At Ecija the tower of the Church of Santa Barbara was struck by lightning, and the building has since been closed as being dangerous. At Fuentalama a woman and her daughter were killed by lightning, and a boy was injured.

The Electrical Deposition of Soot.—During the recent meeting of the British Association in Edinburgh, the Chemical Section paid a visit to the oil and printing ink works of Messrs. A. B. Fleming and Co. A large shed in the works is devoted to the manufacture of printer's black. This is accomplished by allowing a thick heavy oil to flow through a pipe and drip slowly into a large closed chamber. The oil here burns slowly, producing a dense volume of intensely black soot, which is removed from time to time, and is used exclusively for the black printing inks. The deposition of the dense black smoke in these close chambers is very slow. The smoke particles, however, gradually coalesce and fall to the bottom of the chamber as black soot, but even when the depositing chambers are large the yield of printer's black is small. Mr. Robert Irvine, the chemical director of the firm, has, says *Industries*, devoted some time towards devising a means for hastening this deposition, and has found that, by adopting Dr. Lodge's suggestion of a series of electrified metal points placed within the chamber, the formation of the deposit is much accelerated. The process has not, however, so far been adopted on a large scale, owing to considerations of cost.

Electric Lighting in Chelsea.—The following extract from the report of the surveyor of the Chelsea Vestry for the year 1891-92 will be of interest:—"At the end of July the Vestry appointed me an inspector under the Electric Lighting Acts, so as to empower me to examine the records of pressure, &c., kept by the Electric Lighting Companies. The Cadogan Electric Lighting Company not yet having complied with their Act as regards a money deposit, the Board of Trade have not served them with the usual regulations as to safety and supply, so that the only Company keeping records which the Vestry's inspector can examine is the Chelsea Electricity Supply Company. From time to time I have inspected the records kept by this Company, and find that the pressure recorded by their instruments is always above 100 volts—it usually being about an average of 103 volts—except on one or two occasions when alterations were being made to the engines. I consider that their system shows very satisfactory results, and I am of opinion that they keep well within the limits laid down in the Board of Trade's regulations.

Houses Lighted by Electricity.

The number of houses lighted by electricity in Chelsea was:—

	1889-90.	1890-91.	1891-92.
Chelsea Electricity Supply Company ...	113	215	312
Cadogan Electric Light Company.....	25	16	18
London Electric Supply Corporation ..	1	2	2
	139	233	332

Mechanically Exhausted Incandescent Lamps.—There appears, says *Industries*, to be a small revolution going on in American lamp manufacture, and the mechanical pump threatens to displace those of the Sprengel and Geissler type. It seems strange that it should only be found out now that mechanical pumps can give sufficiently good vacua; and it is also curious that these pumps should give the vacua claimed for them. Most of the mechanical pumps described comprise little in advance of the various kinds that have been in use in this country and on the Continent for other purposes requiring good vacua—such as making ice by the evaporation of water—but

Digitized by Google

until recently no one thought of using such pumps for the final exhaustion of incandescent lamps. On the one hand a great deal of nonsense has been talked about the extreme perfection of the vacuum produced by mercury pumps, and the durability of lamps made with such vacua; but, on the other hand, some of the statements of the advocates of mechanical pumps are difficult to admit. For instance, a favourite claim is that a residual vacuum of hydrocarbon is good, because it is absorbed by the hot carbon, so that the vapours from the oil used to lubricate the pump do not destroy the vacuum. It is needless to remark that hot carbon decomposes hydrocarbon vapour, and leaves a greater volume of hydrogen. Though this may be the case, it may also be true that a mechanical pump can produce a sufficiently good vacuum. If this be so, it will be a matter of great convenience, for though there is not much room for reduction of expense in the exhaustion of lamps, every farthing will be important as soon as competition becomes keen.

Electric Traction in Montreal.—A short time ago the Montreal City Council, says the *Electrical Engineer* of New York, invited tenders for the privilege of operating street railways by electricity in that city, in response to which tenders were received from several syndicates representing American and Canadian capitalists. After many meetings of the council and much virulent discussion of the merits of the different tenders, the contract was awarded to the Montreal Street Railway Company on July 19th. This Company, who at present operate the horse-railway system in the city, will now have the exclusive right to propel cars by electricity on the principal thoroughfares for the next 30 years. New lines and old lines are all to be laid with English grooved rails. As for nearly four months of the year the Montreal streets are covered with snow, often to a depth of two or three feet, the operation of the cars in winter has received careful consideration. In order to enable the electric cars to run all winter, the snow will be removed from the entire roadway of the streets on their routes, leaving a layer of sufficient depth on either side of the track for sleighing, and the tracks will then be kept clear by the use of sweepers and ploughs. The city and Company are to share the expense of removing the snow. At present the horse cars run for about eight months of the year, and during the remaining time sleighs or stages are used, the stages being used when the streets are not in good condition for sleighing. The prospect of having electric cars that will run all winter and give a rapid and reliable service in spite of the snow is said to give great satisfaction to the inhabitants of Montreal. Material, including 80 cars, has already been ordered. The cars are to be equipped with two 25 H.P. single reduction motors each, in order to have ample power for ascending grades. These motors have been ordered of the Royal Electric Company. For the present, this company (the Royal) will furnish the power for running the cars from their lighting station, and are building eight 250 H.P. generators for this purpose. The poles of the Bell Telephone Company and those of the Royal Electric Company are being used for the suspension of the trolley wire as far as possible.

The Frequency of Alternate and Polyphase Current Systems.—The reasons why on the Continent a comparatively low frequency of 40 to 50 periods per second has been adopted, and here exclusively frequencies of 120 to 150 periods are used, are, writes Mr. Chas. Steinmetz in the *Electrical World*, entirely out of the choice of the motor designer, because based upon the differences in the very conditions of social life here and there. On the Continent, continues Mr. Steinmetz, when a city intends to introduce the electric light—first certainly only for the denser populated and better situated parts—a committee of city officials and business men is elected; this committee again elects a committee of experts—university professors—and after meeting for a couple of years and filling the vacancies caused by the death of members, the committees get so far as to ask for bids from the electric supply companies. After careful study of all the propositions, for continuous, alternating, &c., current systems, naturally the committee know still less than before which system is the best, and consequently some more committees are elected, &c. Now, the consequence of this method is, that alternate and continuous current systems are co-ordinate and competitors, both supplying only denser populated districts, and where the alternating system is chosen it is used only because it allows the supply of a larger area from one central station, and the location of the central station in the suburbs. But the consumers living near together, a secondary network can reach them, and consequently the transformer is used as secondary or sub-station, feeding into a secondary network which supplies many consumers. Large units of transformers are used then, and they are cut out or cut in according to the fluctuations of load. Because of the larger size of transformers, they can be worked very economically with low frequency, and consequently low frequency is used on the Continent, the more as direct coupled slow-speed engines are preferred. In the United States the alternating current, entering the field, found the denser populated city districts occupied already by continuous-current systems, which distributed light and power, and in this latter respect were superior to the alternating systems of those days. But in the suburbs, in smaller cities and scattered districts, the alternating current found a field where the continous-current was entirely out of competition. In consequence of this the European system of transformer sub station and secondary distributing mains is not applicable, and the individual consumers can be reached only by the primary mains, and have to be provided with separate transformers of smaller size. In this way the high frequency employed throughout in this country is necessitated by the direct primary distribution to the customers.

Fireproof Insulation.—Fires from electric wires laid in metal conduits are, says Mr. Reginald A. Fessenden in the *Electrical World*, an impossibility, and fires from switch and fuse boards are simply a question of proper design. There is, however, always a danger from the use of flexible cords or pendent lamps, especially when hung near curtains or tapestry. The only safety in this case is in the use of a fire and water proof, flexible insulation. The following recipe, which it was actually proposed by Mr. Edison to use commercially, is then given by Mr. Fessenden:—100 parts of linseed oil, 50 parts strained Mexican asphalte, and 10 parts zinc chloride are boiled down at 300°C., till all the zinc chloride has combined with the other materials. The mixture is then put in a sort of ice-cream freezer, and stirred up while 50 parts of antimony pentachloride are run in, the mixture being kept cool by a water jacket. After stirring for an hour, boiling water is run in, and the mixture heated by passing steam into the water jacket. After mixing for another hour all the free acid will be found to be washed out, and the material is then ready to be applied to the wire. This gives a dark product, however, and is, moreover, more expensive than the product obtained by simply passing chlorine into a hydrocarbon, such as paraffin, and then washing. In this case we get a substance very much like paraffin, but heavier, more easily acted on by alkalies, uninflammable, which may be held in a Bunsen flame till it is reduced to charcoal, without showing more signs of ignition than a piece of marble. Several hundred feet of wire coated only with these substances were coiled up in tubes of salt water. After the lapse of several months the insulation was still high, while samples three years old show no signs of deterioration. The practical method of obtaining these substances is very simple. The asphalte or paraffin is heated till it melts, and chlorine gas is passed into it. Of every two atoms of chlorine that goes in, one unites itself with an atom of hydrogen and passes off, the other takes the place of the hydrogen atom. This goes on till enough of the hydrogen has been replaced by chlorine to render the substance non-inflammable. The substance is then taken out, and, still kept in the melted state, is washed with boiling water in a machine like an ice-cream freezer, till all the acid remaining has been thoroughly washed away. It is then allowed to cool, and is masticated to remove the remaining water, when it is ready for use. It may be mentioned, adds Mr. Fessenden, that the gases given off from these materials when heated to such a temperature as to cause decomposition will not support combustion. For instance, if wood shavings are partly covered with the composition, and placed in a box and lit, so soon as the greyish decomposition vapours begin to come off freely the fire is put out.

ELECTROMAGNETIC THEORY.—XXXVI.

BY OLIVER HEAVISIDE.

(*Continued from page 479.*)

§ 163. We see from the preceding that when it is the electric force that is given in a dielectric there is no difficulty in finding the displacement; and conversely, when the displacement is given, the electric force similarly becomes known through the values of the principal permittivities. Suppose, however, that the data do not include a knowledge of either the electric force or the displacement, both of which have to be found to suit other data. It is then sufficient to find either, the linear connection settling the other. Thus to take an explicit case which has, for a reason which will appear, a special interest, suppose the dielectric medium to have uniform permittivity transverse to the axis of **k**, but to be differently permittive to displacement parallel to this axis. Further, put a point-charge q at the origin, and enquire what is the equilibrium distribution of displacement.

The statement that there is a charge q at the origin means nothing more than that displacement diverges or emanates from that place, to the integral amount q. We also understand, of course, that the displacement has no divergence anywhere else. But the manner of emanation is, so far, left quite arbitrary. Certain general results may, however, be readily arrived at. To begin with, if the medium is isotropic, the emanation of the displacement must not favour one direction more than another, from which it follows that the displacement at distance r from the source is spread uniformly over the area $4\pi r^2$, so that $q/4\pi r^2$ expresses its density. Now if we alter the permittivity to displacement parallel to **k** only, we favour displacement in that direction if the permittivity is increased, at the expense of the transverse displacement, because the total amount, which measures the strength of the source, is the same. Conversely, if we reduce the permittivity parallel to **k**, we favour the transverse displacement. The lines of displacement, originally spread equably, therefore separate themselves about the **k** axis (both ways), and concentrate themselves transversely, or about the equatorial plane, the plane passing through the charge which is cut by the **k** axis perpendicularly.

If we carry this process so far as to reduce the permittivity along **k** to zero, there can be no displacement at all parallel to **k**, so that the displacement must be entirely confined to the equatorial plane itself. In this plane it spreads equably from the source, because of the transverse isotropy assumed at the beginning. The amount q therefore spreads uniformly over the circle of circumference $2\pi r$ in the displacement sheet, so that the density (linear) is now $q/2\pi r$. The law of the inverse square of the distance has been replaced by the law of the inverse distance, with confinement to a single plane, however.

Next, if we introduce planar eolotropy, say by reducing the permittivity in direction **j**, we cause the displacement in the sheet to concentrate itself about the **i** axis, at the expense of the displacement parallel to **j**. Finally, if we abolish altogether the permittivity parallel to **j**, the whole of the displacement will be confined to the **i** axis, half going one way and half the other.

We may go further by introducing heterogeneity. Thus, reduce the permittivity on one side of the equatorial plane. The effect will be to favour displacement on the other side; and, in the limit, when the permittivity is altogether abolished on the first side, the whole of the displacement goes unilaterally along the **k** axis on the other side.

In the case of the planar distribution of displacement, the surface-density is infinite, but the linear-density is finite, except at the source. We may, however, spread out the source along a finite straight line (part of the **k** axis) when the displacement will simultaneously spread out in parallel sheets, giving a finite surface-density. Similarly, in the case of the linear distribution of displacement along the **i** axis, we may spread out the source upon a portion of the **j**, **k** plane, when the former line of displacement will become a tube, with finite surface-density of displacement inside it.

In the above manner, therefore, we obtain a general knowledge of results without mathematics. Except, however, in the extreme cases of spherical isotropy, of planar isotropy with zero permittivity perpendicular to the plane, and of purely linear displacement due to the vanishing of the transverse permittivity, and other extreme cases that may be named, we do not obtain an exact knowledge of the results, except in one respect, that the total displacement must always be the same. Return, therefore, to the case of initial isotropy upset by changed permittivity parallel to the **k** axis, or, if need be, with three different principal permittivities, so that the displacement is

$$\mathbf{D} = \mathbf{i}.c_1\mathrm{F}_1 + \mathbf{j}.c_2\mathrm{F}_2 + \mathbf{k}.c_3\mathrm{F}_3 = c\mathbf{F}, \quad . \quad . \quad . \quad (32)$$

if **F** be the electric force. We know that in the state of equilibrium, there must be no voltage in any circuit, or the curl of **F** must be zero, so that **F** must be the slope $-\nabla\mathrm{P}$ of a scalar P, the potential. Furthermore, the divergence of **D** is the electrification-density ρ. Uniting, then, these results, we obtain

$$\mathrm{div}(-c\nabla\mathrm{P}) = \rho, \quad . \quad . \quad . \quad . \quad . \quad . \quad (33)$$

or

$$(c_1\nabla_1^2 + c_2\nabla_2^2 + c_3\nabla_3^2)\mathrm{P} = -\rho, \quad . \quad . \quad . \quad (34)$$

which is the characteristic of P when referred to the principal axes. Now when there is a point-source at the origin, and the three c's are equal, we know that the potential is $q/4\pi rc$ at distance r. From this, remembering that r^2 is the sum of the squares of the components of **r**, it is easy to see that the potential in the case of eolotropy is

$$\mathrm{P} = \frac{fq/4\pi}{(x^2/c_1 + y^2/c_2 + z^2/c_3)^{\frac{1}{2}}} = \frac{fq/4\pi}{(\mathbf{r}c^{-1}\mathbf{r})^{\frac{1}{2}}}, \quad . \quad . \quad (35)$$

where f is some constant, because this expression (35) satisfies (34) with $\rho = 0$, that is to say, away from the source.

The constant f may be evaluated by calculating the displacement passing through the surface of any sphere $r =$ constant, according to (35), and equating it to q. The result is $f = (c_1c_2c_3)^{-\frac{1}{2}}$. The complete potential in the eolotropic medium due to the point-source q at the origin is therefore

$$\mathrm{P} = \frac{q/4\pi}{(c_1c_2c_3)^{\frac{1}{2}}(\mathbf{r}c^{-1}\mathbf{r})^{\frac{1}{2}}}. \quad . \quad . \quad . \quad . \quad . \quad (36)$$

The equipotential surfaces are therefore ellipsoids centred at the charge, the equation of any one being

$$\mathbf{r}c^{-1}\mathbf{r} = \frac{x^2}{c_1} + \frac{y^2}{c_2} + \frac{z^2}{c_3} = \text{constant}, \quad . \quad . \quad . \quad (37)$$

so that the lengths of the principal axes are proportional to the square roots of the principal permittivities. The lines of electric force cut through the equipotential surfaces at right angles. But the lines of displacement do not do so, on account of the eolotropy. To find their nature, first derive the electric force from the potential by differentiation. Then (36) gives

$$\mathbf{F} = \frac{(q/4\pi)c^{-1}\mathbf{r}}{(c_1c_2c_3)^{\frac{1}{2}}(\mathbf{r}c^{-1}\mathbf{r})^{\frac{3}{2}}}, \quad . \quad . \quad . \quad . \quad (38)$$

and the displacement is obtained by operating by c on this, which cancels the c^{-1}, and gives

$$\mathbf{D} = \frac{(q/4\pi)\mathbf{r}}{(c_1c_2c_3)^{\frac{1}{2}}(\mathbf{r}c^{-1}\mathbf{r})^{\frac{3}{2}}}. \quad . \quad . \quad . \quad . \quad (39)$$

The displacement is therefore radial, or parallel to **r** itself. That is, the lines of displacement remain straight, only altering their distribution as the medium is made eolotropic.

Observe, in passing, that the scalar product **FD** varies as P^4; that is, the density of the energy varies as the fourth power of the potential. Also note that **Fr** is proportional to P; that is, the radial component of **F**, or the component parallel to the displacement, varies as P/r.

If we select any pair of equipotential surfaces between which the electric force and displacement are given by (38), (39), we may, if we please, do away with the rest of the electric field. That is, we may let the displacement and electric force terminate abruptly upon the two ellipsoidal surfaces. What is left will still be in equilibrium. For the voltage remains zero in every circuit possible. This is obviously true between the surfaces, because no change has been made there. It is also true in any circuit beyond the surfaces, because of the absence of electric force. And lastly, it is true for any circuit partly within and partly beyond the region of electric force, because the electric force is perpendicular to the surface. So the electric

Digitized by Google

field is self-contained. The electrification is on the surfaces, where the normal component of the displacement measures the surface-density. That is, there is a total electrification q on the inner and $-q$ on the outer surface. The elastance of the condenser, or "leyden," to use Lord Rayleigh's word, formed by the two surfaces, is the ratio of the voltage between them to q. That is, the coefficient of q in (36) is the elastance between any equipotential surface and the one at infinity.

In thus abolishing the electric field beyond the limited region selected, we may at the same time change the nature of the medium, making it isotropic, for example, or conducting, &c. Any change is permissible that does not introduce sources that will disturb the equilibrium of the electric field between the equipotential surfaces.

Starting from isotropy, when the equipotential surface is a sphere, if we keep $c_1 = c_2$ constant, and reduce c_3, the sphere will become an oblate spheroid, like the earth (and other bodies)—flattened at the poles. Let the common value of c_1 and c_2 be denoted by c_0, then the potential due to the central charge q is

$$\mathrm{P} = \frac{q/4\pi}{c_0 c_3^{\frac{1}{2}}(x^2/c_0 + y^2/c_0 + z^2/c_3)^{\frac{1}{2}}}, \quad . \quad . \quad . \quad (40)$$

and the displacement and electric force are given by

$$c\mathbf{F} = \mathbf{D} = \frac{(q/4\pi)\mathbf{r}}{c_0 c_3^{\frac{1}{2}}(x^2/c_0 + y^2/c_0 + z^2/c_3)^{\frac{3}{2}}}. \quad . \quad . \quad (41)$$

As c_3 is continuously reduced the oblate spheroid of equilibrium becomes flattened more and more, and is finally, when $c_3 = 0$, reduced to a circular disc. The displacement is now entirely in the equatorial plane, so that if we terminate the displacement at distance r from the centre, we obtain a circular line of electrification (that is, on the edge of the disc). We may have the displacement going from the central charge to an equal negative charge spread over the circle, or from one circle to another in the same plane; and so on.

Similarly, when c_1 and c_2 are unequal, but $c_3 = 0$, the circular disc is replaced by an elliptical disc. But, without introducing transverse eolotropy, we see that the abolition of the permittivity in a certain direction has the effect of converting the usual tridimensional solutions relating to an isotropic medium to bidimensional solutions, in which the displacement due to sources situated in any plane perpendicular to the axis of symmetry is also in that plane. We may have any number of such planar distributions side by side, with the axis of symmetry running through them. But they are quite independent of one another. If we restore the permittivity parallel to the axis of symmetry, the displacement will usually spread out to suit tridimensional isotropy. The exception is when every plane perpendicular to the axis has identically similar sources, similarly situated. Then the restoration of the permittivity will produce no change.

§ 164. Let us now pass to what is, at first sight, an entirely different problem, but which involves essentially the same mathematics. As before, let there be a point-source of displacement at the origin, but let the dielectric medium be homogeneous and fully isotropic. The displacement will be radially distributed, without bias one way or another. Now, keeping the charge fixed in space, imagine the medium to move steadily from right to left past the charge. How will this affect the displacement?

If we desire the solution expressing how the displacement changes from its initial distribution, as the medium is brought from rest into steady motion, we can obtain it by going the right way to work. But it is complex, and will, therefore, not be given here, especially as it is not intelligible without close study. But if we only wish to know the finally-assumed distribution of displacement when the initial irregularities have subsided, we may obtain and express the result in a comparatively simple manner. Thus, to begin from the foundation, we have the two fundamental circuital laws,

$$\mathrm{curl}\,(\mathbf{H} - \mathbf{h}) = cp\mathbf{E} + \rho\mathbf{u}, \quad . \quad . \quad . \quad . \quad (42)$$

$$\mathrm{curl}\,(\mathbf{e} - \mathbf{E}) = \mu p\mathbf{H}, \quad . \quad . \quad . \quad . \quad . \quad (43)$$

where $\mathbf{E}$ and $\mathbf{H}$ are the electric and magnetic forces, μ and c the inductivity and permittivity, ρ the density of electrification, supposed to have velocity $\mathbf{u}$; and $\mathbf{e}$, $\mathbf{h}$ are the motional electric and magnetic forces given by

$$\mathbf{e} = \mathrm{V}\mathbf{w}\mathbf{B}, \qquad \mathbf{h} = \mathrm{V}\mathbf{D}\mathbf{w}, \quad . \quad . \quad . \quad (44)$$

$\mathbf{B}$ and $\mathbf{D}$ being the induction and displacement, and $\mathbf{w}$ the velocity of the medium. (See equations (1), (2), or (3), (4), § 66, and equations (5), (6), § 44, for the motional forces. Also §§ 33 to 70 generally.)

Now in our present case, $\mathbf{E}$ and $\mathbf{H}$ are steady, and the electrification is at rest. The right sides of (42), (43) are therefore zero, which is a great simplification. By (42) and the second of (44) we obtain

$$\mathrm{curl}\,\mathbf{H} = \mathrm{curl}\,\mathbf{h} = \mathrm{curl}\,\mathrm{V}\mathbf{D}\mathbf{w}. \quad . \quad . \quad . \quad (45)$$

But $\mathbf{B}$ is circuital, and therefore so is $\mathbf{H}$. It follows that

$$\mathbf{H} = \mathrm{V}\mathbf{u}\mathbf{D}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (46)$$

if we substitute $-\mathbf{u}$ for $\mathbf{w}$, for future convenience. This gives $\mathbf{H}$ explicitly in terms of the displacement, when that is known, so we have no further trouble with the magnetic force.

To find the displacement, (43) gives, along with the first of (44),

$$\mathrm{curl}\,(\mathbf{E} + \mathrm{V}\mathbf{u}\mathbf{B}) = 0, \quad . \quad . \quad . \quad . \quad (47)$$

or say, $\mathrm{curl}\,\mathbf{f} = 0$, if $\mathbf{f} = \mathbf{E} + \mathrm{V}\mathbf{u}\mathbf{B}$. . . . (48)

Now put the value of $\mathbf{B}$ in $\mathbf{f}$ by (46), thus,

$$\mathbf{f} = \mathbf{E} + \mu c\mathrm{V}\mathbf{u}\mathrm{V}\mathbf{u}\mathbf{E} = \mathbf{E} + \frac{u^2}{v^2}\mathrm{V}\mathbf{k}\mathrm{V}\mathbf{k}\mathbf{E}, \quad . \quad . \quad (49)$$

since $\mu c v^2 = 1$, v being the speed of propagation of disturbances, and u the tensor of $\mathbf{u}$, supposed to be parallel to $\mathbf{k}$.

Expanding by the fundamental formula (52), § 114, we obtain

$$\mathbf{f} = \mathbf{E} + \frac{u^2}{v^2}(\mathbf{k}.\mathrm{E}_3 - \mathbf{E})$$

$$= (1 - \frac{u^2}{v^2})\mathbf{i}\mathrm{E}_1 + (1 - \frac{u^2}{v^2})\mathbf{j}\mathrm{E}_2 + \mathbf{k}\mathrm{E}_3. \quad . \quad . \quad (50)$$

Now let $\mathbf{f} = (1 - u^2/v^2)\mathbf{F}$. Insert in (50), and divide by $(1 - u^2/v^2)$. The result is

$$\mathbf{F} = \mathbf{i}\mathrm{E}_1 + \mathbf{j}\mathrm{E}_2 + \frac{\mathbf{k}\mathrm{E}_3}{1 - u^2/v^2}. \quad . \quad . \quad . \quad . \quad (51)$$

This vector $\mathbf{F}$ must also have no curl. Therefore, if P is the potential whose slope is $\mathbf{F}$, we have

$$\mathrm{E}_1 = -\frac{d\mathrm{P}}{dx}, \quad \mathrm{E}_2 = -\frac{d\mathrm{P}}{dy}, \quad \mathrm{E}_3 = -(1 - \frac{u^2}{v^2})\frac{d\mathrm{P}}{dz}, \quad (52)$$

and the components of displacement are given by

$$\mathrm{D}_1 = -c_1\frac{d\mathrm{P}}{dx}, \quad \mathrm{D}_2 = -c_2\frac{d\mathrm{P}}{dy}, \quad \mathrm{D}_3 = -c_3\frac{d\mathrm{P}}{dz}, \quad . \quad (53)$$

if $c_1 = c_2 = c$, and $c_3 = c(1 - u^2/v^2)$, . . (54)

Now observe that (53) express the displacement in terms of the electric force in an eolotropic medium at rest, whose principal permittivities are given by (54), when P represents the electrostatic potential. Our present problem of a moving isotropic medium is therefore reduced to one relating to a stationary eolotropic medium. Thus, to state the comparison fairly, when the isotropic medium moves bodily past a stationary charge, the displacement distribution becomes identically the same as if the medium were at rest, but had its permittivity in the direction of motion reduced from c to $c(1 - u^2/v^2)$. The solution is therefore given by (40), (41) in § 163, by taking $c_0 = c$, and c_3 as in (54). The displacement concentrates itself about the equatorial plane, or plane through the charge perpendicular to the axis of motion in the one problem, or axis of reduced permittivity in the other. In the limit, when the speed of motion reaches v, the speed of light, the displacement is wholly planar, as in the eolotropic case when the permittivity c_3 vanishes.

Observe, in (52), that the square of u occurs. It does not matter, therefore, which way the motion takes place, so far as the displacement is concerned. But it makes a great difference in the magnetic force which accompanies the lateral concentration of the displacement. Being given by (46), we see that $\mathbf{H}$ reverses itself when the direction of motion is reversed.

It should be carefully noted that P, which is the electrostatic potential in the eolotropic stationary medium, is not the electrostatic potential in the moving medium, although it is the same

Digitized by Google

function precisely. In the eolotropic medium its slope is the electric force **F**. In the moving medium its slope is the same force **F**, but this is no longer the electric force, which is **E** instead, obtained from **F** by (51) or (52). Again, whilst the displacement and electric force are not parallel in the stationary eolotropic medium; on the other hand, in the moving medium they are parallel, because the medium is isotropic. To complete the differences, there is no magnetic force in the eolotropic case, but there is in the moving medium, and it is its existence which allows the parallel to exist as regards the identical distributions of displacement.

Instead of moving the medium past a fixed charge, we may fix the medium, and move the charge through it the reverse way at the same speed. This is why we put $\mathbf{w} = -\mathbf{u}$. The above results apply when the charge q moves with velocity $\mathbf{u}$ through the stationary medium. But it is necessary now to travel with the charge in order to see the same results, because the origin is taken at the charge, and it is now in motion. The preliminary mathematics is therefore less easy.

The above theory of convection currents and the eolotropic comparison I have given before. I have now to add a somewhat important correction. For the opportunity of making this correction I am indebted to Mr. G. F. C. Searle, of Cambridge, who has been at the trouble of working his way through my former calculations. Whilst fully confirming my results for a point-charge, and therefore all results obtained therefrom by integration, he has recently (in a private communication) cast doubt upon the validity of the extension of the solution to the case of a moving charged conducting sphere, and has asked the plain question (in effect):—What justification is there for taking distributions of displacement calculated in the above manner, and cutting them short by surfaces to which the displacement is perpendicular, which surfaces are then made equilibrium surfaces? For example, in the solution for a point-charge, I assumed that the solution was the same for a charged sphere, because the lines of electric force met it perpendicularly. On examination, however, I find that there is no justification for this process. The electric force should not be normal to a surface of equilibrium, exceptions excepted.

The true boundary condition for equilibrium, however, needs no fresh investigation, being implicitly contained in the above. In the stationary case of eolotropy, the vector **F** must have no curl, and since it is the electric force, it is the same as saying that there must be no voltage in any circuit, so that **F** must be normal to an equilibrium surface. Now, in the problem of a moving medium with charge fixed the same condition formally obtains, viz., that **F** shall have no curl. But as it is not the electric force **E**, it is clear that the displacement (which is parallel to **E**) cannot be perpendicular to an equilibrium surface. The voltage calculated by the fictitious electric force **F** must come to zero in every circuit. The boundary condition is, therefore, that **F** is perpendicular to an equilibrium surface. That is, $P = \text{constant}$ is the equation to a surface of equilibrium (no longer equipotential in the electrostatic sense), where P is, however, the same function as in the eolotropic stationary problem of electrostatics.

Therefore, by § 163, we see that the sphere of equilibrium when the medium (isotropic) is stationary, becomes an oblate spheroid when the medium is set into a state of steady motion, the shorter axis being parallel to the line of motion. In the limit, when the speed is v, the spheroid is flattened to a circular disc, on whose edge only is the electrification.

This applies when the whole dielectric medium is moving past a fixed spheroidal surface of electrification. It equally applies when the electrification moves the other way through a fixed medium. There will be no electric force in its interior. We may therefore fill it up with conducting matter, provided we do not interfere with the free motion of the external medium through it in the one case, or with the rest of the external medium when the conductor moves through it. But in the limiting case of motion at the speed of light, when only a single circular line of electrification is concerned, it would seem to be immaterial whether the conductor be a flat disc or a sphere, subject to the reservation of the last sentence.

Whether it is possible to move matter through the ether without disturbing it forms an entirely different question, to which no definite answer can be given at present. We can, in any case, fall back upon the more abstract theory of electrification moving through the ether, without having conductors to interfere.

(*To be continued.*)

ON THE MEASUREMENT OF THE MAGNETIC PROPERTIES OF IRON.*

BY THOMAS GRAY, B.SC., F.R.S.E.

This Paper gives the method of experiment and results obtained in some investigations on the time-rate of rise of current in a circuit having large electro-magnetic inertia. The experiments were made on a circuit containing the coils of a large electro-magnet having laminated cores and pole pieces. The mean length of the iron circuit was about 250cm. and its cross section 320sq. cm. The magnetising coil had 3,840 turns, when all joined in series, and a resistance of 10·4 ohms. The coils were so arranged that they could be joined in a variety of ways so as to vary the resistance, inductive coefficient, &c., and also to allow the magnet to be used either as an open or a closed circuit transformer. The E.M.F. used in the experiments was obtained from a storage battery, and the method of experiment was to trace the curve, giving the relation of current to time, on a chronograph sheet.

One set of experiments shows the effect of varying the impressed E.M.F. on the time required for the current to attain any given percentage of its maximum strength. The results show that for any particular percentage there is always a particular E.M.F. which takes maximum time. Thus for the circuit under consideration, and with successive repetitions of the current in the same direction, it takes longer time for the current produced by an impressed E.M.F. of 4 volts to reach 95 per cent. of its maximum than it takes for the current produced by either 3 or 5 volts to reach 95 per cent. of their maximum. The results show also that, within considerable limits, the time required for the current to become uniform is on the whole nearly inversely proportional to the impressed E.M.F., and that for moderate values of the E.M.F. the time may be very great; when the E.M.F. was 2 volts, and the current sent in such a direction as to reverse the magnetism left in the magnet by a previous current of the same strength, the time required for the current to establish itself was over three minutes. The difference of time required for repetition and for reversal of previous magnetisation was also very marked when the iron circuit was closed. The results show that great errors may arise by the use of ballistic methods of experiment, especially when weak currents are used, and that for testing resistances of circuits containing electro-magnets, a saving of time may be obtained by using a battery of considerable E.M.F.

Another set of experiments gives the effect of successive reversals of the impressed E.M.F. at sufficient intervals apart to allow the magnetisation to be established in each direction before reversal began. In this set also the effect of cutting out the battery and leaving the magnet circuit closed is illustrated, showing that several minutes may be required for the magnet to lose its magnetism by dissipation of energy in the magnetising coil. The effect on these cycles of leaving an air space in the iron circuit is also illustrated. It is shown that a comparatively small air space nearly eliminates the residual magnetism and diminishes considerably the rate of variation of the coefficient of induction and the dissipation of energy in the magnet.

Several cycles are shown for the magnet used as a transformer with different loads on the secondary. The results give evidence that there is less energy dissipated in the iron the greater the load on the secondary of the transformer.

Some experiments are also quoted which go to show that the dissipation of energy due to magnetic retentiveness (magnetic hysteresis) is simply proportional to the total induction produced when the measurements are made by kinetic methods. Reference is made to the recent experiments of Alexander Siemens and others which seem to confirm this view.

The Electrostatic Capacity of Insulators.—According to determinations of M. Lagarde, the following values may be assigned to the electrostatic capacity of insulators:—

Of Willoughby Smith, W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, G.C.M.G.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz, Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), and Lord Rayleigh, F.R.S., have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

ELECTRICITY AND MEDICINE.

All progress, it may be said, has from time to time been impeded by unworthy work; and the progress of science has suffered as much as that of any other branch of learning, and this not always in its applications, but even in research itself. Astronomy, which has been deservedly called the noblest of the sciences, lapsed through astrology into the most impudent charlatanry, which survives to this day in the silliest form in certain weekly journals. The whole of chemistry was at one period swamped by a flood of delusion, that remarkable quest of the alchemists, which saw a large band of workers whom we must call scientific men, numbering, perhaps, Sir ISAAC NEWTON among them, concentrating all their powers, in their own fashion, upon the direct production of gold; the aim which, although, it may be said to underlie all commercial activity, science in its best moments is proud to disclaim. Mechanical science has its Keely motors and Marchant engines; and worthless water motors are being pushed to-day, whether in ignorance or something worse we cannot tell. Electrical science may be justly ashamed of what has been done, and what will probably continue to be done with primary batteries for electric lighting, while to many medical men the very name of elec-

Digitized by Google

tricity is abhorrent. Not only is electric light supposed to injure eyesight, and telegrams to add to the worries of life, but by electricity presumptious laymen have dared to attempt cures, and in their unrecognised methods have even repudiated either assistance or sympathy from qualified practitioners. The general public are little aware of the debt which they owe to the professional rules and etiquette which control the doctor, the architect, the barrister, and other professional men. Their rules, self-imposed, and observed not indeed to the letter, for they are unwritten, but kept with most conscientious strictness, are the safest protection both of themselves and of their clients.

Two hundred years ago electricity was first employed in medicine, and though quackery was rampant then as now, electrical treatment, being unknown, was at least free from reproach. Medical methods have been, and still are largely empirical, and the remarkable effect of electrical discharges upon both nerve and muscle suggested that some curative properties might be expected from an agent which exhibited such powerful physiological effects. But no rational or systematic use was made of it. Some accidental cures seem to have been effected, and the very ignorance of those who employed electricity, encouraged quacks to seize upon electrica treatment as possessing the valuable qualities of mystery and comparative harmlessness. A few workers on the Continent had sufficient courage to investigate a branch of medical science which had fallen into disrepute, and about forty years ago Du Bois Reymond and one or two other physiologists made real advance in purely scientific investigation, while Erb and others studied the use of electricity in diagnosis and curative effects. In this country medical electricity still remained under a cloud. With the exception of the late Dr. Steavenson and Dr. Stone hardly a single doctor in this country dared ignore the taboo which had been placed upon it by the English medical school.

Erring, perhaps, on the safe side, and with as strong a conservatism as that which forbad them to use certain drugs merely because homœopathists set a high value upon them, they have left it severely alone. One or two makers of induction coils, being unqualified men, have done something to strengthen this prejudice, especially as they claimed success, and during the last few years an honest attempt to apply electrical treatment with care and intelligence has retarded rather than assisted the progress of the subject, because several professional rules were broken, the requirements of proper qualification were not attended to, and advertising was employed, not only directly, but by the equally unprofessional action of communicating articles and papers to non-medical journals and scientific societies. So sensitive are English medical men in this matter that we shrink from devoting much attention to electrotherapeutics in these columns. The discussion of the curative properties of a new drug would be out of place in a chemical journal, though an account of its preparation might not; and we believe that the true interests of medical electricity will be best served if we confine ourselves to any matters of electro-physiology that may arise, to description of appliances, and to the review of books which are sent us. Meanwhile we believe that steady progress is being made on strictly professional lines both in hospital practice and in private treatment. All that is done in this way goes to the stock of orthodox medical science. Cases of positive cure will be received with caution and new hypotheses with hesitation, and the present prejudice and apathy will doubtless continue well into the next century, but there are ample grounds for believing that in proper hands there is a great future for the use of electricity both for diagnosis and for cure.

REVIEWS.

Medical Electricity: a Practical Handbook for Students and Practitioners. By W. E. Steavenson, M.D., and H. Lewis Jones, M.A., M.D. (London: H. K. Lewis, 1892.)

The late Dr. Steavenson who was in charge of the electrical department at St. Bartholomew's Hospital, left in the form of manuscript and a large mass of notes the material for a work upon medical electricity. These were left at his death in so incomplete a state, that, while the plan of the book has been followed, much of his valuable experience has unfortunately been lost. Dr. Lewis Jones, the present medical officer in charge of the now well-established electrical department at "Barts," has completed the work in a most satisfactory manner.

About one-fifth of the book, devoted to the elementary physics of the subject, and written in collaboration with Mr. H. M. Elder, one of the secretaries of the Physical Society, is in itself a useful little text-book of electricity, and is commendably free from lecture-room antiquities and from lists of examination questions which generally accompany electrical literature of this kind. This part of the book forms a thoroughly sound basis for the medical student or practitioner, and contains numerous references to standard text books for those who wish to push their studies further. A brief, almost too brief, sketch of the subject of electrolysis is given, and enough is said upon electro-magnetic induction to give an elementary account of an induction coil. Only a single ambiguity catches our eye, where the iron core in a coil is said to have "the drawback that owing to the sluggishness with which the iron becomes magnetised, the secondary current is somewhat retarded behind the primary." With this exception the physics are far above the ordinary standard of electro-medical writers.

The first practical chapter (Chap. IV.) relates to the apparatus used in the application of statical electricity. That either sparks or a brush discharge can have any beneficial result other than secondary effects from nervous jar and irritation is very surprising; but there seems to be a considerable amount of evidence to support it. The most important method is the application of a positive brush discharge or "souffle" as it is called as a sedative in neuralgia, St. Vitus' dance, and some forms of headache.

The next chapter describes primary and secondary batteries and other apparatus. The types are well chosen, and useful practical hints are given on the use and care of batteries. We are surprised to find that the author is not at present prepared to recommend the use of current from the mains of supply companies, and suggests that "no doubt the best method of utilising the current so supplied is to charge accumulators." This use of a continuous supply ought to be of great value to medical men, not only for accumulators, or for cautery, laryngoscopes, &c., but also for curative purposes. Dr. Jones fears that by the use of resistances to reduce the pressure to the ordinary limits, much energy would be wasted, and he gives as an example the heating of a cautery with 25 amperes, when it would be necessary to use 3·9 ohms on a 100 volt circuit, only one-fortieth of the whole energy being used. This is a rather large current, unusually large, we believe, but at 7d. per supply unit it would cost less than 1s. 6d. for an hour, or 1d. for about $3\frac{1}{2}$ minutes. Alternating currents are no doubt more useful for such purposes, and a specially arranged adjustable transformer is described. In Chapter VI., where various pieces of apparatus are clearly illustrated and described, a protest is made against unnecessary names—rheophores for electrodes and wires, rheostats and rheochords for resistances, rheotropes for commutators, and rheotomes for contact breakers. The author does well in using the well-known names for these things, but he cannot shake off the expressions faradism and galvanism, for induction coil currents and battery currents. "To apply the coil," or "the battery" ought generally to suffice, but some adjective is required to describe the "current from a coil." The word "faradic" is accepted and recognised by medical men, who neither accept nor recognise the value of electrical treatment. A "coil" current is clumsy, and the ordinary "alternating" current will not do, for the current from ordinary alternators

Digitized by Google

and transformers is an altogether different thing, and apparently of little value for medical purposes. A pair of words, "stabile" and "labile" have been adopted to denote the stationary and the stroking application of electrodes. We do not quarrel with these, as medical science is full of such terms, which have to a certain extent an international character.

The galvanometers for measuring the small currents used in medical work appear to be very unsatisfactory, even for continuous currents, while there is nothing to measure "faradic" currents with any real precision. It does not appear that medical men know whether the milliamperes of current from an induction coil play a more important part than the sudden kick of the pressure, but the "faradism" cannot be scientifically applied until it is quantitatively applied. They do try to measure their currents, however, and it is to be hoped that instrument makers will supply them with reliable instruments. The water voltameter which, it is suggested, may be used "to check the readings of a galvanometer or ammeter," is properly described as an exceedingly inaccurate instrument, "the corrections, too, are somewhat troublesome, though the method is so rough that they may be often omitted without much impairing the result." This speaks volumes for the value of the instruments which are thus to be checked. It is a pity that corrections are necessary, for, with charming simplicity, 100 milliamperes liberate about 1 c.c. of mixed gases in 10 minutes. The copper voltameter and the method of use is described, with notes on the necessary precautions.

With the physiological and pathological part of this book we are not so much concerned. Numerous authorities are quoted, the hypotheses are clearly stated, and the treatment is carefully described. Some observations are made on the flow of current in the body as a conductor, and in this connection it would appear that further attention should be paid to current density. Erb has suggested a number of standard sizes of electrodes for application to the skin. Their area in square centimetres and in inches is given, together with their diameters, but the names "small," "normal," "medium," "large," &c., are retained. The "dose" in milliamperes should be accompanied by the area of the electrode, from which the current density at the skin could at all events be found. The complicated electrical phenomena of nerve and muscle are described, together with the laws of electrotonus and muscular contraction. These have been tabulated, and are denoted by initials. K C C, for example, stands for "kathodal closing contraction," A O C for "anodal opening contraction." These symbols appear to be useful in diagnosis. The "reaction of degeneration" in paralysis is illustrated by some interesting typical curves of Erb. The use of the electric bath occupies a chapter, and the valuable application of electricity both for diagnosis and cure of infantile paralysis is discussed. In a chapter on electrolysis the destruction of nævi, and fibroids, and the treatment of strictures is described, and the volume closes with a chapter on cautery and surgical lamps. This work, which is fully illustrated, is essentially a practical handbook, and even if the chapters devoted to the curative applications of electricity are passed over with indifference by medical men, shrinking from a subject which has been tainted by quackery, they will find much valuable information on batteries, cauteries, and other surgical apparatus about which they need have no professional timidity.

The Hydro-Electric Methods in Medicine. By W. S. Hedley, M.D. (London: H. K. Lewis.)

This volume is largely a reprint from articles that have appeared in medical journals. These have little connection with each other, and the contents are not indexed. The last chapter or group, as the author calls it, deals merely with massage, and contains no more than a passing reference to electricity. The style is bright, but the general gossip is more interesting than the electro-medical part. "Roman ladies," says the author on the first page, "wore amber necklaces to cure their ailments. Was the amber necklet the prototype of some modern 'electrical appliance'? It was certainly superior from an æsthetic point of view, and could not possibly be inferior in point of electrical efficiency." The author feels the empiricism of the present state of knowledge, but seems to miss an important point in the following passage from the preface: "When our friends, the 'pure physicists,' smile (and not without reason, I admit) at the inexactness of our electrical methods, they do not always give due weight to the fact that we have to do with an animal organism, and not with a carbon filament or a copper wire." True; but even the physicist knows enough about physic to be aware of the importance of measuring a dose. Exactness in estimating the effect is desirable, but still more desirable is accuracy in measuring the stimulus.

Only one chapter deals with the subject indicated by the title, the electric bath. Some display of figures is made, but very little definite information is given about "the physics of the hydro-electric bath." The results of experiments are of some interest; in one case, the presence of a patient's body caused the flow of current to be deflected "round him and not through him," while it is recorded that in another case, "if one of the legs be held out of the water the current strength as registered by the galvanometer is reduced." The author shows that the apparent decrease of resistance and increase of current in a bath when the body is introduced, is due to the change of level of the water by displacement, and consequent increase of the sectional area. He concludes that only about 5 per cent. of the total current passes through the body. We fear that electricians and medical men will be unable to meet on common ground while the latter held such views as the following:—". . . For therapeutic purposes the alternating and continuous current may be regarded as almost two different agents. At the same time, it must never be lost sight of that the difference, strictly speaking, is one of degree—that it depends upon their being differently "cooked," so to speak, before being "served." By the time the continuous current has been run through the coil and chopped up by the interrupter, and, through inductive action, made more pungent and penetrating by the addition of electromotive force, it has become a very different thing, and 'a little of it goes a long way.'" We may be wronging the author by quoting this highly metaphorical passage, but it contains the suggestion of a real difficulty to which physiologists have paid too little attention, on which medical men have hardly troubled themselves, and on which the physicist can at present throw no light. The secondary current of an induction coil has been investigated by Blaserna and others, but no one to our knowledge has attempted to plot the curve of volts or current. The current being made more pungent by the addition of electromotive force is an expression which even a Chancery Q.C. would hardly use, but everyone can see what the author means, though no one has yet put it into scientific language.

It would be difficult but not impossible with existing methods to examine the curve of volts. The maximum can be judged by the sparking distance, the mean can be guessed from the mean current. The mean current is very difficult to measure, but we have no instruments by which the current curve could be recorded. Neither physiologists nor medical practitioners seem to know whether the volts, the current, or the coulombs is the quantity to be measured, or whether the stimulus is a complicated function of all. It is possible that sensation diminishes with increased frequency, the mean current remaining constant, but this has not yet been proved. Until these elementary matters are cleared up it is difficult to see how dosage with an induction coil can be intelligently measured.

The author seems to find great difficulties in using "the current from the main," and fears "an unexpected and undesirable increase of power," "the electro-motive force in the mains rising suddenly from some disturbing cause." The only possible way in which this could happen, if lightning be excepted, would be by the failure of his resistances, a most unlikely event if ordinary care is used, and far less to be feared than many surgical accidents. The author recommends a Cunynghame cut-out and an adjustable shunt besides adjustable resistances, but after all this complication he has nothing at all to say about "the therapeutic value of dynamo currents." A chapter on "the current that kills" is equally disappointing. Death from electric shock is compared to "a sudden fright or a blow on the epigastrium;" "we say that such cases have died from 'shock,' and we mean that the heart's action

Digitized by Google

is suddenly arrested through nervous centres," a statement which might be expected from an intelligent coroner. Another "explanation" deals entirely with the uncommon case of a discharge through the brain. The author evidently takes an interest in the subject, and we hope that on some future occasion he will put forth a more useful and methodical work.

SEMAPHORE v. MORSE.

Signalling is a strong point with the British Navy, and it in more than one respect competes successfully with the "flag-wagging" of the Army. The favourite system is the old semaphore, which was the forerunner of the electric telegraph. The semaphore alphabet is fully ten times as easy as the Morse, if this proportion can be guessed at by the time required for learning one or the other; and any of our readers who want to while away a rainy afternoon at the seaside should repair to the nearest coastguard station, where they will find competent and willing instructors in the useful calisthenic exercise of semaphore signalling. Each letter is signalled by a single attitude of the arms, either with or without flags; hence the semaphore system is far more rapid than the Morse, but it suffers from the disadvantage that it is not easily adapted for use at night.

Signalling with a flash light, using the Morse code, is often preferred, since it can be seen so much further than the semaphore, even in daytime, and can also be seen in any direction, whereas the semaphore has to be slewed round so as to face the ships in turn which have to take in the signal. Taking about three miles as the limit of use of an ordinary deck semaphore in daytime, it is satisfactory to know that they can be illuminated so as to be used at night at about 1¾ miles; but they cannot compete for distant signalling with the flashing light which can be seen over 15 or 16 miles. Some difficulty was found in illuminating a semaphore so as to be seen at any distance at all at night; and the first idea was to build one like a star, with eight fixed arms, studded with incandescent lamps, any arm or pair of arms being switched on at will, the switch handles being worked similarly to the mechanical handles in daytime. The chief objection to this form of semaphore was that it was unsightly and unweildy, very liable to damage, and was only of use at night, and at the same time was considerably slower than the one used in daytime for two reasons—one being that the incandescent lamps took an appreciable time to attain and lose their full incandescence, and the other that the eye could not follow the arm. In daytime the eye follows the arms, and instinctively the letter is read as soon as the arms stop. With the star semaphore the whole semaphore was lost to view when the lamps went out and a complete letter was presented to the eye; this necessitated making the signal slower. The semaphore at present in use simply consists of the day semaphore with a square looking-glass reflector, with four 50 c.p. glow lamps fixed about two or three feet in front of the centre. This arrangement is satisfactory if the intensity of light on the arms is carefully adjusted. If the arms are painted white and all four lamps used, at a distance of about half a mile, the whole appears a blaze of light, and the motion of the arms cannot be distinguished. This is only natural, since near the centre of the arms the light is most intense, and at the same time the arms are closed together, and therefore a large apparent circle of light is reflected with the bare tips of the arms only distinguishable beyond it. It is inconvenient to have several reflectors and so distribute the light more evenly, but good results are obtained merely by painting the arms so as to graduate the reflection. For a radius of about one foot the arms and post should be dull black, then for another foot radius, red, and beyond that, white. By this means an approximately equal intensity of light is reflected from each part of the whole surface of the arm. The light required, as a rule, is not more than three 16 c.p. lamps. Methods have been tried to use the search light beams as semaphore arms, but at present have failed, chiefly owing to reflecting only a portion of the beam, and which small beam has not sufficient density to enable it to be seen at any distance on a clear night with a good arc. Even the whole beam of a 100 ampere light is a not very visible object; and if a semaphore of the kind is to succeed, the whole of the light must be used to form the two arms. Again, all letters involving the position of the arms below the horizontal are lost to sight at a short distance, unless the projector be placed in the top, or in some very high position.

Experiments have been made at Devonport on board the "Defiance" torpedo school ship. An ordinary search-light was fitted with a metal screen, so arranged as to either obscure the light altogether or allow it to be visible through narrow slits in the screen. The position of the slits represent the letters of the semaphore, and the beams passing through them are expanded by the reflectors. The experiments were interfered with by mist and rain, though we are not informed whether signalling by simple Morse flashes would have suffered to a greater extent. If the vertical system of lighthouse illumination, which was discussed some months ago, were really practicable, two radial beams might be easily contrived by means of a pair of mirrors, but, as in lighthouse work, such beams would only be visible under certain conditions of light haze. In addition to its speed the semaphore system presents the advantage that mistakes are far less likely to occur, since it is impossible to run two letters into one; a *t* and an *r*, for example, frequently appear as *c* in ordinary telegraphy.

As so many of our readers are familiar with the Morse code the semaphore code which we give below may be interesting to them. The first signal, Fig. 1, means "Alphabet," or "Attention," or "I want to speak," and at the same time shows the direction of the right and left hand of the signaller; since the semaphore, whether worked by the movement of the arms, or with a mechanical arrangement, is often liable to be read from behind as well as from in front. In the mechanical semaphore a small supplementary arm (Fig. 2) is generally fixed during a message to show the direction. "Flag-wagging" in the army is generally carried on by two men; one facing the distant signaller reads the messages, while the operator stands facing him, and with his back to the other station. There is no such right and left-handedness in heliograph or Morse flashing, and very little difficulty is experienced in semaphore work from this cause. The following diagrams represent the positions as seen, the two operators facing each other. The signal (Fig. 3) means that the following signals are to be read as numerals. It is not at all difficult to read a message from behind. It would seem that semaphore signalling might be carried out by three lamps, one to represent the centre round which the arms revolve, and the others the extremities of the arms. The former might be coloured, or rather less bright than the latter.

Alphabet

Fig. 1.

Fig. 2.

Numerals

Fig. 3.

This reminds us of the Kelway system of signalling which was shown at the Naval Exhibition last year and at the Crystal Palace. A number of glow lamps were arranged on a board, and by suitable wiring the depression of keys illuminated a sufficient number of these lamps to trace the outline of a letter. The only possible advantage of so cumbrous a device is, that it is legible by a perfectly uninitiated person. It was difficult indeed to see what use could be found for it; but an opportunity was afforded during the recent elections, when this system was used to signal the results to a crowd outside the National Liberal Club.

An attempt has been made, but at present with but little success, to introduce the semaphore system among the engineering staff of one of the principal railway companies. The "gaffer" could thus easily give orders to a man at a quarter of a mile or so.

Digitized by Google

It is interesting to find that although the Morse code has become so common in all parts of the world, and is so applicable to needle instruments, sounders, printers, flashing, whistling, flag-wagging, tapping against a wall, winking, or kicking under a table, the semaphore should still hold its own, especially in the Navy. The alphabet is arranged in Fig. 4 in four sets of signals. In the first only one arm is used, in the second the right arm is at 45° below the horizontal, in the third it is horizontal, and in the fourth it is at 45° above the horizontal. The initial letters of these four series spell "a hot." The sequence of the signals greatly facilitates the memory. The letter M is rather difficult to remember, but L and N are easy, and M can be easily arrived at from either of these.

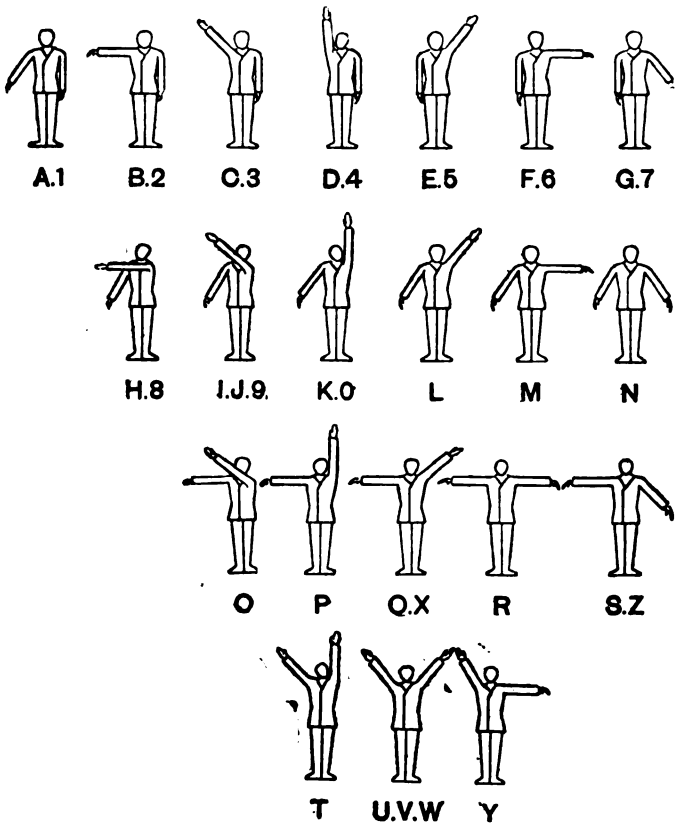

Fig. 4.—Semaphore Code.

The following additional signals have been lately introduced; they are given separately so that the symmetry of the main set may not be spoiled :—

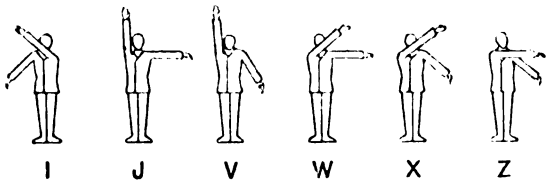

Fig. 5.—Additional Signals.

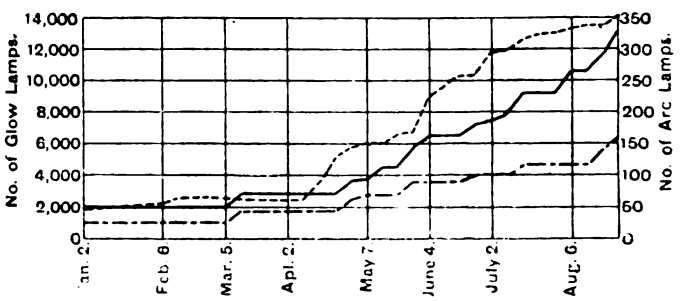
The much talked of search light on Mount Washington came into operation a few weeks ago. The light was designed by Mr. Lewis H. Rogers, of the Thomson-Houston Electric Company, who was anxious to see what search lights could do at such an altitude. With the co-operation of the various railway companies and hotels the plant was erected at a cost of $7,000, a tower 55ft. in height being built on the highest peak of the mountain. The projector stands on the highest part of the tower, and its movements are controlled by means of electric motors in a room below. The current is generated in the basement of the tower by a 100-ampere dynamo, driven by a 15 H.P. engine. The light at the lamp itself is stated to be 20,000 candles, but when projected into space from a Mangin mirror, 30in. in diameter, it is said to be increased to 100,000 candles. If, however, the beam is practically parallel as it should be for greatest penetration, the estimate of its candle power becomes meaningless, it would be infinite. Messages have been sent from Mount Washington to Portland by the Morse alphabet, and were easily read. The account given in the *Tribune* of these experiments is not very intelligible, for it puts the distance at 85 miles and says that as the source of light was far below the horizon, the beam was projected into the sky at an angle of 45 degrees. "In this way the lower strata of the clouds were avoided, and the pencil of rays was given a path that took it to a point probably 80 miles in the air above Portland, its length being calculated to be fully 110 miles." There are several discrepancies here. Mount Washington appears on the map to be less than 70 miles from Portland, and is 6,266ft. in height. The distance of the horizon from this altitude, without allowing for refraction, is about 110 miles; and a height of only 2,500ft. commands over 70 miles. However, it appears from further details that only the "sky flashing" was used, and the experiment is certainly of great interest.

THE CITY LIGHTING.

The popularity of graphic methods is evidently on the increase, for we now have a public company presenting the main facts of the year's operations to its shareholders, not by means of a wearisome array of tabular statistics, but in the shape of curves. The three diagrams which we publish below have been reproduced from some which are appended to the report of the proceedings at the second Annual General Meeting of the City of London Electric Lighting Company. These curves are of the simplest possible character, but we may hope, as time goes on, to



(Upper) ..... Progress Curve for Private Lighting (both Stations).
—— Progress Curve for Public Lighting (both Stations).
(Lower) ..... Progress Curve for Public Lighting (Bankside).

Fig. 1.

see others added somewhat more interesting and instructive, though perhaps more complicated; such, for instance, would be curves showing the number of units generated and metered each month, and the average number of pounds of coal consumed at different times of the year per unit sold. The idea is an admirable one, however, even if imperfectly carried out owing to the natural desire not to "give oneself away" by imparting too much information to the public at large and to possible trade rivals, and we trust that similar curves will in future be a feature of all reports emanating from the offices of electricity supply companies. Should the example set by the City of London Company be generally followed Mr. Crompton's demand for figures will be in a fair way of being met.

Turning to the curves of the City of London Electric Lighting Company we see from Fig. 1 that at the end of last month close on 350 arc lamps were connected up, or over 87 per cent. of the total number contracted for; at the present moment practically all the arc lamps under the City contracts are in operation. From the same diagram it will be seen that the private lighting has been rapidly growing, the total number of 8 c.p. lamps connected to the Company's mains at the end of August being 14,000. Figs. 2 and 3 show at a glance the financial status of the Bankside and Wool Quay stations respectively. As was only to be expected under the circumstances, the outgoings have considerably exceeded the incomings during the greater portion of the year. About the middle of July, however, the income curve of each station took a plunge, and crossed the expenditure curve, and since then the two curves

Digitized by Google

appear to have been in a state of unstable equilibrium, in so far as their relative position is concerned. The dark days and King Fog will, however, doubtless soon dissipate the apparent hesitancy exhibited by the income curve in getting the upper hand of the curve of outgoings.

It is interesting to note that the Chairman, in his speech to the shareholders of the City of London Company, at the recent meeting, alluded to the special measures which had been or were about to be taken to obtain early information of the approach of fog. The Docks Committee it seems has promised to telegraph from the docks when fogs come up the river, and the placing of observers on elevated points around London in telephonic communication with the generating stations was also mooted. If fogs as a rule came down upon us like a tidal wave, these precautions would doubtless suffice; but if there

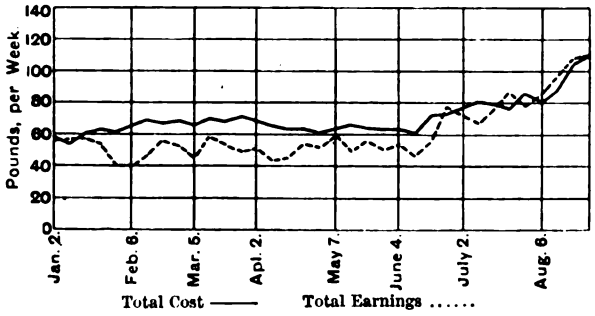


Fig. 2.—Bankside Station.

is anything more characteristic about a London fog than its colour and persistency, it is its frequent suddenness and sporadic distribution. Darkness rivalling that of midnight often supervenes within five minutes of comparative brightness, and as often as not passes away in thrice that time. These trying and

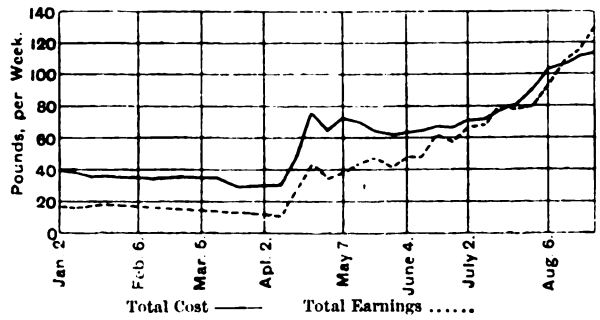

Fig 3.—Wool Quay Station.

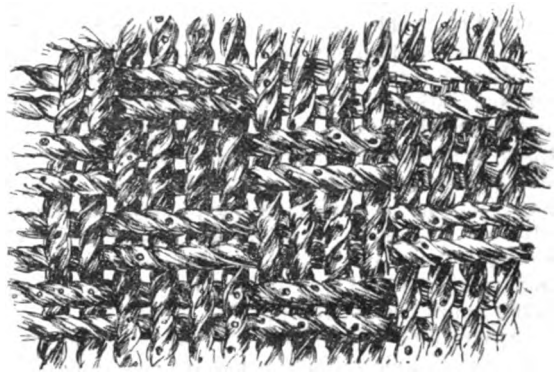
peculiar conditions may be expected to give rise to ingenious expedients; but telegraphic fog warnings do not seem to us to promise anything like a complete solution of the problem.

It is interesting to note in this connection the different attitude assumed towards fogs by gas and electric light engineers. For a gas works manager a sudden fog has no terrors; all he dreads is persistent darkness, exhausting his reserves of gas. The central station engineer, on the other hand, has no storage to speak of, his only reserve is idle machinery, of which he has generally enough and to spare; hence fogs of long duration, provided no hitch occurs in the coal supply, are a positive boon to him, while a sudden darkness is his *bête noir*.

THE COLGATE SECONDARY BATTERY PLATE.

Although so very few new types of secondary battery plates ever come into commercial use, and in spite of the comparative disfavour of secondary batteries in America, a never ending stream of patents issues from the United States Patent Office, and hardly a week passes without some strange form of plate being illustrated and described in the columns of the technical press. The vast majority of the patentees aim at a light plate having a large active surface exposed to the electrolyte, regardless, perhaps, of the fact that if everything is to be sacrificed to these two considerations nothing can surpass a "lithanode" plate. As a sample of what is being done across the Atlantic we illustrate below the plate devised by Mr. Arthur Colgate of New York, which was described in the *Electrical World* of September 3. Its construction can be seen from the accompanying illustration. Long, narrow thin strips of lead are formed and then passed through a machine which perforates them, forms two longitudinal corrugations in them, and then twists them together with a rope of asbestos. These strands are next woven into a loose mat, such as is shown in the figure. Several of these mats are then put together under moderate pressure so as to form one plate, which is then inserted in a lead frame and is ready for use in the battery. The cell from which these details are taken is composed of four plates with a total weight of 8lbs. Each one of these plates is composed



of three mats 6in. by 8in. pressed together. The plates are $\frac{3}{32}$in. in thickness, and are separated by a space of about $\frac{5}{16}$in. The surface exposed amounts to 72 square inches of surface to each square inch of floor space occupied by the cell.

CONTINENTAL INCANDESCENT LAMPS.

A short time ago, writes Mr. C. J. Robertson, of the Elektrische Glühlampen Fabrik "Watt," I called attention to the recent English and American lamp tests as showing results far inferior to the older Vienna tests of continental lamps. Knowing from day to day what progress has been made in lamp manufacture on the continent since the latter tests were made, I was in a position to claim superiority for the continental lamps over the English and American ones; but I was not in a position to quote any independent figures. Since then, by the courtesy of Messrs. Ganz and Co., of Budapest, I have had the opportunity of examining and (through Mr. Déri) of publishing the following extract from a Report of the International Electric Company of Vienna to Messrs. Ganz and Co., of Budapest:—

"August 27th, 1892.

"The 15 glow lamps which the factory 'Watt' let us have for trial purposes were tested and gave the following values:—

Hours.	Average energy in watts.	Average c.p. in normal candles.	Life in hours.
0	49·75	16	1 lamp 55 hours.
50	49·70	16	1 „ 912 „
260	49·70	16	1 „ 1,080 „
670	49·60	15	1 „ 1,368 „
1,150	49·40	14	1 „ 1,660 „
1,730	49·00	12·5	1 „ 1,680 „
			1 „ 1,850 „
			The remaining 8 lamps still burning.

"(Signed) M. Déri,
"*Director.*"

For the sake of comparison I give a table below, wherein I have worked out the average watts per candle, and the mean

Digitized by Google

percentage of original candle power, in order to compare them with the recent Ohio tests (See *The Electrician*, July 29) of the best American lamps :—

Hours.	Average watts per candle.		Mean percentage of original c.p.	
	"Watt" lamps.	G American lamps.	"Watt" lamps.	G American lamps
0	3·11	4·20	100 per cent.	100 per cent.
50	3·10	4·40	100 ,,	97·5 ,,
260	3·10	4·95	100 ,,	88 ,,
670	3·30	5·90	94 ,,	71 ,,
1,150	3·53	6·75	87·5 ,,	61 ,,
1,730	3·93	—	78 ,,	—

In the above table the lamps of 3·11 watts per candle should have changed their efficiency and candle-power at a far more rapid rate than those taking 4·2 watts per candle, if they had been equally well made. If the above lamps were considered to be "all out" when they had only dropped 22 per cent. from their original candle-power, then their average life would have been 1,280 hours for an average of 49·5 watts and for an average of 14·75 candles, whereas the American lamps would have been "all out" at 260 hours and taking an average of 72·6 watts and giving an average of 16·1 candles. On the basis of an average of 16 candles at the same watts per candle, this would, with the "Watt" lamps, be equal to an average life of 1,280 hours for an average of 53·7 watts.

The above results will answer the following points which several of the chief electrical papers have considered desirable of attainment on the part of lamp manufacturers :—(1) the production of a lamp which for a life of 1,000 hours should give an average of 16 candles for 56 watts ; (2) the production of a lamp which shall not vary much in illuminating power during its useful life, this object being even worth attaining at the expense of a slightly lower efficiency.

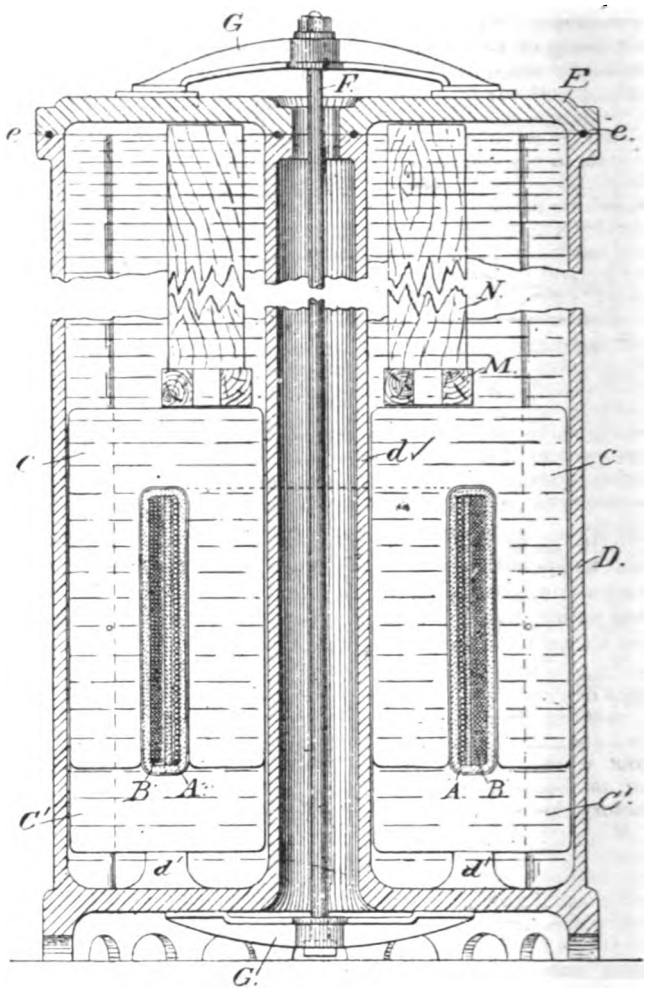
So much for a continental make of lamp of normal candle-power, taking at the start a normal number of watts per candle. On the other hand, Messrs. Siemens and Halske have been carrying out tests on some so-called "high efficiency" continental glow lamps (make not specified), requiring only 1½ to 2½ watts per candle with the results given in the accompanying table :—

Hours from start.	Watts required by lamps of		
	1½ watts.	2 watts.	2½ watts.
0	1·52	2·01	2·51
5	1·91	2·03	...
10	2·43	2·24	2·52
15	2·81	2·38	...
20	3·19	2·48	2·52
25	3·40	2·57	...
30	3·77	2·71	2·52
35	4·07	2·91	...
40	4·15	2·98	2·55
45	4·25	3·03	...
50	4·45	3·06	2·69
55	4·46	3·25	...
60	...	3·46	2·71
65	...	3·51	...
70	...	3·65	2·79
75	...	3·67	...
80	...	3·83	2·89
85	...	3·93	...
90	...	3·99	3·01
100	...	...	3·09
110	...	...	3·22
120	...	...	3·26
130	...	...	3·30
140	...	...	3·53
150	...	...	3·58

After ten hours the 1½ watt lamp is therefore more expensive to run than the 2 watt lamp, and the cost of the latter exceeds that of a 2½ watt lamp after 25 hours.

THE PYKE AND HARRIS OIL TRANSFORMER.

This transformer is constructed with all, or as much as possible, of the mechanical insulation of a permeable character. The transformer itself (see Figure) is placed in a corrugated container of earthenware D, serving at the same time as a cooling vessel, the height of which is about three times that of the transformer proper. The transformer consists of concentric coils of wire A and B, arranged so as to form a ring, which is arranged in sections, sepa-



rated from each other by porous insulating material which can be easily penetrated by the insulating liquid. The coils are held together by the iron of the transformer, C C and c' c', which is arranged in saddle-pieces placed vertically and radially, so that each set of plates enters one of the corrugations of the vessel. Each horseshoe plate encloses on each side a radial section of the coil. Each set of saddle-pieces is applied to the coil alternately from the top and from the bottom, and secured by corner bolts. The earthenware pot is provided with an axial tube, *d*, reaching to the top of the vessel. India-rubber packing rings, *e*, are placed in circular grooves between the vessel and the lid E. Washers, G G, connect the bolt F with the vessel and lid. An insulating ring, M, is placed in the top of the transformer.

Electro-Medical Apparatus.—In a recent communication to the Académie des Sciences, M. J. Morin described a new form of medical coil. After pointing out that in the ordinary form of induction coil where the primary is slid longitudinally into the secondary or where a closed conductor passes over the iron core, there is apt to be a sudden change of current strength possibly injurious to the patient, he shows how this may be overcome by constructing two flat coils side by side, one of which could be revolved into a plane at right angles to the other coil. It will readily be seen that in revolving through this angle the induced current gradually passes from its maximum to its minimum value. The author also points out how this arrangement may be utilised for converting a continuous current into a sinusoidal alternate current for electro therapeutic purposes.

ON THE APPLICATIONS OF ELECTRICITY IN THE ROYAL DOCKYARDS AND NAVY.*

BY HENRY E. DEADMAN.

This is an age of electricity ; and the fact is well exemplified on board a model battle-ship of the Royal Navy. Some of the applications of electricity in the naval service do not come within the scope of ordinary mercantile practice ; and in the case of those which do, the naval experience is of a special kind, and may be of some value to those outside the service. A statement, therefore, of naval methods and practice up to date may not be without interest and instruction to the members of this Institution. At the present ime visitors to Portsmouth Dockyard will probably be surprised, not disappointed, at the somewhat primitive character of the workshops devoted to the electrical testing and construction. This branch of work was commenced in a very small way about seventeen years ago, and found a temporary home in a small shed which had been previously used for a different purpose. As the work from time to time has grown, this shed has been enlarged as far as available space would permit. Designs have been prepared for a more substantial and suitable building, in the hope that in time the Admiralty will be able to devote sufficient money to providing a proper habitation for this important branch of dockyard work. The larger proportion of the plant required for electric installations in the navy is not made in the dockyard. Formerly all dynamos and their engines were obtained entirely by contract ; but recently five sets of these have been designed and constructed in the dockyard. After patterns of the smaller fittings have been fixed, the supply of these also in bulk has generally been obtained by contract. There is, however, a great deal of work left to be done in the dockyard, in testing and installing these fittings in the ships, in carrying out repairs, and in devising and preparing patterns of new fittings to meet the constantly growing requirements of the navy. There is also some work, which for obvious reasons is confined to the royal workshops. The applications of electricity in the navy may be dealt with under the following heads :—(1) search lights ; (2) internal lighting of ships, including temporary installations in ships building and repairing ; (3) torpedo and gun circuits ; (4) electric communication ; (5) other applications.

Search Lights.

The introduction of the search light, without which no modern war ship or torpedo boat would be considered complete, dates from 1876 ; and the first vessel in the navy fitted with a search-light apparatus was the "Minotaur." Some experiments had been carried out in the previous year by Messrs. Wilde and Co., of Manchester, on board the gunboat "Comet ;" and these proved so far satisfactory that a complete plant was ordered and fitted on board the "Minotaur." The dynamo employed was one of the alternating-current type, with 32 magnets, and it was driven at about 400 revolutions by a belt from an auxiliary pumping engine. The projector was of a primitive type, and pedestals were fixed in three different places, from any one of which the same projector could be used. It was fitted with a parabolic reflector and with dioptric and diverging lenses. A diaphragm was also provided for enabling flashing signals to be made. The lamp employed was Wilde's, and was a vertical one. The carbon rods were square in section, and their holders were made to slide on two pillars, and were moved up and down by a central pillar with a screw thread cut in it. The lamp was hand regulated, and one lead was put to earth. The "Téméraire" in the same year was next fitted in a similar manner, with the exception that a Mangin projector was introduced, fitted with Wilde's lamp, lens, &c. In the next year, 1877, the "Dreadnought," "Neptune," and several other vessels were fitted with the same class of apparatus. In 1878 direct driving was first introduced. In this year Messrs. Wilde and Co. coupled their machines to engines made by Brotherhood and by Chadwick, of Manchester. The dynamo was also improved, so as to be able to maintain two arc search lights at one time. In the same year also the "Triumph" was fitted by Messrs. Siemens Brothers with a search-light installation. The dynamos were four in number, of horizontal type, arranged in two pairs, and each connected in parallel to one circuit. A switchboard was fitted, for enabling any two of these dynamos to be coupled up together on any circuit. It consisted of a wood base with two sets of bars at right angles to each other, one set on the top of the base and the other underneath. One set of bars was connected to the dynamos, and the other to the circuits. At their intersections these bars could be connected as required, by means of suitable plugs. The projector used was a Siemens holophote, which was heavy and clumsy, being made largely of cast iron. It was fitted with diverging and dioptric lenses ; of these the latter was composed of concentric glass rings of triangular section, held in a metal frame. It had also a flashing arrangement. The lamp used was one of the Siemens self-regulating type, and had a small mirror fixed to it. It was complicated, and frequently got out of order. The carbons were apt to stick together, and the lamp was sensitive to any slight variation in speed of dynamos. This lamp did not come into general use. Subsequently the Gramme dynamo was introduced for search lighting by Messrs. Sautter Lemonnier, of Paris ; and in 1881 the "Inflexible" was fitted with this dynamo. In this installation the Mangin projector was used, with a Mangin mirror instead of the dioptric lens. The lamp was hand regulated and inclined. The Gramme dynamo has since been superseded by others of later make ; but the Mangin mirror and the inclined hand lamp survived, and became the standard service fittings.

Naval Service Projector.—Out of these earlier attempts the modern naval service projector has gradually been evolved, which has now become familiar to most persons. It consists of a cylindrical lantern made of very thin steel, with a silvered glass parabolic mirror at the back end, in the focus of which an arc light is produced between two carbon sticks, held in what is known as an inclined hand lamp, the carbons standing at an angle of about 70deg. to the axis of the mirror. The feeding of the carbons is not automatic, but is accomplished by hand ; and the lantern is so suspended that it has motion on its pedestal through the whole circle in azimuth and through about 60deg. in altitude. During its motion the electrical connections are kept up by suitable rubbing contacts. A switch is fitted in the pedestal for switching the current on and off. The circuit wires, main and return, are brought from the main switchboard to the switch on the pedestal, thence to the rubbing contacts; and finally pass close together up one of the hollow arms of the lantern support, and through the trunnion bearing to two springs at the bottom of the lamp box. The lamp when put in makes contact with these springs, and completes the circuit through the carbons. Two sizes of these projectors are used in the naval service, a larger with a 24in. mirror for ships, and a smaller with a 20in. mirror for torpedo boats. The parabolic mirror in these projectors converges the rays into a powerful and penetrating cylindrical beam of light. At the front end of the lantern diverging lenses can be attached for spreading the beam over a larger surface when desired ; or a flashing screen can be affixed for signalling purposes. The two most important parts of these projectors for the production of a good and steady beam are, of course, the reflecting mirror and the carbons. For the supply of these articles the naval service was until recently dependent entirely upon French manufacturing firms. The Admiralty, fully alive to the dilemma in which this country might under certain circumstances be placed, have sought to induce English manufacturers to enter into competition with the French firms for the supply of these articles ; and everything of this kind which has been offered with the slightest promise of success has been fully and carefully tested at Portsmouth. The English manufacturers have no doubt had no easy task to accomplish ; for, disregarding cost, the French mirrors and carbons left nothing to be desired, and are still the standards to which all others are referred.

Mirrors.—As regards mirrors the qualities required are three :—first that they shall project a cylindrical, sharply defined, and homogeneous beam of light of great intensity and penetrative power ; second, that when in operation they shall not be liable to crack by contact with water, in the form either of rain or of sea-water spray, or by a blast of cold air ; third, that they shall resist the concussion caused by the discharge of heavy guns. These qualities should be combined at a moderate cost if possible, although efficiency is the primary consideration. Thus far mirrors have been submitted for trial by six different English makers, and by others specimens are being prepared for future trial. From among these at least one successful English specimen has been obtained, which compares in all points favourably with the French production ; and one half of the supply for the navy will this year be ordered from the firm producing this specimen.

Carbons.—With regard to English carbons the results were for a long time disheartening ; even after several attempts by the same firm, none of the specimens submitted for test approached in efficiency those of the French make. The three qualities required in good carbons are that they shall maintain a steady arc without flaming or excessive hissing ; that they shall be perfectly pure and homogeneous in structure, and shall preserve a well-formed crater on the positive carbon and a well-formed point on the negative ; and that the waste shall be steady and uniform, without cracking or crumbling. A certain amount of success has already crowned the persevering efforts of English manufacturers. Although the English carbons are not even yet fully equal to those previously obtained from France, it is hoped they will soon come sufficiently near that standard to make them acceptable for use in the navy.

Projector requirements.—The present service projector requires at least one man close to it to direct the beam of light in any desired direction, and also to feed and adjust the carbons as necessary. This is a disadvantage, because the position of a search light is evidently one affording a good mark for an enemy's fire, and is a bad position for observing the object illuminated ; and it would

* Paper read before the Institution of Mechanical Engineers, Portsmouth, July, 1892.

Digitized by Google

be an advantage if the projector could be entirely manipulated from a protected position at some distance—for instance from the ordinary conning tower. For this purpose two requisites are necessary: first, a good automatic lamp; and second, an efficient motor for giving the necessary movements to the projector. It is to these two improvements that attention is now being given. A good practical automatic lamp is the first necessity; without this a man must be stationed at the projector to feed the carbons, and being there he can also direct the beam of light. Several automatic lamps have been tested, but none have as yet been adopted for general use. One lamp, in which the carbons are regulated by a small electric motor in a shunt circuit, is promising; but in its final form it has not yet been returned from the makers. The field, however, is still open for invention in this direction. Experiments have also been made with an electric motor attached to the service projector, by which the movements of the latter can be directed and controlled from a distance. The results are highly satisfac-factory, but, as already stated, the invention is not likely to be brought largely into use until it can be combined with a satisfactory automatic lamp. Recently a wheeled carriage has been introduced for using a ship's projector on shore.

Incandescent or Glow-Lamp Lighting.

Electricity is at the present day largely resorted to for the purpose of lighting internally the vessels of the navy; all the larger vessels, such as battle ships and first and second-class cruisers, are now so lighted. Moreover this mode of lighting is not restricted to the habitable portions of the ship, but is carried out to the complete exclusion of other modes, although the latter may be fitted as a reserve. Thus the electric lighting is extended to machinery spaces, coal bunkers, magazines, shell rooms, store rooms, gun quarters, &c., as well as to the illumination of compass cards, telegraph dials, bow and mast-head and signal lanterns, semaphores, &c. Clusters of glow lamps beneath an enamelled metal reflector are also employed for lighting the upper deck, when coaling or other operations are being carried on at night. In a large battle-ship like the "Royal Sovereign" there would be about 800 of these glow lamps, necessitating for this system alone about eight miles of electric leads, which are equivalent to something like 155 miles of copper wire of varying sizes, principally No. 20 legal standard wire-gauge or 0 036in. diameter.

Progress.—The first installation of internal lighting in the Navy was carried out on board the "Inflexible" in 1881 by the Anglo-American Brush Company. It was a combined system of arc and glow lamps. The dynamos used were of the Brush type, of which the first specimen brought to this country was purchased by the Admiralty, and is still in use in Portsmouth dockyard. Each machine was capable of maintaining 16 Brush arc lamps of 2,000 c.p. each. The lamps had double sets of carbons, each pair burning eight hours. These arc lamps were switched on and off by a switch opening and closing a shunt circuit of small resistance. With this plan it is evident a lamp could not be safely handled while the current was on, even if the light was switched off, because the lamp itself still formed a part of the circuit. A switch was accordingly devised in the dockyard, by means of which the lamp could be cut completely out of the circuit. The Swan glow-lamps were fitted in sets of 18 in series, each set being placed in parallel between the main circuits of the arc lamps. Each glow lamp was fitted with an automatic cut-out, bringing into the circuit a resistance equal to about that of the lamp, in case the latter failed. This system now no longer exists in the "Inflexible," an installation on modern methods having been substituted for it. The five Indian troopships were next fitted throughout with glow lamps by the Edison Company, who used the Edison-Hopkinson type of dynamo giving a current of 180 amperes at 110 volts. The "Polyphemus" was also entirely fitted by Messrs. Siemens, and the "Colossus" by the Brush Company, the dynamos in the latter being of the Victoria Brush type. The "Polyphemus" was the only ship in the navy fitted on the single wire-system. Afterwards the adoption of internal lighting became general; all new vessels except the smaller cruisers were fitted, as were also the previous vessels on the first opportunity of their coming in for repairs and refit. There are now in the navy about 300 vessels either fitted or being fitted with electric lighting, for search lights or internal lighting or both.

Difficulties.—The earlier installations, although quite satisfactory so-far as the illuminating effect was concerned, were certainly not satisfactory in regard to the endurance of the plant; in fact they were a constant source of trouble, both the dynamos and the leads requiring frequent repairs or renewals. These troubles arose partly from faulty construction, and partly from the conditions neces-sarily existing on board ships of war, such as the necessity for placing the dynamos well down in the ship, and under protection from shot; which relegated them either to the engine room with its high temperature and moist atmosphere, or to some other confined and ill-ventilated spot. Under these conditions the insulation soon suffered, and the machine quickly got out of action. The leads throughout the ship suffered too from access of salt water, which caused much trouble by destroying the insulation, and producing short circuiting, thereby frequently setting on fire the wood casing in which the leads were laid, or any other inflammable material in the neighbourhood.

Remedies.—Nearly all these difficulties have in the course of time been surmounted. While it is still necessary to place dynamos under protection for use in action, it has now become the practice to fit an additional dynamo, capable of running all the lights generally required at one time, and to place it with its motor in an open space between decks, or on the upper deck suitably sheltered. This is known as the peace or daylight dynamo. The introduction of lead-coated wires marked an epoch in ship-lighting; and these wires are entirely used in all the later installations, and are taking the place of the old leads as fast as the latter require renewal. These cables dispense entirely with the wood casings previously used, resulting in greater simplicity of fitting as well as increased efficiency. The wood casings are still used in America, even with the lead-coated cables; but in the writer's opinion, while adding largely to the cost of the installation, they are likely to detract from its efficiency, as they form such convenient receptacles for water to lodge in.

Dynamos.—The Admiralty have not adhered to any one particular kind of dynamo; for although those of the Siemens type predominate in the navy at present, nearly all the well-known makers are represented—such as Latimer Clark, Muirhead and Co., the Electric Construction Corporation, the Silvertown India-rubber Company, Goolden and Co, Crompton and Co., and Parsons and Co. The experience gained in the testing and use of these machines of different types was of immense benefit in enabling those points to be discovered in which dynamos are most likely to fail, and in suggesting the direction which improvements should take. The weak points in most of the machines supplied were imperfect insulation, owing to want of sufficient care in building: and the excessive internal heating of the armature. In some cases the section of copper used was too small, resulting in the heating of the dynamo and the rapid destruction of the insulation. By direction of the Admiralty a design was prepared by Mr. Lane, electrician of Portsmouth dockyard, for a machine to give an output of 400 amperes at 80 volts, which should embody the experience already gained, and should be free from the faults previously mentioned. Five machines have been built from this design, two of them for the "Rupert," a vessel now under reconstruction. No opportunity has yet occurred for testing them under the conditions of sea service; but two have been used for about a year under full load as temporary lighting plant for ships building, &c. At times, too, they have been worked for long periods above full load, from 420 to 430 amperes; and they have always given perfect satisfaction. They are driven at about 330 revolutions a minute by open vertical compound engines of 56 I.H.P., designed and constructed in the Chief Engineer's department of the dockyard. The total weight of the dynamo and engine with bedplate is about 5½ tons.

Other Fittings.—As regards the other fittings required to complete a successful installation—such as switches, fusible cut-outs, lamp-holders, shades, and their holders, &c.—patterns have been adopted or devised in accordance with accumulated experience, to meet the special requirements of the navy; these are simplicity, combined with strength to withstand the rough usage necessarily experienced on board a fighting ship. The guiding principle in the present installations is to make every part of the circuit inaccessible to water, by employing lead-coated cables, and by enclosing in metallic water-tight boxes all the principal switches and cut-outs, and by effecting in all cases in the interior of water-tight distributing boxes the subdivision of the mains, which themselves pass into the boxes and their subdivisions out of the boxes through water-tight stuffing glands.

Switchboard.—With several dynamos and a combined installation of incandescent and search lighting, a good switchboard is a necessity. The one generally used in the navy at present is susceptible of improvement; and a new switchboard has just been designed and made by Mr. Lane, the dockyard electrician, which promises to fulfil all the requirements.

Temporary Installations.—The employment of temporary installations of electric lighting in ships building and repairing has been a marked feature of recent practice in Portsmouth dockyard. Probably more has been done here in this respect than has been attempted in any other royal dockyard or private shipbuilding yard in the country, although these are now finding it to their advantage to follow the lead. So highly satisfactory have been the results of the experiments in this direction, that, with the exception only of the smallest ships, the electric light is now installed as a matter of course on board every new vessel at an early stage of its construction, and also in all vessels where repairs of any magnitude are to be carried out. The character of these temporary installations varies with the circumstances of each case. Where vessels are building in the docks adjacent to the electric shop, it is, of course, more convenient and economical to supply the current from

Digitized by Google

a dynamo in the shop itself, the leads being carried to the ship on temporary wooden poles put up for the purpose. Vessels building on the slips, which are too far from the electric shop to convey the current to them in an economical manner, are served by a dynamo and motor placed at some convenient spot near the ship. After a vessel is launched, and generally for all vessels afloat, the most satisfactory method is to place a dynamo and engine with a steam boiler in the ship itself, generally in a temporary wooden house on the upper deck. By this means the light is maintained without interruption during the many movements of the vessel about the basins. The leads, lamps, &c., are fitted roughly. The cables are simply tied to clips fastened to the beams, &c. The switches are hung from the cables. The lamps, with their holders, are secured to wooden bases, and protected by wire guards without any glass globes.

Cost.—Although no exact comparison can be given between the cost of this mode of illumination and that of the old plan of lighting by candles, it is estimated that in a first-class cruiser like the "Royal Arthur" the total cost of the electric lighting during the whole period of building, including depreciation of plant, would be about £1,200. This would probably not much exceed, if at all, the cost of candles for the same period; but the vastly superior illumination obtained by the electric light—enabling work to be done better, more quickly, and under better supervision, to say nothing of the advantages in health and comfort to the workmen—would justify the continuance of this system, even though the actual cost should be much greater than that of lighting by candles. It is hardly an exaggeration to say that the excellent results as regards celerity and cheapness of construction, which have lately been attained in Portsmouth dockyard, could scarcely have been realised without the aid of the admirable illumination afforded by the system of incandescent lighting.

Testing of Dynamos.—Before acceptance from the makers all the dynamos purchased by the Admiralty are tested on receipt at a dockyard; and as no less than 150 have been tried at Portsmouth during the last two years—1890 and 1891—the experience gained has been considerable. At the north end of the electric shop a space is fitted with cast-iron holding-down plates, of sufficient area to take several sets of plant at one time; and also with an overhead traveller for lifting. Steam at 100lb. per square inch, or other pressure required, is supplied by three boilers of locomotive type in the adjoining boiler-house. Adjacent to the holding-down bed is a separate enclosed room, containing all the various electrical testing instruments; and into this room the leads from the dynamos under test are taken. For enabling a dynamo on any part of the holding-down bed to be rapidly connected up with the instrument room, two bare copper rods, extending overhead the whole length of the bed, are fixed to the roof trusses, and insulated by slate. From these are suspended two hanging leads, the lower ends of which can be connected to the terminals of any dynamo under trial. The overhead bars are coupled to leads, which pass through resistances sufficient to give the full load, and then into the instrument room. Nearly all the dynamos now purchased, except those for torpedo boats, are of a capacity of 400 amperes at 80 volts, the latter being the Admiralty standard voltage for all dynamos and electrical fittings; and they are all direct-current and compound-wound. The dynamos are coupled direct to open vertical compound engines, working generally with 100lb. steam pressure at a speed of about 330 revolutions per minute.

The dynamo and engine are required to stand first a continuous trial of six hours' duration with full load. Every half hour the steam pressure, current, and electromotive force are recorded, as are also the temperatures of the testing room, field-magnets, and armature. It is stipulated that one minute after the end of the trial the temperature of any accessible part of the machine must not exceed that of the testing-room by more than 30° Fahr.; and the maximum temperature of the armature at end of trial after stopping must not exceed that of the room by more than 70° Fahr. If these limits are exceeded by more than 10deg. the machine is liable to rejection. These tests for temperature are considered to be of great importance, for if unsatisfactory the dynamo is not likely to remain long efficient. The spare armature which is supplied with each machine is required to undergo a similar test for two hours. The Cardew voltmeter and the Siemens ammeter are the instruments actually used on board ships of the Navy. Very delicate instruments, such as electro dynamometers, are found not to be suitable for use under such circumstances. As additional tests the engines and dynamos are expected to stand without injury the sudden removal of the full load by the breaking of the circuit; and under such circumstances the maximum increase in revolutions or in voltage must not exceed 25 per cent. The dynamos are required also to be compounded so as to give a constant electromotive force of 80 volts when the current is varied from 400 to 10 amperes, the speed being fairly constant during the time; and they are fully tested to ascertain that these conditions are fulfilled.

Engines.—As regards the engines, great importance is attached to their economy in the consumption of steam. The makers are required to state the consumption of water per electrical horse-power per hour, which they will guarantee shall not be exceeded. A fine is incurred for every lb. of water per electrical horse-power per hour in excess of the maximum guaranteed; and if the excess amounts to more than 10lb. per hour the machine is liable to rejection on this account. The water used is carefully measured, and every endeavour is made to avoid losses by leakage of steam, &c. Importance is also rightly attached to the governing arrangements, and it is stipulated that the increase of speed when the load is gradually removed must not exceed 5 per cent.

Resistances.—Before the six hours' trial is started, and immediately after its conclusion, the resistances are observed of the dynamo complete, of the armature, and of the shunt and series-windings of the field-magnets; the resistances are thus obtained both when the circuits are cold and also when they are hot. For this purpose the leads from the terminals of the part whose resistance is required are taken into the testing room, and the resistances are obtained by a bridge made by the Silvertown Company, by a Thomson's marine galvanometer, and by an ordinary scale, for which the light is given by an incandescent lamp behind. The ordinary Daniell cells are used, and a key is introduced, so that one, two, three, or four cells may be switched in at once without altering the leads. The dynamo and engine are further tried when fitted on board ship, and when the whole installation is complete.

(To be continued.)

MAGNETIC VARIATIONS.*

BY WILLIAM ELLIS, F.R.A.S.

In this Paper the author refers to the ordinary variations of the magnetic elements as observed at Greenwich; the annual progressive change; the diurnal variation—large in summer, small in winter, and also larger when sun-spots are numerous and smaller when sun-spots are few; the irregular magnetic disturbances and magnetic storms, and the accompanying earth currents; phenomena which are generally similar at other places.

He then invites attention more particularly to magnetic disturbances. Those at Greenwich may, after a calm period, arise gradually or commence with great suddenness. When sudden, the movement is simultaneous in all elements. The first indication may be a sharp, premonitory, simultaneous movement, followed after a time by general disturbance, or the movement may at once usher in the disturbance. These initial movements are not always great in magnitude, sometimes, indeed, small, but they have a very definite character, and frequently occur nearly instantaneously, as is shown in the character of the photographic traces.

It has been long known that magnetic disturbances occur at the same time over wide areas of the earth's surface, but the accidental comparison in past years of the times of commencement of one or two disturbances at Greenwich with the times at other places has led the author to suppose that the coincidence in time is much closer than had been before supposed, and the definite, and on occasions isolated, character of the initial movement induced him to undertake the collection and comparison of the times of such movements for a number of days at observatories geographically widely separated.

The times of such movements cannot be caught by eye observation without continuous watching of the magnets, so that the photographic registers have to be relied upon, which is better, excepting that the scale of time is necessarily contracted; but, though in individual measures there might be variations, it was conceived that (supposing no systematic error to exist) the mean of a number of comparisons should give a good result. Seventeen days, occurring in the years 1882 to 1889, were selected for comparison, the observatories being those of Toronto, Greenwich, Pawlowsk, Mauritius, Bombay, Batavia, Zi-ka-wei, and Melbourne, and, for a less number of days, Cape Horn (as obtained from the Mission Scientifique du Cap Horn, 1882-83). It was desired to have times for Pola, but it was found that photographic registers during great part of the period did not exist. The variation in time at each place from the mean of times for all places is given for each day. The mean deviation at the different places varies from +2·4 minutes to −2·9 minutes, the agreement between four of the places—Greenwich, Pawlowsk, Mauritius, and Bombay—being very much closer, the mean values of deviation for Greenwich, Pawlowsk, and Bombay differing, indeed, by only 0·1 minute, equivalent to 6 seconds.

The question arises, Are the differences real, or due (considering the contracted time scale) to accidental error? If the magnetic impulse is really simultaneous over the whole earth, it is a striking

* Abstract of a Paper "On the Simultaneity of Magnetic Variations at Different Places on Occasions of Magnetic Disturbance, and on the relation between Magnetic and Earth Current Phenomena," recently read before the Royal Society.

Digitized by Google

physical fact, and if not entirely so, the circumstance is no less interesting; but greater attention to accuracy of time scale, or a more extended scale, may be necessary before the point in question can be definitely settled.

A table is added, showing the character of the magnetic movement at the several observatories, from which it appears that at any one place the movements on different days were in most cases similar, though different at different places, indicating on these occasions the occurrence usually of one general type of disturbance.

Reference is made to the question of earth currents. A comparison for 31 days, between 1880 and 1891, of cases of sudden magnetic movement and earth current at Greenwich, shows the earth current to precede the magnetic movement by 0·14 minute, equivalent to 8 seconds. The question of the relation between magnetic movements and earth currents is discussed.

The desirability of being able temporarily to obtain, when occasion requires, a more extended time scale for all magnetical and meteorological phenomena is pointed out.

The general result is that in the definite magnetic movements preceding disturbance the magnets at any one place are simultaneously affected; also that in places widely different in geographical position the times are simultaneous, or nearly so, a small constant difference existing at some places which may be real or may be accidental, but the character of which it seems desirable to determine. It is shown also that at Greenwich definite magnetic movements are accompanied by earth current movements which are simultaneous, but that neither magnetic irregularities nor ordinary magnetic variations seem to admit of explanation on the supposition of being produced by the direct action of earth currents.

NUREMBERG CARBONS.

The French Vice-Consul at Nuremberg, M. Léon Duplessis, has recently made a lengthy report on the electric carbon industry of that town, from which we take the following extracts:—

"The manufacture of electric light carbons occupies six large factories, belonging respectively to C. Conradty, Ch. Shmelzer, Carl Braun, J. G. Meier, Emile Mahla, and Jules Fuchs. To these may perhaps be added a seventh, namely, that of Dr. Albert Lessing, though the latter does not produce carbons for electric lighting but only battery carbons.

"The raw material employed in this manufacture is 'retort graphite.' As far as the Vice-Consul was able to discover, this material only is used when homogeneous carbons are required; but when cored carbons are to be made a softer substance is added. Before they are ready for use homogeneous carbons pass through twelve, and cored carbons through sixteen different processes. The first operation is to break the graphite into small nuts. For this purpose a three-stamp mill is used. The stamps in falling crush the graphite placed over movable steel gratings that allow the broken material to pass between their bars. These bars are placed nearer to one another, or further apart, according to the size of the pieces required. Having passed this grating the pieces are collected by hand and passed through a sieve. The coarse particles are submitted to a vertical crushing, and the fine are passed on to a rolling mill. The vertical crushing is intended to reduce the pieces of graphite to about the size of semolina grains. The graphite thus treated is directed a second time into a sifting machine. Then follows more rolling. The sixth operation is to damp and mix the graphite obtained from the rolling mill, as well as the powder gathered in the sifting machines, with a binding substance. The mass delivered from this machine being too soft, it is necessary to render it plastic and capable of taking a shape, and with this object it is consigned to a sort of puddling machine which produces a species of paste. This paste is pressed through a machine fitted with dies. These produce coarse rods or other pencils, according to the diameter of the cylinders. The rods so prepared are introduced into steel hydraulic cylinders and submitted to a pressure of about 25 atmospheres. Some of these hydraulic presses—the construction of which the Nuremberg manufacturers have only attained by successive steps—can deliver 500 metres of carbon per hour or from 2,000 to 3,000 arc light carbons of average size. All these operations terminated, the carbons obtained are baked in a blast furnace where the temperature occasionally attains as much as 2,000deg. centigrade. When homogeneous carbons are withdrawn from the furnace they have only to be passed on to an automatic cutting machine. This machine is in direct communication with a ventilator which draws off the powdered carbon produced in cutting.

"The construction of machines employed in the manufacture of electric light carbons is also a Nuremberg specialité, and the house of Justus-Christian Braun has a monopoly of the business, and supplies machines in Europe and America. The cost of an outfit for a factory is put at 20·435 marks, irrespective of packing, transport, and Customs charges."

The following table is given as representing the average ruling prices of electric carbons at Nuremberg:—

Mm.	Per metre.		Mm.	Per metre.	
	Cored.	Homogeneous.		Cored.	Homogeneous.
	Fr.	Fr.		Fr.	Fr.
5	—	0·50	15	1·90	1·78

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 3, 1892.

The Niagara Falls Power Plant.—The Niagara Falls power plant is rapidly assuming definite shape. The tunnel on the American side which it was first intended to build through the solid rock without other walls than the natural stone, has, according to later plans, been lined with brick. The wall being 16 inches thick, the space between the brick work and rock has been filled with broken stone and cement, the original supporting timbers being left in place. This lining has reduced the capacity of the tunnel from 120,000 H.P. as originally estimated to about 100,000. The finished height is 21 feet and the width 19 feet with a cross sectional area of 365 square feet for its entire length of 7,600 feet. The grade is about 1 in 150 and there is a difference of level of 200 feet in the surface of the water in the canal and the tunnel discharge, about 140 feet of which will be available as a working head at the turbines. The manufacturer who locates at Niagara will have the opportunity of choosing between two methods of obtaining power; he may either put in his own wheel pit, penstock and wheels, and discharge the water into the tunnel as a tailrace, or he may equip his factory with electric motors and obtain his current from the immense power house which the Niagara Falls Power Company will build and operate. For the smaller manufacturer the latter method will probably prove to be the most economical arrangement, and it is probable that considerable demand will be made for current to be used in this way. To meet this demand the Company is putting in a station at which two turbines of 5,000 H.P. each will be installed at the outset. These turbines are built in this country from designs furnished by Faesch and Picard, of Geneva. The vertical shafts of these wheels will carry at their tops the armatures of two multipolar dynamos. The weight of the bearings is supported by the pressure of the water under the running head. This station is so designed that it can be extended to 50,000 H.P. ultimately. The wheel pit is now being excavated and is 140 feet in length and 18 feet in width.

The Chicago Exhibition.—The rapidity with which the constructors are pushing the World's Fair Buildings to completion may be judged from the fact that over 100,000 men are now employed within the grounds. Very little additional information is to be obtained regarding the department of electricity; it may be said, however, that the department is soon to announce the allotment of space to the different American exhibitors, and that it will be divided in accordance with the willingness and the ability of the intending exhibitors to make displays of the very best character. The incandescent lighting of the different buildings is being carried out in accordance with the original plans, except that they have been very much enlarged to meet the unexpected demands for

Digitized by Google

interior illumination. The original designs contemplated the use of 100,000 incandescent lamps besides a large number of arc lamps; but present indications are that at least 250,000 and perhaps 300,000 will be called for. As now planned the manufacturers' building will have 28,000 incandescent lamps; the art gallery, 12,600; the annexes, 18,000; the administration building, 15,000; machinery hall, 7,600; and the basins, 6,100; the agricultural building, 5,000; Government building, 5,000; mining building, 4,800; transportation building, 3,200; woman's building, 3,200; choral building, 2,000; offices construction department, 1,800; fisheries' building, 1,000; Illinois building, 2,500; Pennsylvania building, 800; California building, 600; German building, 500; Japanese, 500; French, 500; other buildings, 25,000. Among the other buildings an average of about 200 each is assigned and for the midway plaisance, 15,000. This allotment does not include the electricity building, where 100,000 will be placed. The designs for the arc lamp posts are completed and are waiting for approval. Where single arc lamps are to be used the lamp will be suspended from the middle of a golden lyre, from which is raised a canopy of galvanised iron. Where groups of arc lamps are necessary a similar design will be used but having a triangular top in which three arc lamps will be suspended.

CORRESPONDENCE.

THE MAGNETIC CURVE TRACER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The remarks made in your Editorial Notes of September 9th suggest to me the desirability of adding a few words to what was said in Section A, regarding the use of the magnetic curve tracer to exhibit high-speed cycles of magnetisation. You refer to me as having "repudiated any mechanical inertia," but it should be understood that I was then speaking of certain phenomena which presented themselves when the cycle of magnetisation was gone through so slowly that no effects of mechanical inertia could have been sensible. At high-speeds the effects of inertia are, of course, felt, and appropriate means must be taken to avoid them. The case is similar to the familiar one of a steam-engine indicator. To adapt the indicator to high-speed working, we reduce to the utmost the mass of the moving parts and use a stiff spring. To adapt the magnetic curve tracer to high speeds we use a light mirror and tighten or shorten the stretched wires. In both cases we have to be content with a comparatively small diagram as a result of the stiffer spring or the tighter wire. In both cases ripples due to the free vibration of the working parts are liable to be superposed on the main cycle of movement; and to keep these within bounds it is essential that the period of free vibration should be many times less than the period of the main cycle.

In the instrument which I showed at Edinburgh, there was no difficulty in getting a satisfactory undisturbed diagram at any speed up to 20 cycles per second, or even more. But on the occasion of the lecture the weights that kept the wires tight were reduced for the sake of getting a big diagram projected on the screen to values which were just sufficient to allow a frequency of 10 or 12 cycles per second to be reached before the disturbing effects of inertia began to be felt. Unluckily, the revolving commutator, which was used to produce periodic reversals of the magnetising current, misbehaved itself towards the end of the lecture, the motor ran away, the speed became too high for the lightly loaded wires, and the curve was distorted—an effect mainly, if not wholly, due to mechanical inertia. Still more unluckily, what Lord Rosebery has just been calling the "sleepless editorial eye" transferred its impressions of this embarrassing moment to the editorial note-book in the sketch, which appeared in your British Association Notes of August 12th.

In reply to Prof. Perry's question, I named 20 cycles per second as a limit of speed within which the instrument exhibited had given a perfectly satisfactory B-H curve. To secure a good diagram at this speed the wires have to be somewhat tightly stretched, but not so tightly as to prevent the diagram from being fairly large. No doubt, with shorter and tighter wires and a lighter mirror, still higher speeds are practicable; but experiments in this direction have still to be made. For very high speeds I think it may be found best to use two mirrors, each having one component of motion, with successive reflection of the light from both.

In the chief use of the instrument, namely, the magnetic testing of samples of iron or steel, the cycle is gone through at so comparatively slow a rate that the mechanical inertia of the working parts is absolutely without influence. Using a revolving commutator of the type employed in my lecture, which gives gradual variation of the current from positive to negative and back, or from zero to any value, the observer will turn this slowly enough to follow with a pencil the movement of the spot of light over the curve. A much higher speed than is possible in this operation would still be so slow as to escape all disturbance from mechanical inertia.

When the samples are solid bars, the observer will find that he must go slowly, not because of mechanical inertia at all, but because of the sluggishness which the iron exhibits in taking up the full amount of magnetism proper to each value of the magnetising current. When the samples consist of thin sheet or of wire, this sluggishness is not found, and he may then go as fast as he is able to follow the movement of the spot.—Yours, &c., J. A. EWING.

Connel Ferry, Argyllshire,
September 12, 1892.

MAGNETIC VISCOSITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The Messrs. Hopkinson's experiments are of great interest, and confirm in many respects the conclusions arrived at by Mr. Vignoles and myself more than a year ago, namely, that there is no magnetic viscosity making anything like 10 per cent. difference between the work done in carrying a piece of soft iron through a magnetic cycle in two or three seconds and in one hundredth of a second. It is true that the slow-cycle observations in Messrs. Hopkinson's Figs. 2 and 5 lie within the quick-cycle curve at those parts of the cycle taken just after the iron has passed through its nearly unstable condition; but in a Paper read to the Old Students' Association (*Electrician*, May 22, 1891, page 77) Mr. Vignoles drew attention to this effect, and stated that we had discovered the cause of the discrepancy, which we can assure Messrs. Hopkinson is not due "to something peculiar to experiments with the ballistic galvanometer," but is an effect of the very viscoscity of which they say "there is no sign." Had the slow cycle been obtained by the method described by Mr. Vignoles, Messrs. Hopkinson would have found it in almost absolute agreement with the quick-cycle curve. These points are fully dealt with in our forthcoming articles.

May I suggest to Dr. Hopkinson that he should add to the obligations under which he has already laid us, by publishing complete data of the experiments by which his results were arrived at, as without such information much valuable experimental work is rendered comparatively useless in future research.—Yours, &c. SYDNEY EVERSHED.

Woodfield Works, W., Sept., 13th, 1892.

[In Mr. Evershed's first article of the series on "The Magnetic Circuit of Transformers, Closed versus Open," *Electrician*, Vol. XXVI., p. 478, speaking of Prof. Ewing's model and the Weber-Maxwell theory of molecular magnets, he wrote, "It certainly seems well-nigh incredible that molecular magnets should be incapable of executing forced vibrations at what must, from a molecular point of view, be a very leisurely pace." In § 7, alluding to viscous hysteresis, he wrote, "As to a lag comparable with such short times as one-tenth to one-hundredth of a second, there is no evidence whatever of its existence and never will be until eddy currents are entirely eliminated from experimental results."—Ed. *E.*]

THE USE OF BI-METALLIC CONDUCTORS ON ARMATURES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of September 9, 1892, you mention in your Notes "The Reignier and Parrot Dynamo." I wish to point out that MM. Reignier and Parrot are by no means the first in the field. My patents No. 126^{89} and 1068^{90}, and also that of Mr. R. E. B. Crompton, No. 5750^{90}, have entirely covered the ground as far as "bi-metallic" conductors on armatures are concerned in England. A single glance will show the superiority of the "Crompton" machine in the mechanical construction of the armature.

With regard to eddy currents in the conductors, the type used by Mr. Crompton and also by MM. Reignier and Parrot (an iron strip between two copper strips or simply a copper-plated iron strip) is singularly defective, being in fact the worst form of bi-metallic conductor. In all cases the iron should encase the copper and not *vice versa*, otherwise eddy currents will be set up along the copper on the sides of the conductor, as shown by the direction of the arrows in Fig. 1. For this reason I have entirely abandoned copper-plated iron conductors.

The best form of bi-metallic conductor is shown in Fig. 2 in section. This form reduces the magnetic resistance of the actual air gap by about 20 per cent., and is free from eddy currents. A third form consists of a copper wire wound over with iron wire or strip. This last is more suitable for small or for high tension machines.

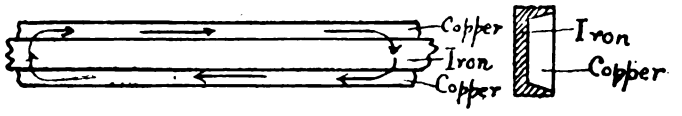

FIG. 1.

FIG. 2.

The possible output of any machine is limited by sparking only where no temperature limit is given, within reasonable limits. The sparking limit of a machine, the armature of which is wound with bi-metallic conductor, can be found from the following modification of Mr. Esson's formula which I have found to be correct in practice.

$$v = \frac{288\, I\,(l + \frac{d}{\mu})}{\phi}$$

where v is equal to the number of conductors on the armature multiplied by the current in ampères flowing in each, I is equal to the average induction per square centimetre, μ = the average permeability of the conductor, l = length of the actual air-gap expressed in centimetres, d = depth of the iron conductor, and ϕ = the angle embraced by each pole-piece.

From what I can gather, from the particulars given in last week's issue, and from "Industries" it appears that the "Reignier-Parrot" machine will reach the sparking limit at less than half load with ordinary clearance for the armature. About 1·1cm. clearance on each side would have to be allowed to prevent sparking. The number of ampère turns on the field-magnets to overcome the magnetic resistance of the gap space alone would be about 35,000. Any well designed four-pole machine would give the same output, if sufficient ventilation could be provided. The use of bi-metallic or iron conductor will not reduce the magnetic resistance of the gap-space (including conductors) without reducing the output of the machine. By the proper use of bi-metallic conductors, any machine can be worked up to its sparking limit without overheating. Since the possible output of any machine varies inversely as the angle embraced by the pole-pieces, it is evident that the possible output of any machine is doubled without increasing the total armature induction by using twice the number of poles of half the angular width. This fact is of no use in ordinary machines on account of the temperature limit, but with bi-metallic conductor wound armatures it can be made full use of. Magnetic leakage, spreading of the lines of force and cost of manufacture alone form the limit to the number of poles, and consequently of the output of the machine. Magnetic leakage and spreading of the lines of force over too great an angle can be compensated for by making the armature somewhat larger in diameter. By using a modified form of the "Mordey Alternator" magnet eight to twelve poles can be used on medium-sized machines without increased cost.

The following are a few particulars of one of my small four-pole motors, which runs without sparking or overheating:—Size, 15in. by 8½in. by 8½in.; weight, 71lbs.; speed, 1,800; potential difference at terminals, 35 volts; maximum current for continuous running without sparking, 35 ampères; electrical power absorbed, 1,225 watts; power on shaft, 1,000 watts or 1·34 H.P.; commercial efficiency, 82 per cent.; number of watts output per kilo. of dead weight, 31. The field magnets are of cast iron of doubtful quality. By substituting wrought iron cores the weight can be reduced to 55, which brings the number of watts per kilo. up to 40. The total number of ampère turns on the field magnets is 4,000.

—Yours, &c.,

G. B. LÜCKHOFF.

Croydon, September, 1892.

FIRE RISKS AND RULES IN AMERICA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A leading article under the above heading in your last issue refers to a communication which I have sent to an American journal on this subject. As your article is likely to create an erroneous impression of what I have stated, I feel called upon to endeavour to justify my statements, and also, with due deference and regret, to express my disagreement with most of the remarks and conclusions arrived at in your leader.

On the 23rd July last the *Electrical World* writes: "Fire underwriters are greatly disturbed by the increased fire losses said to be due to electricity. . . . . It is contemplated to increase the rates where electricity is used." And the journal solicited articles on this subject. I replied to this invitation by describing the state of affairs in England, asserting the fact, which I have on the best of authorities and which I firmly believe to be indisputable, that in England no such alarm is felt by the insurance companies, and that premiums are not raised where electricity is used, nor has a single fire occurred which could be traced to electricity as its cause. I endeavoured to prove that this very marked difference existing in the two countries is largely due to intelligent inspection; that rules alone are useless without the personal inspection by which we have benefited to so considerable an extent in England not only as contractors, but also as manufacturers of cables and fittings, and I concluded my remarks by advising the American insurance companies to establish an authority like Mr. Musgrave Heaphy.

To such advice you evidently take exception, and your own advice to the Americans may be construed from your remarks to be somewhat as follows:—"Do not imitate such rules and such inspection. The former are vague, and the latter is highly unpopular and has caused much annoyance. Allow matters to right themselves. We can discern many signs that you are bettering yourselves, thus you are taking the best possible course."

This is a direct contradiction to what I have advised. May I be permitted to ask what are the reasons which lead you to believe that matters in America seem to be taking the best possible course? Your article enumerates several reasons, chief among which are the following:—"The insurance companies are beginning to bestir themselves in the United States, and a meeting of electrical insurance experts has been held." This is no doubt a sign that something will be done, but it is also a sign that things are pretty bad in the States. "You understand that fire risks are decreasing. In 1889 there were 119 fires due to electrical causes, in 1890 there were only 75." This decrease is, according to our notions, scarcely satisfactory, and the less so in view of the announcement in July, 1892, that "fire underwriters are greatly disturbed by the increased fire losses." The third reason that you give to prove that matters seem to be taking the best

Digitized by Google

possible course is to my mind still less convincing than the other. "You have been glancing through the advertisements in the *Electrical World*, and its Patent Record, and find that they teem with descriptions of improved contacts, switches, safety devices, wire claiming high insulating properties," &c.

As a general rule, I decline to accept the descriptions given in high-flown (especially American) advertisements as a proof of good quality. May I ask you whether you have seen or tested any of these advertised wires, switches, or insulators? I have, and in making the statements contained in my letter, I am not making them as merely derived from the perusal of newspapers, but am speaking from actual experience. I have found (of course you may take this as an individual opinion only) that the porcelain made in America is inferior in insulating properties to the china made in the English potteries—surface leakage owing to this cause, to the indiscriminate method of fixing screws, to covering them with substances like shellac, and to exposing them to the atmosphere without any covering, is of common occurrence in American electric light fittings. I also find an improper use of such hygroscopic substances as vulcanised fibre in cut-outs, holders, and switches. I have found no standards as to breaking distances, and divisions between poles, &c., and as regards the insulation of cables and wires, the very multiplicity of them proves that our transatlantic friends are very much at sea on this question, and that a little wholesome—even if "unpopular"—inspection might prove a boon to the contractor and manufacturer.

These questions and many more relating to articles used in wiring houses have received constant and careful attention in England with beneficial results, and let me ask the electrical trade, from the largest manufacturer to the smallest contractor, whom have we to thank for these results? and I feel confident that the majority will point to that inspector and to his interpretation of that code of rules which you have characterised as "highly unpopular, and causing so much annoyance," and which you wish to condemn on account of their "vagueness and need for separate interpretation," as if, during the past stage of electrical manufacturing, and even at the present moment, any more definite rules could possibly be devised without being subject to almost weekly alteration. What was considered the best yesterday has to be condemned to-day. Inventions and improvements are being made almost daily, and this "vagueness" of rules will doubtless disappear as soon as electrical manufacturing has arrived anywhere near perfection, but this "separate interpretation," this close inspection have been the very best thing possible for us as manufacturers and contractors. That the inspection has caused some annoyance and been unpopular cannot be denied, but its unpopularity is becoming less and less marked as the purport and beneficial influence of such inspection is more and more understood and appreciated.

American electrical engineers might do worse than subject themselves to such "annoyance," or to work under such "unpopular" interpretation of rules.—Yours, &c.,

London, Sept. 12, 1892. G. Binswanger.

SUBMARINE TELEGRAPH RELAYS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Referring to your Editorial comment in *The Electrician* of August 26th, on the performance of M. Willot's relay between Paris and Algiers, four words per minute, it may interest you to know that nearly four years ago (September 16, 1888) twenty words per minute were received by sounder at St. Pierre (Miquelon) from Duxbury, Mass., over the Anglo-American Cable; distance, 878 miles; resistance, 8,300 ohms; capacity, 256 m.f. In this test a Brown and Allen relay was used as receiver, and a system of transmission of my own invention was used at Duxbury.

I do not know the character of the Paris-Algiers circuit, but from the map the distance appears to be about the same as from Duxbury to St. Pierre. I expect to obtain much better results than the foregoing in a trial soon to be made with my complete system of cable telegraphy.—Yours, &c.,

South Orange, N.J., Sept. 6th. Patrick B. Delany.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Tenders Invited.—Tenders are invited by the Corporation of Southampton for the electric lighting of the Corporation waterworks at Otterbourne, near Shawford. Specification and form of tender may be had and all further particulars obtained upon application to Mr. J. G. W. Aldridge, electrical engineer, at 9, Victoria-street, Westminster, and at 23, High-street, Southampton, after the 15th inst. Tenders must be in by 2 o'clock on the 27th inst. Further particulars are given in our advertisement columns.

Plant for Sale.—Our advertisement columns contain a notification of the sale by private treaty of the lease of the premises lately occupied by Mr. J. Collins at Hove, together with the modern stock of electrical plant. Full particulars may be obtained of Messrs. Ward and Wilding, chartered accountants, Bloomsbury Mansions, Hart-street, London, and 8, North-street, Brighton; or of Messrs. Bullock and Sadler, 33, Queen's-road, Brighton.

Works and Plant for Sale.—The electrical and engineering works at Carntyne, Glasgow, recently occupied by Mr. Rankin Kennedy, are to be sold by public auction at the Faculty Hall, Glasgow, on Wednesday, October 5th, at 2 p.m. Inventories may be seen and all further information obtained on application to Messrs. Dunlop and Murray, C.A., 82, West Regent-street, Glasgow, or to Messrs. Carruthers and Gemmill, writers, 62, Bath-street, Glasgow. Further particulars are given in our advertisement columns.

Berwick.—At the last meeting of the Berwick Urban Sanitary Authority, the Mayor, in answer to inquiries, stated that the matter of lighting the town by electricity was still before the committee appointed to consider the question.

Blackpool.—We are asked to state that as the Corporation have taken over the plant of the Blackpool Electric Tramway Company (Limited), all communications for this department should in future be addressed to the General Manager (Mr. John Hesketh), who is also the borough electrical engineer.

Essex.—At the last meeting of the Shire Hall Committee the subject of lighting the Shire Hall and Clerk of the Peace's office by electricity was under consideration, but owing to the fact that a consulting electrical engineer asked for the exorbitant fee of 20 guineas for going carefully into the question and advising the committee, it was ultimately decided to reject the special committee's recommendation to adopt the light.

Hammersmith.—The Hammersmith Vestry have resolved to apply for a Provisional Order, empowering the Vestry to supply the district with the electric light.

Hayle.—Mr. F. M. Newton, of Taunton, has completed an electric light installation at Copperhouse, a large establishment owned by Messrs. J. and F. Pool, metal perforators and ironmongers, Hayle.

Oldham.—The Oldham Board of Guardians have appointed a committee for the purpose of investigating the best means of lighting the workhouse by electricity.

Western Union Telegraph Company.—This Company announce that they have opened a new office at 40, Mark-lana, E.C., for the reception and delivery of messages for and from all parts of North, Central, and South America, Canada, Bermuda, Bahamas, West Indies, &c.

Fire Protection.—We have received from Messrs. Merryweather and Sons (Limited), of Greenwich-road, a pamphlet giving practical hints on fire protection of towns and buildings. Accompanying the pamphlet are illustrations showing designs of the various engines and other apparatus and specialities manufactured by the firm for fire extinction. The pamphlet is written by Mr. J. Compton Merryweather, M.I.M.E.

Copper.—Messrs. E. le Bas and Co. inform us that the Mint, Birmingham, Limited (Ralph Heaton and Sons), for whom they are the sole London agents, have just completed their hot-rolling mills department for brass and copper sheets and rods. They also make a speciality of high-conductivity copper wire, sheets, rods, and all kinds of tubes. They have also a special department for all kinds of stampings and spun work in copper and brass.

New Branch. — Messrs. Woodhouse and Rawson, United (Limited), have opened a new branch office at 13, Paragon-arcade, Hull.

Removal Notice.—The registered offices of the General Electric Power and Traction Company (Limited), have been removed from New Broad-street House, New Broad-street, to Worcester House, Walbrook, London, E.C.

Appointment.—The Dundee Gas Commissioners have appointed Mr. James Small Borough Electric Lighting Inspector.

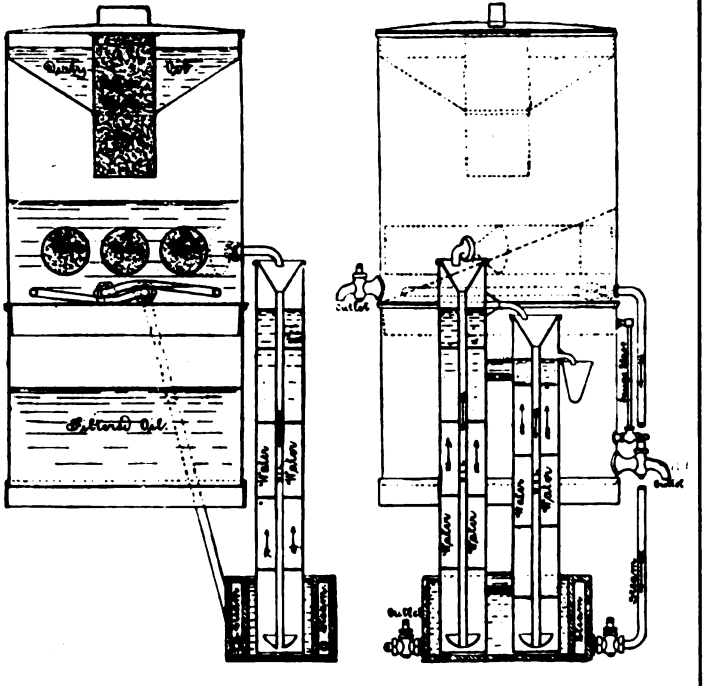
Digitized by Google

Electric Launches.—Messrs. Woodhouse and Rawson, United (Limited), inform us that they have on view at their show-rooms at Cannon-street, E.C., a working model of the electric launch Glowworm recently designed and built by them for Mr. Andrew Pears.

Wiring in the City.—We are informed that the contracts for the wiring and fitting of Leadenhall House, New Zealand Chambers, and Billiter-avenue Buildings, comprising over 1,500 16 c.p. lights have been signed this week by Messrs. H. Binko and Co., of 34, Leadenhall-street.

W. T. Henley's Telegraph Works Company (Limited).—In reference to the paragraph which appeared in our last issue concerning the winding-up of Henley's Telegraph and Electric Construction Company (Limited), we are asked to state that this winding-up has no reference whatever to W. T. Henley's Telegraph Works Company (Limited).

Turner Patent Oil Filter.—We have received from the Turner Patent Oil Filter Company, of Preston, Lancashire, particulars of their patent filter, for which they claim many advantages over other filters in the market; included in these claims is one that the "Turner" filter is alone capable of effectually cleaning spent and impure oils, and removing all traces of water therefrom. Our illustration gives a view of the No. 1 size filter, for which printed



working instructions are issued by the Company, and which are simple and easily acquired. By the use of these filters water, grit, dirt, and all metal particles are removed, and the spent oils can be used over and over again. The filters are made in several sizes, to filter from four to 100 gallons per week. They have been adopted by the Post Office Telegraphs Department, and are in use at a number of electrical engineering works in this country and abroad.

Messrs. Dorman and Smith.—We have received the newly-issued illustrated price list of this firm giving full particulars of their manufactures, including holders, switches, regulators, switch-boards, cut-outs, wall sockets, ceiling roses, pendants, brackets of all kinds, and a variety of ships' and general fittings for the electric light. The list contains nearly 100 illustrations of goods actually manufactured by the firm. It is satisfactory to note that Messrs. Dorman and Smith's new large works at Salford are now in full work.

Edison and Swan United Electric Light Company.—We hear on good authority that the reports which are being circulated as to the strike at the works of this Company are much exaggerated. No interference with the general business of the firm is anticipated.

Poole and White (Limited).—On the application of Mr. L. Hervé, Mr. Justice Bruce (the vacation judge) made an order for the compulsory winding-up of this Company on Wednesday last.

Electrical Engineering Corporation, Limited (in liquidation).—We learn from Mr. F. W. Pixley, the receiver and manager of the above Corporation, that as the realisations of the assets will not pay 20s. in the pound to the debenture-holders the unsecured creditors will receive nothing.

Siam Electric Light Company.—We understand that the affairs of this Company have been satisfactorily settled, the Treasury having advanced £20,000 for the payment of creditors. Upon certain conditions the Brush Electrical Engineering Company undertake to put the machinery in order, after which the concern will either be sold by auction or the Government will take it over by private arrangement.

Electrical Cookery.—Not to be behindhand in matters electrical, the chief citizens of Ottawa were recently invited to a banquet in which the cooking was entirely done by electricity. Amongst the company was the Mayor of Ottawa. The electrical caterer was Mr. T. Ahearn, of Messrs. Ahearn and Soper, of Ottawa. The entire *menu*, including the bread, was cooked and prepared electrically, and the banquet was a phenomenal success.

Sanitas.—Owing to the cholera scare the Sanitas Company have had a tremendous demand for their manufactures, which has necessitated their works being kept going night and day for some time past. Many of these orders are from large engineering establishments throughout the country who have found the Sanitas specialities most valuable disinfectants.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by Mr. J. C. Chapman, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

August 15, 1892.

14,700. J. D. Morrison. London. A method of making and using binomic baths to mechanico-chemically and hydro-electrically exalt the health of the people.

14,719. T. Floyd. London. Improvements in and relating to electrical storage batteries.

14,720. A. J. Jarman. London. Improvements in and relating to electrical storage batteries.

14,738. C. Coerper. London. Improvements relating to electric arc lamps.

August 16, 1892.

14,769. W. P. Thompson. Liverpool. Improvements in brushes for dynamos. (H. H. Cherry, S. D. Younglove, L. House, and W. C. Raymond, United States.)

14,799. A. H. Vesey. London. Improved electrical switch.

14,805. H. R. Low. Twickenham. Improvements in electric arc lamps.

14,806. H. R. Low. Twickenham. Improvements in motors for alternating currents.

14,813. F. P. Usher. London. Improvements in electric battery plates.

14,814. E. P. Usher. London. Improvements in storage batteries.

14,815. E. P. Usher. London. Improvements in storage batteries.

14,816. E. P. Usher. London. Improvements in electric battery plates.

14,819. H. Wyatt. London. Improvements in and relating to electric arc lamps.

14,822. H. H. Lake. London. Improvements in incandescent electric lamps. (Eugene McOuat, United States.)

August 17, 1892.

14,859. H. L. T. Lyon. London. Improvements in telephonic connections.

14,886. A. Wright. London. Improvements in cut-out switches and cases for containing and protecting the same.

August 18, 1892.

14,928. F. H. Medhurst. London. A new or improved non-sparking switch.

14,947. A. J. Jarman. London. Improvements in the plates or electrodes of electric storage batteries.

August 19, 1892.

14,974. W. T. Goolden and S. Evershed. London. Improvements in electric measuring instruments.

15,002. J. Hines. Liverpool. Improvements in telephony or means for transmitting telephonic signals through long distances.

August 20, 1892.

15,035. J. H. Rider. Halifax. Improvements in automatic switches.

15,038. A. E. Vidal and G. Herveen. London. Improvements in electrical winding mechanism for clock movements.

15,057. J. Brockie. London. Improvements in electric arc lamps.

15,059. H. C. Gover. London. Improvements in portable electric incandescent lamps, and in battery cells and fittings therefor; also partly applicable to electric batteries generally.

15,066. C. E. Webber and G. H. Nisbett. London. Improvements in electrical cut-outs for high-tension currents.

August 22, 1892.

15,113. J. P. Roubertie, V. Laperye, and U. Grenier. London. Manufacture of caustic soda and potash and hydrochloric acid by electrolytic treatment of chloride of sodium and chloride of potassium, and apparatus for this purpose.

15,120. H. W. Headland. London. Improvements in or applicable to electrical accumulators or secondary or storage batteries.

August 23, 1892.

15,167. B. J. B. Mills. London. Electrically illuminated signs or devices, partly applicable to other purposes. (A. D. Page and E. J. McAllister, United States.)

15,179. J. R. Bailey, L. C. Lincoln, and The Woonsocket Edge Tool Company. London. Improvements in arm rests for telephone operators.

15,187. A. E. Le Rossignol. London. Improvements in working and regulating glow lamps and in apparatus therefor.

15,188. E. F. H. H. Lauckert. London. Improvements in electric arc lamps.

15,194. E. L. Mayer and A. C. Jameson. London. A new or improved telephone transmitter.

15,197. H. M. E. Andreoli. London. Improvements in electrolytic apparatus.

August 24, 1892.

15,238. A. R. Bennett. London. Improvements relating to telephonic switching apparatus.

15,240. Hayward Tyler and Co., and C. P. Hammond. London. Improvements in joining or junction boxes for electric cables or wires.

August 25, 1892.

15,296. H. C. Bull and J. Ramage. Liverpool. Improvements in and appertaining to electrical accumulators.

15,298. F. Bryan. London. Improvements in holders for incandescent electric lamps.

15,315. R. W. H. Newington and E. Priddle. London. Improvements in electrical batteries and their application for curative and remedial purposes.

15,318. H. H. Leigh. London. Improvements in electrical transformers. (G. M. Apollonj, Italy.)

15,319. D. Federman. London. Improvements in and relating to electric batteries.

August 26, 1892.

15,329. E. Horton. Birmingham. Improvements in gas, electric light, and lamp fittings.

15,356. H. C. Bull. Liverpool. An improved electro-chemical process for treating iron pyrites thereby recovering everything valuable contained therein and avoiding all noxious fumes.

15,372. W. Boggett. London. Improvements in the method and means of obtaining electricity.

15,376. F. O. Clapcott. London. An improved system of automatic telegraphy.

15,377. R. L. Hattersley. London. Improvements in switches for electric lighting.

August 27, 1892.

15,405. H. Oppenheimer. London. Improvements in and connected with telephone switches.

15,426. J. W. Savage. London. Manufacture of an elastic compound for electrical insulation and other purposes.

15,437. W. E. Gray and W. A. Price. London. An improved method of making electrical contacts between parts of electrical apparatus.

15,441. A. J. Howes. London. Improvements in arc electric lamps.

August 29, 1892.

15,477. A. F. W. Kreinsen. Manchester. Improvements in the means for, and method, of melting metals and other materials by electricity.

15,492. H. H Lake. London. Improvements relating to the lubrication of parts of machinery with the aid of electricity. (J. F. A. Höper and A. Jacobsen, Germany.)

15,501. J. Domecq-Cazoux. London. Improvements in means for lighting oil lamps by electricity.

August 30, 1892.

15,552. W. J. Eastman. London. Improvements in and relating to electric cigar lighting lamps.

15,591. J. C. Wüst. London. Improvements in electric arc lamps.

August 31, 1892.

15,649. J. Stoerk. London. Apparatus for continuous decomposition of alkaline chlorides by electrolytic fusion.

16,650. G. G. di Giovanni. London. Electric apparatus for illuminating the sights of firearms at night.

September 1, 1892.

15,665. J. Dick and W. Scott. A method of eliminating the cross magnetism in the armatures of continuous current dynamo-electric generators and motors.

15,671. D. Balmford. Bradford. Medicated electricity or special use and application of electricity for medical purposes.

15,689. C. R. J. Willot. London. Improvements in relays for electric telegraphs.

15,690. B. and A. Kochs. London. Improvements in overhead trolley for electric railways.

15,691. C. Drill. London. Improvements in electric air ships.

September 2, 1892.

15,746. H. P. Fils. London. Improved globe for reflecting arc lights.

15,767. W. Moscrop. London. Improvements in gas outlet valves or plugs for electric battery cells or other like vessels.

15,790. H. C. Gover. London. An electric lantern.

15,793. C. G. P. de Laval. London. Method of smelting or overheating iron or other metals by means of electricity. (Date applied for under Patents Act, 1883, section 103, March 8, 1892, being date of application in Sweden.)

15,795. S. F. Walker. London. An improved system of electrical distribution.

15,799. E. Nunan and J. W. Nelson. London. An improvement in galvanic batteries.

September 3, 1892.

15,813. A. M. Thompson. Crewe. Improvements in the formation of junctions for electric mains.

COMPANIES' MEETINGS & REPORTS.

Direct Spanish Telegraph Company (Limited).

The following report of the Directors for the half-year ended 30th June last will be presented at the general meeting of shareholders, to be held on Tuesday next, the 20th inst., at Winchester House, Old Broad-street, E.C., at 2 p.m.:—

The accounts for the half-year ended 30th June, 1892, show, after providing for debenture interest, a balance to the credit of profit and loss of £5,438. 2s. 7d. The traffic receipts show a decrease of £45. 8s., as compared with those of the corresponding period of 1891. They may, however, be considered satisfactory, as in the half-year of 1891, with which they are compared, the present reduced tariff had not come into force. The working expenses are £170. 7s. 7d. in excess of those for the corresponding period of last year.

The Company's cables, and the land-lines in connection with them, have continued in good working order throughout the half-year.

After putting the usual sum of £2,500 to the reserve fund, the balance of profit and loss amounts to £2,938. 2s. 7d. Out of this amount the Directors recommend the payment of the dividend at the rate of 10 % per annum on the preference shares, and a dividend at the rate of 4 % per annum (free of income-tax) on the ordinary shares. There will then remain a balance of £441. 3s. 0d., which will be transferred to the reserve fund in part repayment of the sum of £2,376. 12s. 4d., taken from that fund towards the repairs of the Falmouth-Bilbao Cable in November, 1891. The reserve fund will then amount to £29,827. 2s. 10d. The dividend warrants will be issued on the 1st of October, 1892.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "The Electrician" Electrical Trades' Directory and Handbook, 1892, pages 308-322, *&c., &c.*

ARMSTRONG'S ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company was dissolved under Clause 7 (4) of the Companies Act, 1880 (43 Vict. ch. 19), by notice in the *London Gazette*, dated August 16, 1892. The Company was registered on November 2nd, 1887, with a capital of £20,000 in £1 shares. Repeated notices were sent to the Company signifying that noncompliance with the regulations would result in the striking off of the Company from the register ; and as a result, the usual proceedings have been taken.

CALIFORNIA GAS, WATER, AND ELECTRIC LIGHT COMPANY SYNDICATE (LIMITED).—The statutory return of this Company, made up to April 15, 1892, was filed on August 30, 1892. The nominal capital is £2,000, in £1 shares. Of these, 1,475 have been taken up, the full amount called, and all calls (£1,475) paid. Registered office, 20, Bucklersbury, E.C.

CITY NOTES, &c.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED). — The Directors of this Company have resolved to recommend, subject to audit, a dividend at the rate of 6 per cent. per annum on the preference and ordinary shares of the Company for the six months ended 30th June, 1892, making, with the interim dividend paid last February, 6 per cent. for the year. The transfer books of the Company will be closed from the 19th to 28th September, both inclusive. The meeting of the shareholders will take place on Tuesday, the 27th September, at Winchester House, E.C.

CALLS DUE.—*24th Sept.*: National Telephone Company (Limited), £1 10s. per share on 90,950 £5 per cent. non-cumulative 3rd preference shares of £5 each.

Digitized by Google

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended Sept. 11th were £768, as against £665 for the corresponding period of last year, being an increase of £103. The total receipts for half-year amount to £8,458, against £7,734 in the corresponding period of 1891, being an increase of £724.

COMMERCIAL CABLE COMPANY.—A quarterly dividend at the rate of 7 per cent. per annum has been declared by the Directors of this Company, payable 1st October. The transfer books will be closed on the 20th inst, reopening on the 3rd prox.

NEW TELEPHONE COMPANY (LIMITED).—Share certificates in this Company can now be obtained at the Company's offices, 110, Cannon-street, E.C., in exchange for bankers' receipts.

STOCK EXCHANGE SETTLEMENTS.—The Stock Exchange Committee have appointed special settling days in the following stocks:—Monday, September 19th, Australian Gold Recovery Company's shares, 52,501 to 160,000; Metropolitan Electric Supply Company's £50,000 Five per Cent. Debentures; and have ordered all the above securities to be quoted in the official list.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—A dividend at the rate of 7 per cent. per annum on the preference shares for the six months ended 30th June last will be paid on the 1st October.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Sept. 9, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,753.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 749.—Vol. XXIX. FRIDAY, SEPTEMBER 23, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

In his presidential address to the Iron and Steel Institute on Tuesday last, Sir Frederick Abel alluded to some experiments which are being conducted by Prof. Fleming and Prof. Dewar upon the electrical resistance of metals and alloys. He gave this as an example of how a pure scientific research may become available for a scientific investigation, which has a direct practical bearing. As might easily be guessed, these experiments are being carried on at the exceedingly low temperatures which may be obtained by the boiling of liquid oxygen. We understand that the specific electrical resistance of metals, alloys, and carbon have been determined between the limits of +100°C. down to −197°C. the oxygen boiling in a vacuum of 25mm. Results of remarkable interest have been found, the increase of conductivity of the pure metals being very great, and there is a most striking difference between the electrical resistance of iron and nickel at the boiling point of water and at the boiling point of oxygen. Some of the experiments are being repeated on a larger scale, but we hope on an early occasion to publish the general results of this interesting research.

The establishment of a National Physical Laboratory for America is being discussed in the *Electrical World* of New York, and the co-operation of several Government departments is being sought. Dr. Webster remarks that Americans are willing to vote thousands of dollars for the construction of lighthouses, but are inclined to ask what the use is of determining the velocity of light with five-figure accuracy. Such "präcisionstechnik" has been suggested as one of the main objects of the institution which has been proposed for this country, and we fear that as long as this is put forward there will be a difficulty in inducing the English Government to do what the Reichstag has done for the Reichsanstalt. Governments may come and Governments may go, but the traditions of the Treasury, fortunately for the taxpayers, go on for ever. Some excellent physical work is done in Greenwich Park, some at the Mint on Tower-hill; a great deal of work of a miscellaneous, but exact, nature is done at Kew, some in Westminster at Old Palace-yard, and some in the kitchen under Richmond-terrace. The economy and greater efficiency which will be brought about by the centralisation of the various branches of the War Office in one building will soon be realised, and it is possible that some such inducement as this might lead to the concentration of the various existing Government laboratories.

Nothing has been heard for some little time of the Gilbert Club, but the main work which it was founded to undertake—the production of an English version of the *De Magnete*—has, we understand, been silently proceeding. The translation in rough form was indeed completed some two years ago, since which date the successive chapters have been under revision by members of the editing committee of the Club. The revised version will shortly be completed, when the work will be published with as little delay as possible.

In connection with scientific clubs having for their *raison d'être* a more or less veiled form of hero-worship, it is interesting to note that the Japanese have gone far beyond us in this respect. Within the precincts of Tokio University there exists, according to the *Japan Mail*, a Newton Club which was originally founded by three undergraduates, Messrs. Fujisawa, Tanaka, and Tanakadate, whose names have since become widely known. The professors, graduates, and students of the mathematical, astronomical, and physical classes of the University are alone eligible for membership. The annual festival of the club is held on the anniversary of Newton's birth, which took place on December 25th, 1642 (O.S.). The constitution of the *Newton Kai* like the idea itself is worthy of imitation; there is no President, a portrait of Sir Isaac Newton presiding instead, there are no written records and no minutes, but plenty of pleasant social intercourse marked by many strikingly original features.

We called attention some little time ago to the deadlock which had arisen in France in the matter of electric lighting in consequence of municipalities having granted broad concessions to gas companies, concessions which are now found to practically preclude the granting of similar privileges to electric lighting concerns. The mania for exclusive concessions, nevertheless, still prevails.

Quite recently the town of Saint-Claude has given a M. Louis Passot the sole right during forty years of running electric wires overhead and underground, in return for which this gentleman binds himself to lay down plant for the supply of current for 10,000 16-c.p. lamps and for motors to the extent of 650 H.P., and in addition to save the town harmless

Digitized by Google

in the event of an action by the local gas company. There is the usual saving clause permitting a modification of the contract in the event of the electric light being either superseded or fundamentally improved, but should any necessity arise for the enforcement of the clause it will probably prove as ineffective as have the corresponding clauses in gas concessions. Exclusive privileges of this kind are direct incentives to scamping, especially if lurking in the background there is a possibility of peremptory revocation. It is, therefore, perhaps a matter for thankfulness that there is only one quality of electricity, so that as long as there are stringent regulations with regard to the maintenance of a standard pressure at the consumers' terminals, and heavy fines for breakdowns, some of the worst results of the system of legalised monopoly might be avoided.

In the *Electrical Engineer* of New York an interesting correspondence is being published on the subject of the United States Government purchasing submarine cables abroad notwithstanding that they, like private individuals, have to pay 85 per cent. *ad valorem* tariff on the import. Some of the correspondents, who are all cable manufacturers, seem to think that this duty adds to the cost of the cable to the State, but one points out that the amount is simply paid by one Department to another, and does not really affect the cost to the Government.

Mr. Brixey naturally recommends "kerite" as a reliable substitute for gutta percha, but it is only necessary to say that no one would at present dream of manufacturing a long cable with such an insulator. Another firm, said to be the only makers of gutta percha cables in the States, offers to make and lay seven miles of cable for Lake Huron at $1,500—say £300—per knot. This seems to be a very high figure, as such a cable ought not to cost f.o.b. more than £100 to £110 per knot. In fact, the writer in question admits having offered to make 12 miles of cable at the latter figure, adding "and the English beat us at that." Incidentally, also, he throws some light on the effect of free trade, saying—"It is true there are no manufacturers in the United States capable of making the long ocean cables, as that requires *ships* to lay, as well as factories to make, and since iron wire is the largest item of cost, and that is much cheaper in Europe than in this country, as are also the labour and the ships, the long cables cannot be made here. Of course we could have no Protection on them."

Here is a clear instance of the result of Protection, which, by increasing the cost of materials and labour, gives England a practical monopoly of a large and important branch of manufacture. It appears to be clear that the United States Government are likely to get their cable more cheaply here, to say nothing of the fact that our manufacturers, having a vastly greater experience than the Americans in submarine cable work, are likely to supply a better and more durable article. At the same time the logical outcome of Protection would be to employ local contractors even though the consumer would be the loser by doing so.

Among the early proposals for the industrial application of electricity was one for the purification or refining of iron. The details were never published, and, though the scheme was thrust upon the proprietors of the Gramme patent, they fought shy of it, and only the vague recollection remains of a pair of electrodes thrust in a ladle of molten iron. A M. Fraley proposes to surround a mould with a solenoid, through which alternate currents are to pass while the metal cools. The effect of these currents, according to the inventor, will be to make the structure of the metal perfectly homogeneous, to facilitate the disengagement of gases, and to avoid crystalline formation. The *Bulletin International d'Electricité*, which contains a brief note upon this invention, does not inform its readers whether the process has ever been tried.

Attempts have been made to produce powerful cast-iron magnets by circulating a continuous current round the moulds. If the current is turned on before the metal is poured, it refuses to run into the mould; if it is turned on suddenly immediately after the casting is run, part of the molten iron is ejected, and a large, spindle-shaped cavity is formed. In the absence of any information on the subject, it appears likely that a similar mutual repulsion of the interior parts would take place with alternating currents, and there is little *à priori* reason to expect the other advantages to which we have alluded.

Lightship Communication.—It was stated at the meeting of the Dover Town Council on Wednesday that the East Goodwin lightship is definitely to be telegraphically connected with Dover.

Leeds.—At a recent meeting of the Highways Committee of the Leeds Corporation the plans of the Yorkshire House-to-House Electricity Company were submitted, and were approved of, subject to certain conditions.

The Chicago Exhibition.—The dates for the dedicatory ceremonies are the 19th, 20th, and 21st October. A programme for the final, or actual dedication day, has been issued by the Council of Administration and the Committee on Ceremonies.

Society of Engineers.—The next ordinary meeting of this society will be held at the Town Hall, Westminster, on Monday, October 3rd, at 7:30 p.m., when a Paper will be read on "The Cleansing and Ventilation of Pipe Sewers," by Mr. B. A. Miller.

Heckmondwike.—At a public meeting of the ratepayers of Heckmondwike, on Tuesday, the proposal of the Electric Lighting Committee of the Local Board, that the needful plant for lighting the town by electricity should be laid down, was adopted by a large majority.

The French Telephones.—On January 1, 1890, there were 1,200 miles of telephone lines in France, and on January 1, 1892, 2,850; an increase of nearly 140 per cent. in two years. The total income accruing to the State from this source amounts at present to £220,000.

Electric Lighting in Finnland.—Following the lead of several of the principal Finnish towns, Helsingfors, Wiborg, Tammerfors, and Uhlenborg, for instance, Wasa is about to adopt the electric light. The whole of the plant, including steam engines, is to be suppliedby the Maschinenfabrik Oerlikon.

Carlow.—At Carlow, which Messrs. Gordon and Co. have been lighting for the last 14 months, nearly one-fourth of the total revenue of the Carlow Gas Company has, it is said, been diverted. So serious has the opposition become that on Wednesday night a circular was issued by the Gas Company notifying that any person using electricity would be at once

Digitized by Google

cut off from the gas mains. Messrs. Gordon are now preparing to supply the whole lighting of the town electrically. Surely this action on the part of the gas company, if correctly reported, is illegal.

The Walker Engineering Laboratories.—At the meeting of the Iron and Steel Institute on Wednesday Prof. H. S. Hele-Shaw read a Paper describing the Walker Engineering Laboratories, and the scheme of engineering instruction given in them. There are yearly four scholarships of £125 per annum tenable for three years, ten £100 exhibitions, and 20 £50 exhibitions tenable for one year. The total time which a student taking a regular course is expected to work in the college is from 25 to 30 hours per week.

A Cable Museum.—An exhibition of cables has been added to the Imperial Postal Museum in Berlin in a special "cable room." It contains both land and submarine cables, of which samples have been sent from prominent firms in various countries. There are also specimens of the older telegraph cables, demonstrating the havoc wrought by time and sea. Notable among these are specimens of two of the oldest cables, viz., the one laid between Dover and Calais in the year 1850, and the one laid in 1854 between the same two places.

The Mutual Action of Vacuum Discharges.—In a recent contribution on the action of vacuum discharge streamers upon each other, Dr. M. I. Pupin described experiments showing that two electric current filaments in a rarified gas may repel each other in cases where electrodynamic action would produce an attraction. The repulsion did not appear to be due to electrostatic action, but rather to "a strain in the vacuum produced by the peculiar distribution of the gas pressure resulting from the peculiar distribution of temperature."

The Electric Lighting of Bartholdi's Statue of Liberty.—The lighting of the statue of Liberty at the entrance of New York Harbour is to be improved. The Lighthouse Board are thinking of placing two 100 c.p. incandescent lamps in front of each of the 25 windows which form a coronet on the statue. These will be protected from the weather in glazed lanterns with reflectors at the back. Under the balcony of the torch an arc lamp of 2,000 c.p. is proposed, with reflectors arranged to throw light on the face of the statue, and also to throw a beam of coloured light upward.

Chicle as an Insulator.—An account has been received, says the *India Rubber World* of New York, of the production and exportation of chicle in the States of Campeche and Yucatan, Mexico. Chicle, the sap of the sapotille tree, is extracted like camphor, india-rubber and other gum, and the entire output, amounting to something like 50,000lb. last year, is exported to the United States, where it enters into the manufacture of chewing-gum. The market value of chicle is 1s. 3d. per pound. Chicle is an insoluble substance, and it is said to be now used extensively as an insulator, replacing india-rubber.

A Photograph of the Members of the Institution of Electrical Engineers.—A large photograph, measuring 18in. by 28in., has been sent us by Messrs. Barrauds, of Oxford-street. It represents a group of 539 members of the Institution of Electrical Engineers. Nearly 70 of the portraits show the full length, the figures being about 2in. high. The members were photographed separately, and arranged upon an architectural background afterwards. The majority of the portraits are very good, although necessarily small. A key to this photograph has been arranged, but the names are not given in alphabetical order.

Cambridge.—The Secretary of the Cambridge Electric Supply Company writes to correct an erroneous statement which appeared on page 527 of our last issue, which was to the effect that the pipes through which the main cables were to be laid had been buried up without first running the pilot wires, with the consequence that on commencing to lay the main cables it was found necessary to dig up the pipes again. The Secretary states that his Company has not yet commenced to run the main cables, and that the pilot wires were run through the pipes while the work was progressing. We are glad to insert this correction, but may add that the paragraph in question was not published without confirmation from Cambridge.

The Electrical Utilisation of Water Power in Italy.—Within recent years several schemes have been drawn up for the transmission of large quantities of water power to Turin, says *Industries*. Among these there is that of Messrs. Aguidio and Azari, engineers, who have asked for the concession of a large quantity of water power on the Italian side of Mount Cenis. In this scheme it is proposed to generate about 500 H.P. on the spot and transmit it to Turin—a distance of nearly 40 miles—for electric lighting and industrial purposes. This 500 H.P. may be doubled by utilising the fall of the River Cenischia, falling from a height of over 3,280ft. The water, which comes from the top of Mount Cenis, now feeds a basin of 60 square kilometres, surrounded by ice.

An Anti-Induction Device for Telephone Lines.—Herr von Dolivo-Dobrowolsky, in spite of the continuance of the "battle of the phases," has found time to fall foul of the German Post-office authorities, who have thought fit to absolutely prohibit the use of high-pressure electric lines in the vicinity of telephonic circuits. Herr Dobrowolsky's remedy is to place a small induction coil in the middle of any earthed telephone circuit liable to inductional disturbances; in this way the induced currents would neutralise themselves. Another suggestion is to employ two coils, one in the high-pressure disturbing circuit and another in the disturbed telephone circuit, and to so arrange and wind them that the induction of one coil upon the other is made to exactly cancel out the induction caused by the straight portions of the high-pressure circuit.

Electric Power for Tasmanian Mines.—The Australian Rights Purchase Association is about to lay down a large hydraulic plant for the purpose of generating electricity to supply light and power to the mines at Mount Zeehan and Dundas, Tasmania. The plant comprises 262ft. of piping, with an intake of 7ft. 3in. in diameter, gradually reduced to 15in., off which two nozzles are taken of a 4in. diameter each, to play upon a Pelton wheel which has a diameter of 5ft. The working pressure will be 100lb to the square inch, thereby giving 300 H.P. From this station current will be taken by overhead wires to the mines, 10 miles off, where the power will be available for the purposes of lighting, haulage, boring, and pumping. This scheme is said to be the initial one of its kind in Australia, and the largest applied to mining pursuits in the British Empire. The scheme originated from the fact of the extreme cost of mining in the district, owing to the want of roads suitable for the cartage of coal and machinery.

Fibre Graphite.—A new form of self-lubricating bearing under the name of "fibre graphite," has, says *Engineering*, been brought out in America. The bearings are made of a mixture of wood pulp and graphite. The graphite is carefully selected, to be free from grit, and is crushed to an impalpable powder. It is then thoroughly mixed with moist wood pulp, and pressed into moulds having perforated sides, through which the water can escape. After air drying the solidified mass it is soaked in a drying oil and thoroughly baked. The oil appears to serve as a cementing material, and gives the mass some of the toughness and elasticity of linoleum. These bearings have been run for upwards of three years on a line of shafting in the charging house of a foundry, under the coke loft, where they were exposed to dust and to a high temperature. During the whole of this period they have, it is said, run in the most satisfactory manner, and have never once been oiled. They have also been used for the spindles of textile machines running at speeds of 9,000 to 12,000 revolutions per minute, and it is claimed that careful tests show that less work is wasted in friction when these bearings are used than when the spindles ran in gun-metal bearings in the usual way.

Bradford.—The following is a more detailed account of the figures relating to the Bradford Municipal than that given on p. 526 of our last issue:—For the half-year ended on June 30th last the total expenses on revenue account were £1,573 2s. 9d., and the total revenue £3,215. 16s. 11d., leaving a trade profit of £1,642. 14s. 2d. The interest paid on loans out of that sum amounted to £677. 19s. 8d., and the contributions to the sinking fund were £577. 7s. 4d., leaving a net profit of £387. 7s. 2d., as stated in our last issue. The total liabilities at present in respect of loans were £42,341. 18s. 9d. The floating liabilities amounted to £47,836. 4s. Since the com

Digitized by Google

mencement of the works there has been paid in interest and on sinking fund account £5,625. 3s. 7d. The trade profit which has been made amounts to £4,825. 12s. 11½d. There was a loss of £1,079. 8s. 5d. on the first half-year's working; in the second half-year the loss was £732. 6s. 11d.; in the third, £315. 6s.; and for the half-year ended June, 1891, there was a loss of £30. 5s. 4½d.; the total loss being £2,157. 6s. 8½d. At the end of December last there was a net profit of £970 8s. 10½d., and at the end of June last the net profit was £387 7s. 2d. If the total net profit be deducted from the total net loss it will show a net loss of £799. 10s. 8d. still to be made up.

Cooking by Electricity.—Messrs. Crompton and Co. are giving close attention to the development of the use of electricity for domestic purposes, including cooking, and in order to bring the advantages of their apparatus before the public, they are showing it at various Exhibitions. Their latest exhibit has been at the Health Exhibition, Portsmouth, in connection with the Sanitary Congress, where they have succeeded in carrying off two prize medals and highest awards, one being for their improved electrical cooking apparatus. Mrs. Knight, the cook employed by the Sanitary Institute to demonstrate the use of the gas and other stoves on trial, prepared food by the electric cookers every day, and considered that the electrical apparatus was not only equal, but superior in many respects to the gas cooking appliances formerly employed. Altogether the innovation of competing with the makers of coal ranges and gas stoves has created great interest. We understand that it is the intention to introduce electricity as a sole cooking power in several large flats in the West End of London nearing completion, where it was formerly intended to install gas stoves. The supply companies will make a special reduction for current used for driving domestic machinery and cooking apparatus. The Health Exhibition at Portsmouth will remain open for a further three weeks.

The Associated Chambers of Commerce and the Telephones and Telegraphs.—At Wednesday's meeting of the Associated Chambers of Commerce the Newport Chamber laid before the conference a resolution condemning the policy of the postal authorities with regard to the telephones, which would, stated the resolution, have the effect of extinguishing trunk lines and would considerably hamper business transactions. The resolution was agreed to. It was agreed—"That, in the opinion of this Association, the extension of direct telegraphic communication between the component parts of the British Empire will facilitate defence, promote trade and investments, emphasise community of interests, and generally stimulate the development and consolidation of the Empire;" and another resolution was passed, on the initiative of the Wakefield Chamber, declaring "that it is unfair to the public that the telegraphic department of the Post Office should, for financial purposes, be treated as a separate establishment, thereby causing unwarrantable delay in carrying out urgent and much needed reforms. That, inasmuch as the postal establishment and its various departments are in their entirety a financial success, the time has arrived when an address of not exceeding six words should be allowed free of charge in all telegrams, and that where practicable telegraphic communication should be extended to the rural districts."

Gamgee's Devaporator.—An apparatus for condensing the exhaust of steam-engines is at work on an experimental scale at Church-street, Millbank, S.W. The inventor, Mr. John Gamgee, does not appear to aim at producing a vacuum, but claims that he returns all the exhaust into the boiler at nearly boiling point. The principle is difficult to understand, as the usual theory of the latent heat of steam is rejected, and the assertion is made that when steam is brought into contact with cold water there is a conflict, and it is this which engenders heat. The steam is passed through a number of tubes filled with water a few degrees below boiling point. It bubbles quietly among balls or other bodies offering a large surface, and is said to be condensed by "surface tension." The apparatus, which we have seen in action, is connected to a small steam-engine, but the arrangement is, we understand, not to scale, and the usefulness of the system cannot therefore be estimated. The action appears to be that of an air condenser, in which the steam is condensed through the intermediate assistance of a mass of water which is kept in motion. A great intricacy of pipes, valves, tanks, &c., and the introduction, by way of explanation, of a glass tube containing ether at a low pressure, boiling by the warmth of the hand, served rather to complicate the matter. This kind of invention ought not to be condemned merely as "unorthodox," and we understand that it is being carefully examined by experts, who, we hope, will be able to explain the working without throwing over any fundamental principles of physics.

The Electricity of Waterfalls.—In a recent number of *Wiedemann's Annalen* some notes on this subject are contributed by Ph. Lenard. Numerous observations and experiments concerning the electricity developed by water falling in drops, jets, or waterfalls have led to the following general conclusions: Drops of water falling on to water or a wetted body generate electricity. Water is electrified positively, air escapes negatively electrified from the foot of the fall. Jets breaking up into spray make the electrification more apparent. Slight impurities in the water diminish the effect considerably. Other liquids and gases also produce electrification, but differing in intensity and sign. The essential conditions of electrification are the concussions among the waters themselves and against the wet rock. The friction against the rock and the fall of the earth potential are of secondary importance, while no effect is due to the water's fall through air and its dispersion in it. The author explains these phenomena by the sudden diminution of the water surface, and the convection of negatively charged air away from the foot of the fall. A jet of water falling from an insulated tank into an insulated pail electrified the latter positively, while the negative electrification of the surrounding air grew to several hundred volts. A steady increase of potential was also produced by drops of water falling at the rate of two per second. Sparks were sometimes obtained from waterfalls, and in all cases the air was found to be negatively charged, though this charge was diminished if air bubbles were driven under water.

The Measurement of High Temperatures.—At the last meeting of the Institution of Civil Engineers for the Session 1891-92 Prof. Roberts-Austen read a Paper on this subject. He pointed out that there were many operations incidental to the work of the engineer involving the use of high temperatures, which should be accurately measured, because a difference of 20deg. at a "bright red" heat might be of vital importance to the success of an operation. Siemens, and more recently Callendar, had shown that very trustworthy results might be obtained by employing the increased resistance of a platinum wire, due to heating it, as a measure of the temperature to which the wire was raised. On the other hand, Prof. H. le Chatelier had perfected the use of thermo-junctions, the electrical equilibrium of which was disturbed by heat, and the measurement of the difference of potential thereby produced, afforded a means of ascertaining the temperature to which the junction was subjected. Prof. Roberts-Austen then described at length his method of rendering the indications of the Le Chatelier thermo-junction self-recording, and he proceeded to show what degree of confidence might be placed in the measurement of high temperatures, incidentally comparing the testimony afforded by an air-thermometer and by a thermo-junction as to the temperatures of highly-heated bodies. The meeting points of gold (1045° C.) and of palladium (1500° C.) were measured by the aid of a thermo-junction, a spot of light from a galvanometer with which the thermo-junction was connected, traversing a scale 30ft. long. Electric pyrometers were, however, in the author's opinion, too costly, and were not sufficiently simple for daily use in works, and it was fortunate, therefore, that a less complicated instrument of sufficient accuracy had also been furnished by Le Chatelier, who had thereby increased the debt due to him by the scientific and industrial world. His new optical-pyrometer, based upon the photometer of Cornu, was described at length, and a series of measurements of high temperatures made by its aid in the furnaces of the Royal Mint, and in various metallurgical works in this country and on the Continent, were given.

GENERALISATION OF MERCATOR'S PROJECTION PERFORMED BY AID OF ELECTRICAL INSTRUMENTS.

BY LORD KELVIN, P.R.S.

The following mode of generalising Mercator's Projection is merely an illustration of a communication to Section A of the British Association at its recent meeting in Edinburgh, entitled "Reduction of every Problem of Two Freedoms in Conservative Dynamics to the Drawing of Geodetic Lines on a Surface of given Specific Curvature." An abstract of this Paper appeared in *Nature* for August 18th, p. 386.

In 1568 Gerhard Krämer, commonly known as Mercator (the Latin of his surname), gave to the world his chart, now of universal use in navigation. In it every island, every bay, every cape, every coast-line, if not extending over more than two or three degrees of longitude, or farther north and south than a distance equal to two or three degrees of longitude, is shown very approximately in its true shape; rigorously so if it extends over distances equal only to an infinitesimal difference of longitude. The angle between any two intersecting lines on the surface of the globe is reproduced rigorously without change in the corresponding angle on the chart.

Mercator's chart may be imagined as being made by coating the whole surface of a globe with a thin inextensible sheet of matter, sheet india-rubber, for example (for simplicity however imagined to be perfectly extensible but inelastic); cutting away two polar circles to be omitted from the chart; cutting the sheet through along a meridian, that of 180deg. longitude from Greenwich for example, stretching the sheet everywhere except along the equator, so as to make all the circles of latitude equal in length to the circumference of the equator. and stretching the sheet in the direction of the meridian in the same ratio as the ratio in which the circles of latitude are stretched, while keeping at right angles the intersections between the meridians and the parallels. The sheet thus altered may be laid out flat or rolled up, as a paper chart.

What I call a generalised Mercator's chart for a body of any shape spherical or non-spherical, is a flat sheet showing for any intersecting lines that can be drawn on a part of the surface of the body, corresponding lines which intersect at the same angles. One Mercator chart of finite dimensions can only represent a part of the complete surface of a finite body, if the body be simply continuous; that is to say, if it has no hole or tunnel through it. The whole surface of an anchor ring can obviously be mercatorised on one chart. It is easily seen for the case of the globe that two charts suffice to mercatorise the whole surface; and it will be proved presently that three charts suffice for any simply-continuous closed surface, however extremely it may deviate from the spherical form.

In *Liouville's Journal* for 1847, its editor, Liouville, gave an analytical investigation, according to which, if the equation of any surface whatever is given, a set of lines drawn on it can be found to fulfil the condition that the surface can be divided into infinitesimal squares by these lines and the set of lines on the surface which cut them at right angles. Now it is clear that if we have any portion of a curved surface thus divided into infinitesimal square allotments, that is to say, divided into infinitesimal squares with the corners of four squares together, all through it, we can alter all these squares to one size, and lay them down on a flat surface with each in contact with its four original neighbours; and thus the portion of surface given is mercatorised. Except for the case of a figure of revolution, or an ellipsoid, or virtually equivalent cases, Liouville's differential equations are of a very intractable kind. I have only recently noticed that we can solve the problem graphically (with any accuracy desired if the problem were a practical problem, which it is not) by aid of a voltmeter and a voltaic battery, or other means of producing electric currents, as follows:—

1. Construct the surface to be mercatorised in thin sheet metal of uniform thickness throughout. By thin I mean that the thickness is to be a small fraction of the smallest radius of curvature of any part of the surface.

2. Choose any two points of the surface N, S, and apply the electrodes of a battery to it at these points.

3. By aid of movable electrodes of the voltmeter trace an equipotential line, E, as close as may be around one electrode, and another equipotential line, F, as near as may be around the other electrode. Between the two equipotentials E, F, trace a large number, n, of equi-different equipotentials. Divide any one of the equipotentials into n equal parts; and through the divisional points draw lines cutting the whole series of equipotentials at right angles. These transverse lines and the equipotentials divide the whole surface between E and F into infinitesimal squares (Maxwell, "Electricity and Magnetism," § 651).

4. Alter all the squares to one size and place them together as explained above. Thus we have a Mercator chart of the whole surface between E and F.

N and S of our generalisation correspond to the north and south poles of Mercator's chart of the world, and our generalised rule shows that a chart fulfilling the essential principle of similarity realised by Mercator may be constructed for a spherical surface by choosing for N, S, any two points not necessarily the poles at the extremities of a diameter. If the points N, S are infinitely near one another, the resulting Mercator chart for the case of a spherical surface is the stereographic projection of the surface on the tangent plane at the opposite end of the diameter through the point C, midway between N and S. In this case the equipotentials and the stream lines are circles on the spherical surface cutting NS at right angles, and touching it, respectively.

For a spherical or any other surface we may mercatorise any rectangular portion of it, A B C D, bounded by four curves, A B, B C, C D, D A, cutting one another at right angles as follows:—Cut this part out of the complete metallic sheet; to two of its opposite edges, AB, DC for instance, fix infinitely conductive borders. Apply the electrodes of a voltaic battery to these borders, and trace n equidifferent equipotential lines between A B and D C. Divide any one of these equipotentials into n equal parts, and through the divisional points draw curves cutting perpendicularly the whole series of equipotentials. These curves and the equipotentials divide the whole area into infinitesimal squares. Equalise the squares and lay them together on the flat, as above.

If we have no mathematical instruments by which we can draw a system of curves at right angles to a system already drawn, we may dispense with mathematical instruments altogether, and complete the problem of dividing into squares by electrical instruments as follows:—Remove the conducting borders from A B, D C; apply infinitely conductive borders to A D and B C, apply electrodes to these conducting borders, and, as before, draw n equidifferent equipotentials. This second set of equipotentials, and the first set, divide the whole area into squares.

ON THE THERMIC VARIATION OF THE ELECTRIC RESISTANCE OF MERCURY.*

BY CH. ED. GUILLAUME.

The discrepancies which exist between the results of recent determinations of the thermic variation of mercury standards of resistance induced me to take the matter up again with improved electrical apparatus, and utilising the thermometric resources of the Bureau International des Poids et Mesures. A first set of investigations, carried out in the course of the winter of 1889-90, yielded a result which I thought was not free from certain systematic errors. I recommenced the entire work in the following winter, profiting by the experience acquired.

Method.—A mercury standard of about one ohm, brought in succession to different temperatures, was compared with another standard which was maintained at an invariable temperature; the resistances being adjusted so that their positive and negative deviations were approximately of the same amplitude in the temperature interval of the comparisons. The contacts were eliminated by the following process:—By the side of each standard a glass vessel containing a few kilogrammes of mercury was placed; this mercury being kept at the same temperature as that of the neighbouring standard. Let I. and II. be the

* *Comptes Rendus*, Vol. CXV., No. 11.

Digitized by Google

standards, and I'. and II'. the corresponding vessels. I arranged the following circuits successively in the same branch of the bridge :—

Bridge—I.—II'.—Bridge, Bridge—I'.—II.—Bridge.

By this means the entire circuit of the rods and contacts remained invariable. In the first investigations the difference between the standards was measured by the resistance of a portion of a brass wire accurately standardised. In the second series each determination was moreover repeated by introducing

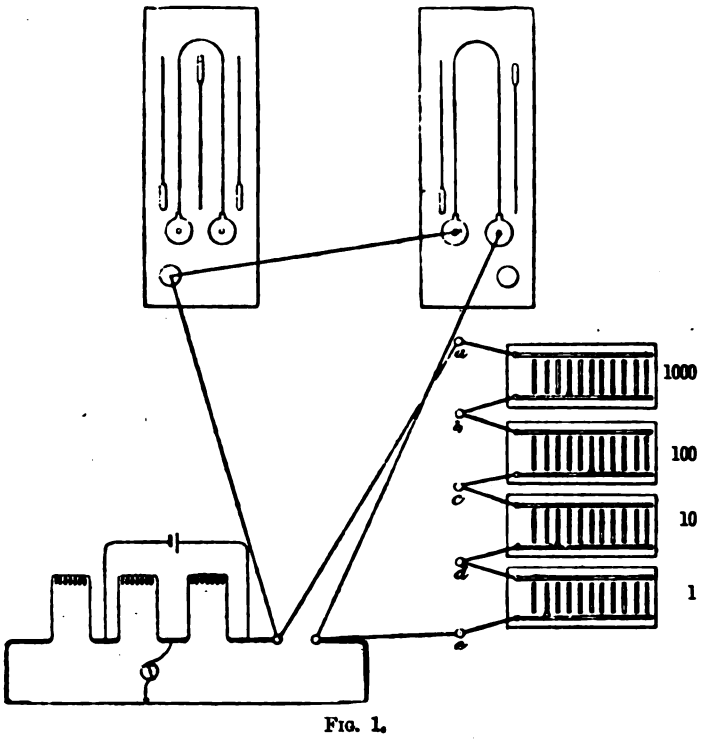

Fig. 1.

as a shunt across the terminals of the bridge a resistance, such as to bring the galvanoscope back to zero. Fig. 1 represents these arrangements. In employing this method the error of comparison depends on the relative error of the shunts multiplied by the ratio of each resistance to its shunt; in my measurements this ratio never exceeded $\frac{1}{30}$. The accuracy sought for being of the order of one in a hundred thousand, it was only necessary that the shunts should be known to about $\frac{1}{3000}$, which presented no difficulty whatever.

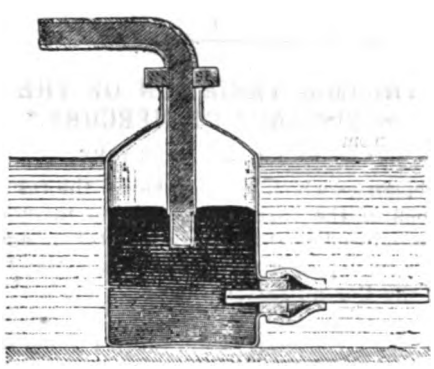

Fig. 2.

Standards and Contacts.—In order not to be too limited in the current strengths to be employed, I chose for the construction of the standards fairly large tubes, containing about 30 grammes of mercury per ohm. In my first investigations the tube opened directly into the terminal cup (Fig. 2), but fearing a disturbing contact effect at the portion of the tube protected by the cork and india-rubber pipe, the first set of cups was replaced in the second series of experiments by some which were provided with a lateral tubulure, allowing the standard to attain along its entire length the temperature of the bath (Fig. 3). At the beginning the contacts were effected by a large copper bar fitted with a platinum capsule, and protected by a glass tube and an india-rubber tube (Fig. 2). I next took to the contacts described by M. Benoit (Fig. 3); and finally adopted a mixed form, which consisted in capping the first contact with a glass cup (Fig. 4).

Comparisons.—In the first set of tests I carried out 37 series of comparisons in water, and 8 series in ice and vapour of water, these latter being with a vertical standard. In the second set I carried out 32 series of measurements by means of the wire, and as many by the aid of shunts. Each series comprised 28 measurements. The measurements were made at about every two degrees between 0° and 61°, and they were distributed in such a manner that I came back on several occasions to the high and low temperatures to eliminate a possible variation of the standards with time, a variation which, I may add, was not observed.

Results.—In the case of my first investigations I shall only give the apparent resistance of mercury in glass as a function of the centigrade scale of hard glass thermometers. The formula I arrived at is as follows :—

$$r_t = r_0 (1 + 0{\cdot}0008726\, t + 0{\cdot}000001057\, t^2).$$

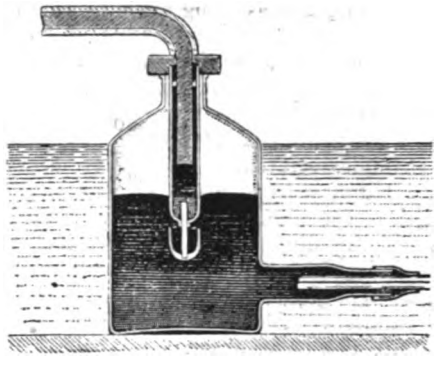

Fig. 3.

Fig. 4.

The complete results of my latest determinations are as follows:—

(I.) Apparent variation of the resistance of mercury in hard glass as a function of the mercury thermometer.

a. By the wire :—

$$r_t = r_0 (1 + 0{\cdot}00087537\, t + 0{\cdot}0000010621\, t^2).$$
$$\pm \qquad 55 \qquad \pm \qquad 89$$

b. By the shunts :—

$$r_t = r_0 (1 + 0{\cdot}00087671\, t + 0{\cdot}0000010469\, t_2)$$
$$\pm \qquad 44 \qquad \pm \qquad 72$$

(II.) As a function of the normal scale :—

a. ..... $r_T = r_0 (1 + 0{\cdot}00088023\, T + 0{\cdot}0000010063\, T^2)$,

b. ..... $r_T = r_0 (1 + 0{\cdot}00088157\, T + 0{\cdot}0000009909\, T^2)$.

Making use of the determinations of MM. Benoit and Chappuis with regard to the expansion of glass, we find the real variation of the specific resistance of mercury as a function of the normal scale to be as follows :—

a. ..... $\rho_T = \rho_0 (1 + 0{\cdot}00088745\, T + 0{\cdot}0000010181\, T^2)$,

b. ..... $\rho_T = \rho_0 (1 + 0{\cdot}00088879\, T + 0{\cdot}0000010022\, T^2)$.

The results obtained by the two methods are very concordant, as one can see by merely inspecting the formulæ, and noting that the values of the terms T and T^2 sensibly compensate each other. The following table gives the values of the apparent resistance of mercury in glass, as a function of the normal scale, calculated from the formulæ II*a* and II*b* :—

—	Values obtained.	
T.	Wire.	Shunts.
0	1·00000	1·00000
10	1·00890	1·00891
20	1·01801	1·01803
30	1·02731	1·02734
40	1·03682	1·03685
50	1·04653	1·04656
60	1·05644	1·05646

Digitized by Google

The difference between the last and first determinations justifies my fear as to systematic errors in the latter.

In making use of the above figures for the reduction of experiments relating to the determination of the ohm, we shall find somewhat higher values than those which have been given by most observers, so that the average reduced from good determinations attains, broadly speaking, the value

$$106{\cdot}3 \frac{\text{cm.}}{(\text{microlitre})^{\frac{2}{3}}} \text{ Hg. at } 0°.$$

UNDERGROUND HAULAGE BY ELECTRIC LOCOMOTIVES.

At a recent meeting of the Charleroi Committee of Mining Engineers, M. Clément Baily, engineer to the Marles Collieries, read a communication on electric haulage in mines.

As our readers will be aware, electric haulage by the overhead system has been practised with complete success at a salt mine in Zankeroda, Saxony, for a number of years. Although this plant has demonstrated the commercial advantages of this class of haulage, yet the sparking between the trolley and the conductor, and the rolling wheels and the metals has prevented the application to coal mines, excepting in one instance, as far as our memory serves us. This is at Wharncliffe Silkstone Collieries, in Yorkshire, where a 4 H.P. locomotive was installed by Mr. Albion T. Snell some three years ago. But it seems, according to M. Baily, that there is no gas at the Marles Collieries, and so the Managing Director felt justified in trying electric haulage after seeing the success attained at Zankeroda.

The installation determined on was designed to run two locomotives of 10 H.P., and to be also available for lighting purposes. The E.M.F. selected is said to be 100 volts, and the current per locomotive 30 amperes; but obviously there is some mistake, in the pressure probably. The motors are series wound, with a shunt to the field windings, so as to control the torque for a given current. The gearing consists of two reductions, one being bevelled wheels. The current is said to be collected by *two* small trucks drawn along by the locomotive, we presume them to be little trolleys running on the overhead wire, and apparently the metals are not used as a return. The over-all dimensions of the locomotive are 8ft. long, 2ft. 5in. wide, and 5ft. high, and the total weight with ballast is about 2½ tons. The general dimensions, weight, and design seem to be approximately similar to those of the locomotive recently installed at the Greenside Lead Mines in Cumberland, and referred to in our issue of August 26th, p. 445.

As for M. Baily's deductions they tell us nothing new, indeed we could have foretold them. He says that the grades should be uniform so that the maximum current of the rheostat is never exceeded; light loads are not commercially profitable owing to the relatively great weight of the locomotive; and it is necessary to run at or near to the speed for which the motor is designed. He also finds that the best results are obtained with the field magnets unshunted, *i.e.*, with the wire carrying the whole of the current in the armature. The figures given with reference to the cost of running, &c., are not of interest, since the scale of charges and conditions of working are so different in our country.

The ultimate conclusion arrived at by M. Clément Baily is that haulage by electric locomotives is permissible in non-fiery coal mines, and will be commercially advantageous. We have always been of this opinion, and feel some little surprise that electric locomotives have not superseded horses in many of our English mines.

THE LIVERPOOL OVERHEAD RAILWAY.*

BY J. H. GREATHEAD, M.I.C.E.

The question of improved and more rapid means of transit for passengers is occupying attention in many of the great cities at the present time. With the extension of areas covered the question becomes increasingly pressing. In London it has been under consideration for many years, and during the last Session a Joint Committee of the two Houses of Parliament reported favourably upon a number of proposed underground electric railways of the type of the City and South London Railway, completed and opened for traffic in 1890. In Paris, Berlin, and Vienna, similar railways have been promoted and are under discussion; while in New York, a city long since provided with elevated railways and tramways along most of the main thoroughfares, a Rapid Transit Commission has lately reported in favour of an extensive system of underground electric railways, and in other American cities, notwithstanding the rapid development of electrically worked tramways, additional facilities in the shape of over and underground lines are being considered. This question, then, is an important one for engineers and the iron industries. All the proposed underground lines, are, since the construction of the City and South London Railway, proposed to be made of iron, and that material must necessarily enter largely into the construction of any overhead railway.

The particular railway under discussion is composed almost entirely of wrought iron. The line, now approaching completion, traverses the whole length of the famous Liverpool docks, a distance of about six miles. The extensions north and south authorised last Session go beyond the docks and away from the river in order to give better access between the residential neighbourhood reached by them, the docks, and the heart of the city. With the exception of a short length where the line passes under the Lancashire and Yorkshire Railway coal sidings, the railway is, as its name indicates, overhead, and for the most part just over the lines of the original Dock Railway, which is upon the surface. The Overhead Railway consists generally of plate-iron girders supported upon channel iron columns, and carrying an iron flooring, upon which the permanent way is laid direct, without the usual intervening ballast. With the exception of some half-dozen spans, the line has been constructed without the use of scaffolding, and with very little interference with the traffic, either of the docks or of the streets.

The railway is to be worked by electricity, generated at a station, for which twelve of the arches, forming the viaduct which carries the coal sidings of the Lancashire and Yorkshire Railway, have been appropriated, near the Bramley Moore Dock, and about the middle of the line. At this station are three engines, each capable of working up to 400 indicated H.P., and each driving a separate Elwell-Parker dynamo. The electricity will be carried north and south along the railway by a steel conductor, placed on porcelain insulators, supported upon cross timbers between the rails of each line. Hinged collectors of cast iron, sliding upon this conductor, will make the connection between the motors upon the train and the dynamos at the generating station. The motors are not placed (as on the City and South London Railway) upon a separate locomotive, but are carried by the passenger carriages themselves. A train will consist of two carriages, each to seat 56 passengers, and provided with a motor at one end. The carriages will be so coupled as to give a motor at each end of the train, and the motors will be so connected together as to be controlled from either end by the driver, who will always travel at the front end, changing ends upon arrival at a terminus, and carrying with him a key, without which the motors cannot be operated. All the carriages will be exactly alike, and will contain compartments for two classes of passengers, with through communication from end to end of the train under the control of the guard. A train loaded with passengers will weigh about 40 tons. The trains will be lighted by electricity, and are fitted with the Westinghouse brake, deriving its compressed air from a reservoir on the train, the reservoir being charged after each journey. This system of working the brakes answers well on the City and South London Railway.

The generating station will contain at first six boilers of the Lancashire type, each 30ft. long by 8ft. diameter, with a working pressure of 120lb., stoked mechanically. The engines are horizontal, compound, condensing, by Messrs. John Musgrave and Sons, Bolton. It is intended to commence running with a five minutes' service of trains, but the generating plant is designed to be capable of working a three minutes' service, and the journey from end to end of the railway (inclusive of stoppages) to be performed in half an hour. There are thirteen stations upon the dock portion of the line, and a novel feature on the railway will be a system (Timmis's) of automatic signals at all the intermediate stations, in place of the ordinary signalling arrangements. These signals will be electrically worked by the trains themselves, and considerable saving in the working expenses will result. The total cost of the railway, including equipment, will be about £80,000 per mile. Mr. J. W. Willans is the contractor for the works, and the Electric Construction Corporation are providing the electrical equipment and the carriages. The engineers, Sir Douglas Fox and the author, have been represented on the work by Mr. Francis Fox and Mr. S. B. Cottrell, and Mr. F. Huddleston has had charge of the work (for Mr. Willans), to whom is due the credit for the design of the tilting and swing bridges. It is intended to open the line for traffic very shortly.

* Abstract of a Paper read before the Iron and Steel Institute at Liverpool, Tuesday, September 20, 1892.

STEEL-PLATE PORTRAITS

Of Willoughby Smith, W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, G.C.M.G.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz, Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), and Lord Rayleigh, F.R.S., have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

LINES OF FLOW.

"I set Prof. W. THOMSON a prop.," wrote MAXWELL to Mr. CAY in 1865, "which I had been working with for a long time. He sent me eighteen pages of letter of suggestions about it, none of which would work; but on Jan. 3, in the railway from Largs, he got the way to it, which is all right; so we are jolly, having stormed the citadel, when we only hoped to sap it by approximations. The prop. was to draw a set of lines like this— so that the ultimate reticulations shall all be squares. The solution is exact, but rather stiff." This problem MAXWELL wished to solve "in order to calculate the thickdom or viscosity" of a gas. These "reticulations" are familiar to those who have turned over the leaves of his treatise on "Electricity and Magnetism" in the diagrams which placed FARADAY'S lines of force upon a sound mathematical basis. Similar reticulations formed by the intersection of imaginary lines may be found by an effort of the scientific imagination throughout all nature. Wherever there is a flow of heat, isothermal surfaces cut the lines of flow at right angles; in the more gross and mechanical phenomena of sound the direction of propagation is at right angles to the wave front, however that may be contorted, and so, also, with light. In all these and scores of other cases, a set of lines may be drawn "so that the ultimate reticulations shall be all squares." The most well-known

Digitized by Google

instance is one to which we have already alluded—electric lines of force and equipotential surfaces. MAXWELL has given a geometrical construction by which these may be drawn with ease; Prof. W. G. ADAMS has shown how the actual lines, if we may use the expression, may be pricked off on a sheet of tinfoil, a most interesting process, which might be used to solve extremely complicated problems of flow. The Rev. F. J. SMITH only last month sent to the British Association a description of a very simple method of drawing lines of force, a method which, in the absence of the author, seemed to be little appreciated and even misunderstood. When graphical methods become more popular, a name will perhaps be found for these curves which in one case we call equipotential surfaces and lines of current-flow, in another isothermal surfaces and lines of heat-flow, in terrestrial magnetism isodynamic and isogonic lines, and in radiation a wave-front and ray.

Difficult as the mathematics may be, which analyse and describe these lines and surfaces by Liouville's differential equations, the curves tell a plain tale by their very shapes; qualitative information this, and subordinate in scientific importance to quantitative, but yet, to a certain extent, complete in itself. Quite distinct from these lines of flow and the surfaces normal to them, there are many other examples of sets of lines which have the property that, however they may twist and turn, their reticulations are all squares. Such are the lines of compression and extension in a girder, contours and lines of slope on a map, and leaving forces and curvatures, the well-known lines of latitude and longitude obey the same general conditions. Most of our readers have probably looked upon lines of latitude and longitude as mere conventional helps in measurement by which the sailor can so conveniently prick his position on a chart, and without which an index to an atlas would be scarcely possible. The reason why lines of longitude always intersect lines of latitude at right angles seems to be obvious, as obvious as that an inextensible sheet of paper when folded and creased presents a straight edge; but equally difficult to explain off-hand. Nor is it our intention to attempt an explanation; to explain would be but to state at some length the exact conditions of the case. But we have to call attention to an article which Lord KELVIN has contributed to our columns, in which he brings forward the remarkable generalisation of the identity of what may be called geodetic lines with electric lines of flow and equipotential surfaces. This is no mere analogy, but the discovery that the same geometrical principle is the basis of the two systems of curves, and the identity of this principle having been shown, a number of corollaries are at once evident. Lord KELVIN has, we believe, "got the way to" several interesting "props." in the train since his journey from Largs in 1865, and his early interest in the present one may have led to this latest application in a most unlikely direction. This problem is interesting in that it is, as treated by Lord KELVIN in the article which will be found in our present issue, purely and strictly geometrical, geometrical indeed in the literal etymological sense. A school of Cambridge mathematician are said to have looked forward to the day when a mathematical treatise should be written entirely in algebraic symbols, without a word of vulgar English language. The reverse is to be found in the present article. Not only is there not a single algebraic symbol, but the geometry is so simple that no diagrams are necessary. The problem is confessedly not apractical one, but it is remarkable that it may be solved by means of a voltmeter and a battery with any desired accuracy. The interest lies in the inductive reasoning by which we pass from particulars to generals. Induction is defined by MILL as the process by which we conclude that what is true of certain individuals of a class is true of the whole class. This, when logically applied, extends our knowledge by important strides from the known to the unknown, compared with the more easy but slow process of arriving at conclusions from experimental premises. An analogy between magnetic resistance and electrical resistance, or rather between magnetic flow and electric current, was described by Mr. KAPP in his Paper on the "Predetermination of the Characteristics of Dynamos" in 1886. He compared a magnet to a battery submerged in a badly-conducting medium, and observed that "it is impossible to say exactly in what manner these leakage currents are distributed." The difficulty lies in the definition of the poles. Prof. ADAMS has shown how lines of flow and equipotential surfaces may be traced in three dimensions, the poles being practically points. The submerged battery is more closely analogous to the magnet and the problem is more difficult. We have already suggested in these columns that the magnetic lines of force and the isodynamic surfaces surrounding a dynamo might easily be drawn, and the ultimate reticulations of these would all be squares.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 506.*)

18. Buoyed End Inboard.—As the ship approaches the position where the other end of the cable was left buoyed, a sharp look-out is kept to sight the buoy in time to bear down directly upon it, and should this occur at night it is generally possible with the aid of the search-light to sight it two miles off. As

FIG. 64.—Unmooring Buoy at Sea.

soon as the ship is up to buoy a boat is lowered with four or five hands to unmoor her, this manœuvre being illustrated in Fig. 64 from an instantaneous photograph by Mr. Norman H. Allen, third officer of the Eastern Company's ship the "Electra." Getting the boat up to buoy and hanging alongside is not an easy job in a heavy current or tide way, such, for instance, as rushes through the straits of Lombok and about the neighbouring islands east of Java, near to which the three Australian cables pass. In such strong currents the boat has to be assisted with a line from the ship. To get the buoyed end on board a length of three-by-three rope is passed over one of the bow sheaves from the picking-up drum, and the first thing to be done by the boat's crew is to make this fast to the bridle chain on the

* All rights reserved.

Digitized by Google

buoy. The end of the bridle is first detached from the slip hook on the side of the buoy, taken in the boat, and the end of the drum line from the ship shackled on. Meanwhile, on board, the other drum over which the payed-out cable is wound is held stationary by setting up the brake, and then thrown out of gear with the engine shaft. Where there is one engine and one train of gear to both drums the latter can be thrown in or out of gear with the engine by shifting the pinion driving the brake-wheel shaft; and when up to buoy the pinion driving the paying-out drum is thrown out (first, of course, putting brake on) and the pinion on the other drum, used for

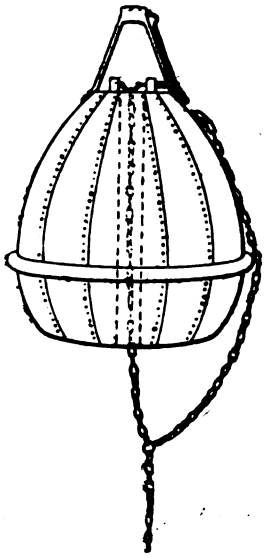

FIG. 65.—Buoy with Central Mooring Chain.

picking up buoyed end, put in gear. Some ships have recently been fitted with a separate engine and separate trains of gear to each drum, giving independent control of each.

On the signal from boat that drum line is made fast to the bridle, the ship heaves in steady and presently takes the whole weight of the mooring chain, leaving the end of this chain on buoy slack. It only remains then to slip this chain, leaving the buoy free and ready to be taken on board again. The ship gives the signal "Knock up" for this chain to be slipped as soon as she has all the strain on board. The slip hook to which this refers has been previously described, suffice to say here that knocking up the washer allows the hook to fall and end of chain to drop free. Another manner of attaching the mooring chain to the buoy a good deal in favour is shown in

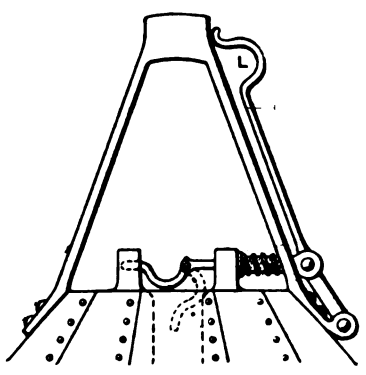

FIG. 66.—Slip Hook for Central Chain.

Fig. 65. Instead of reeving the chain through a ring at the bottom of buoy and attaching end to a slip hook on the side, as previously described, the chain is taken up directly through a tube in the centre, and attached to a slip hook at the top. The latter is constructed as shown in Fig. 66, from which it will be seen that by pulling outwards the lever L at the side the slip hook falls and disengages the chain. The buoy being free, ship heaves in again on drum until the cable appears, when after detaching the mushroom, a sufficient length of cable is hauled in to make the final splice. While heaving in, the strain gradually increases as the cable is raised, and this has the effect of pulling the ship in this direction, thus increasing the strain on the paying out end. To allow for this the brake on the paying out drum is eased as the strain comes on. This operation at the bows is sketched in Fig. 67, the buoy rope being heaved in over one sheave and the payed-out cable being slacked out over another.

This work used to be performed with one drum, before paying out over the bows became a general practice, and the

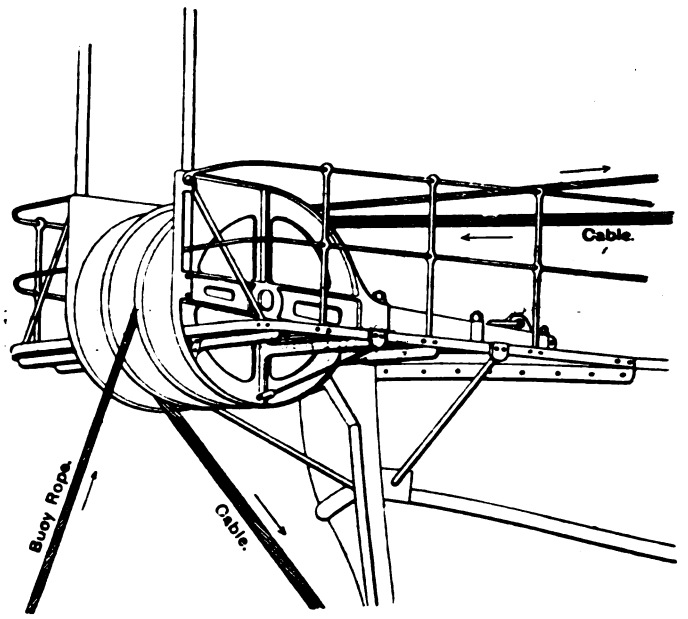

FIG. 67.—Recovering Buoyed End, and Slacking Payed-out Cable.

gear added to suit the requirements. With only one drum the rope for heaving buoyed end was wound round the opposite way to the cable being payed out, and in this manner as much cable was payed out as rope was hauled in. This meant considerably more slack payed out than necessary, and hence the use of two drums forward.

When sufficient length of cable is heaved in to allow for making the splice, manilla slip ropes are made fast (stopper fashion) to both cables at the bows, the other ends of the ropes on which there is plenty of slack being wound several times

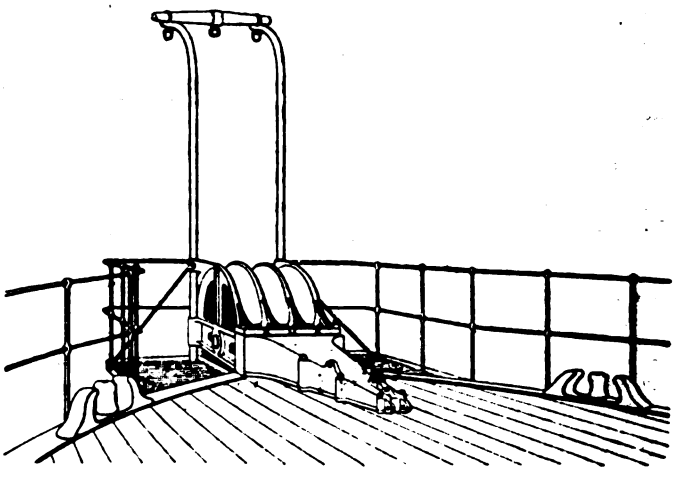

FIG. 68.—Isaac's Triple Bow Sheaves.

round the bullards on deck. These ropes are afterwards used for lowering the splice overboard. In addition to the above the ordinary stoppers are also put on as a matter of precaution, and, this being done, the drums are both slacked away until all strain is taken by the ropes and stoppers, but principally by the ropes. The ship's cable is then cut at a suitable distance for making splice, and the two ends are then at liberty for joining together on deck.

Before dealing with the final splice and completion of the repair, attention may be drawn to the use of a recently adopted

Digitized by Google

form of bow, sheaves. It is handy at times to have three sheaves available, one for an extra line from ship as in lowering a splice, and considering the superiority of cast steel in this class of machinery it is not surprising that every opportunity of economising space and weight by its use should be taken. The triple bow sheaves, illustrated in Figs. 67 and 68, have been designed by Mr. Percy L. Isaac for the Eastern Telegraph Company, and are now supplanting the older forms in this Company's ships. The whole is fitted in a cast-steel frame bolted to the deck girders, and takes up less room and is lighter for the same strength than the original double sheaves in iron. The "Electra" was fitted with these sheaves at the time she was built, and the illustration in Fig. 68 is a deck view of the sheaves as fitted to this vessel, while Fig. 67 represents the bows of the "John Pender," also fitted recently with these sheaves. On the latter vessel the new set weighed 4 tons 9 cwt., as against 7 tons 5 cwt., the weight of the original double sheaves which they replaced. It would be, however, a great advantage if what are known as the "whiskers" or cheeks between the sheaves were retained in the new form. The use of these is to prevent the grapnel rope jumping over to the next sheave when pulled sideways by the strain below.

(To be continued.)

GEARING.

BY E. TREMLETT CARTER.

(Continued from page 515.)

Flywheels.

Although not actually part of the gearing between an engine and the machinery driven, yet a flywheel plays so important a part in the distribution of the strains to which the gearing will be subjected, and is designed so much from considerations of the gearing, that it is thought well to devote a section of this series to a discussion of the questions which determine the dimensions of a flywheel.

Whenever the effort exerted by an engine is not equal to the resistance opposed by the moving parts, both being measured at the same radius from the centre of motion, a change of speed takes place. If the torque exerted exceeds the torsional resistance to motion, the rate at which energy is developed is greater than the rate at which it is taken off by the machinery, and a rise of speed occurs; if, on the other hand, it is less than the opposing torque, energy is being taken off at a faster rate than it is being developed, and the deficit has to be made up by the mass of moving machinery, with a consequent fall in speed. In the case of a steam or gas engine driving a dynamo, the fluctuation of energy in the moving parts is entirely due to changes in the effort; the resistance is practically constant. Now, in order that the fluctuation of energy may not strain the gearing, it will be necessary to absorb it, as it were, before it gets to the gearing; that is, a sort of store or bank for the energy must be set up close to the source of fluctuation, into which the fluctuating energy may surge in and out again, keeping the rate of supply to the gearing constant.

The energy which any rotating mass will hold or store depends on its moment of inertia and on the speed at which it may be run; so that the fluctuation of speed for any given amount of energy entering or leaving the mass will vary inversely with the moment of inertia. In the case of a steam-engine, where there is a large amount of fluctuating energy, if it is desired to limit the change of speed to a low figure, it will be necessary to have a large moment of inertia in the crank. The ordinary crank details have not enough inertia, so that the amount required is obtained by keying a heavy wheel to the crank-shaft. In Fig. 11, let the axis ox represent angular movement of the crank, and the axis oy represent on curve E the varying effort exerted by the engine on the crank measured in moments of that effort about the crank shaft centre, and on curve R R the uniform resisting torque. The latter curve is, therefore, the mean ordinate of the former, since each incloses an area which represents the same energy. At the points a and b the effort equals the resistance, but between them the former is in excess, while on either side the latter is in excess. During the first period, from a to b, energy is being absorbed, and the speed comes to a maximum at b; during the period from b to a, energy is being given out by the flywheel, and the speed comes to a minimum at a. The shaded area above the mean line consequently represents the difference in the energy of the moving parts between the conditions of maximum and minimum speed; that is, the fluctuating energy of one cycle of the crank-shaft.

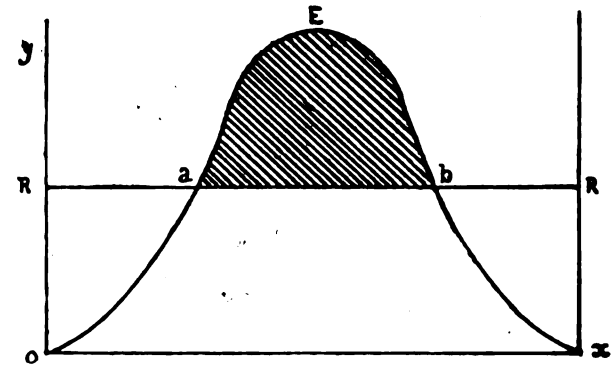

FIG. 11.

Let I represent the moment of inertia of the moving parts, and ω their angular velocity at any instant, measured in radians per second, then the energy of those parts is

$$E = \tfrac{1}{2} . I \omega^2, \quad \text{. . foot pounds.}$$

And since the angular velocity may be expressed in terms of revolutions per minute,

$$E = \frac{\pi^2 . N^2 . I}{1800}.$$

Let ΔE be the fluctuation of energy in foot pounds, N_1 the lowest and N_2 the highest speed during any one revolution; and let N_0 be the normal speed in revolutions per minute.

Then, if I is the moment of inertia,

$$\Delta E = \frac{\pi^2 I}{1800}\left(N_2^2 - N_1^2\right),$$

and,

$$I = \frac{1800 . \Delta E}{\pi^2 (N_2^2 - N_1^2)},$$

whence, in order that the difference between N_1 and N_2 may be small, I must be large. Let p be the percentage variation of speed, then,

$$p = 100\left(\frac{N_2 - N_1}{N_0}\right),$$

and,

$$\frac{N_2 + N_1}{2} = N_0,$$

therefore,

$$I = \frac{90000\ \Delta E}{\pi^2 N_0^2 . p},$$

Engine flywheel rims are usually of cast iron, having a density of 450lb. per cubic foot, and are rectangular in section. If D is the outer and d the inner diameter and w the width of the rim, in feet, then the mass of the rim is—

$$M = \frac{450\, w . \pi (D^2 - d^2)}{4 . g} = 11{\cdot}05\, w (D^2 - d^2).$$

Neglecting the arms, as is usually done, the moment of inertia of the flywheel is—

$$I = M . \frac{D^2 + d^2}{8} = 1{\cdot}38 (D^4 - d^4)\, w,$$

whence, for cast-iron flywheels—

$$(D^4 - d^4)\, w = 6250 . \frac{\Delta E}{p . N_0^2},$$

from which the dimensions of the flywheel rim may be conveniently proportioned. The outer diameter must be chosen with a view to convenience of size and lightness. The larger the flywheel the lighter will be the rim for the same steadying power. It must, however, be remembered that a cast-iron rim should never be run at a greater velocity at the extreme edge

Digitized by Google

than 100ft. per second, while 80ft. per second is the usual limit in practice. At higher speeds the centrifugal stress on the metal is liable to cause fracture of the rim. Where the flywheel is also used as a pulley the diameter is determined by the velocity at which the belt or ropes will be run. Belts are not usually run at higher velocities than 3,000ft. per minute, and are often run at lower speeds than this, while ropes are most economical if run at 5,000.

The percentage fluctuation of speed which will be permitted must be settled by considerations of the class of work which the engine will have to do. It must in every case be such that the flywheel will be more sensitive than the engine governor. This is necessary in order that the governor may not oscillate with the fluctuation of speed during each revolution of the engine; a behaviour on the part of the governor which would be satisfactory enough if it did not lag behind that fluctuation in giving steam to the engine, but which, in practice, causes unsteadiness, owing to the existence of such a lag. In electric light engines the percentage fluctuation should not exceed 1 per cent., while in many cases it is less than $\frac{1}{4}$ per cent. Arc lights show distinctly any fluctuation exceeding 2 per cent.; while glow lamps are much more sensitive to variation of speed. When the engine is coupled direct to the spindle of the dynamo, the rotating parts of the machine will act, in some measure, as a flywheel. If these parts are of solid metal, as in the Mordey alternators, there is no injury done by reducing the size of the engine flywheel in proportion to the moment of inertia due to the machine; but if the parts are copper coils they will be liable to severe strains and to become detached if any such dependence on their inertia is made. Where intermediate gearing is used, the moment of inertia of the machine must *never* be taken into account in designing the flywheel.

The fluctuation of energy in the flywheel of a steam engine, when the torsional resistance is constant, depends upon the distribution of steam during the stroke, on the number of cylinders and arrangement of the cranks, and on the speed and power of the engine. A slight influence is also due to the obliquity of the connecting rod, which should be taken into account if that rod is less than five times the length of the crank; it is, however, usually neglected.

In order to determine ΔE, it will be necessary to ascertain the variation of thrust on the piston rod throughout each stroke. This thrust, at any instant, is equal to the effective pressure of the steam on the whole piston *minus* the inertia of the reciprocating parts. Calling F this thrust in pounds, p_e the effective pressure per sq. in., A the piston area in sq. ins. w the weight of the piston, piston rod, cross-head and connecting rod, in pounds, and a the acceleration of the piston in feet per second. Then

$$F = p_e . A - \frac{w . a}{g}$$

the values of a are + during the first half of the stroke and − during the last half. Thus, the reciprocating parts reduce the thrust in the former and increase it in the latter half; causing a more equable distribution of power throughout the stroke.

Taking the motion of the piston as a simple harmonic motion, to which it very closely approximates, we have

$$a = \left(\frac{\pi N_0}{30}\right)^2 . r . \cos\phi,$$

where r is the radius in feet, and ϕ is the inclination of the crank. The maximum value of this is

$$a\,(\max) = r\left(\frac{\pi N_0}{30}\right)^2;$$

whence the maximum inertia resistance of the piston and reciprocating parts is

$$f_{max} = \frac{w . r}{g} . \left(\frac{\pi N_0}{30}\right)^2.$$

In Fig. 12 the curves f and b represent the front and back indicator diagrams of the steam engine, which is to be fitted with a flywheel. The diagrams should be taken at the conditions of maximum fluctuation (*vide infra*). The intercepts of the ordinates, &c., give the effective pressures along the stroke at various equally distant points. These are plotted below in curve (c), the base being, as before, the stroke of the piston. From this must be deducted the reaction of the moving parts, as given in the above equations. If the ordinates, &c., represent pressures per square inch, the quantity f_{max} must be divided by the piston area before deducting this reaction. The deduction is made as follows:—The quantity f_{max} per square inch of piston area is set up vertically at the origin or left side of the base line, and vertically downwards at the extreme right end. A line joining these points gives the curve of inertia reactions, as shown in Figs. 12 and 13. Taking the algebraic difference

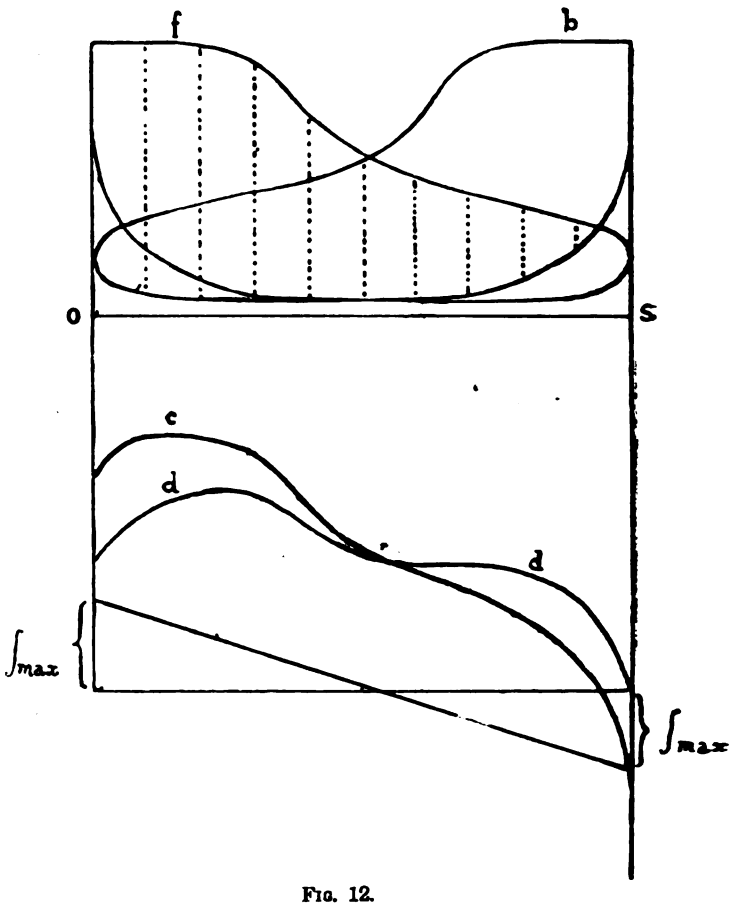

Fig. 12.

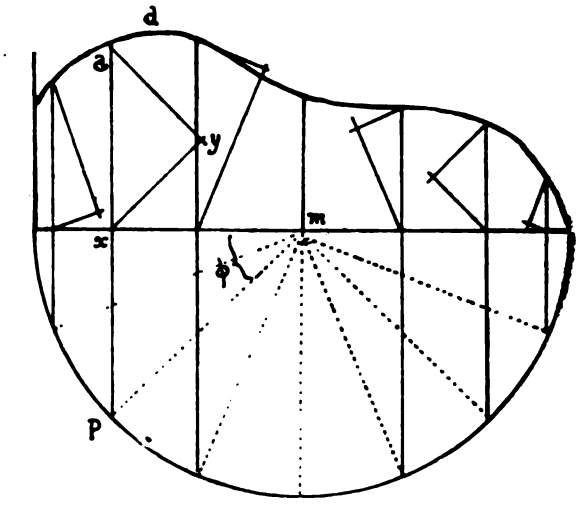

Fig. 13.

between curve (c) and this curve of inertia, we obtain curve (d), the curve of effective thrust on the piston rod. The ordinates of this curve (d) multiplied by the sines of the crank angle to which they respectively correspond would give the ordinates of crank-effort. But the base line of the curve (d) is not one in which equal parts represent equal crank angles, so that it will

Digitized by Google

be necessary not only to multiply the ordinates of (d) by the sines of the angles, but also to set off these new ordinates on a new base of which equal parts shall represent equal motions of the crank. To do this graphically, and without the labour of multiplying by the sines of the several angles, the writer has devised the following modification of the usual method:—On the base of the curve d, Fig. 13, construct a semicircle, and divide its circumference into any number of equal parts. In the figure there are eight parts. From these points draw radii to the centre of the circle, and verticals, such as Pa, to the curve d, cutting the base at x. Take the points on the circle in succession and proceed as will be illustrated by taking the point P. We draw through the point x, where the vertical intersects the base, a line, xy, parallel to the radius Pm, and drop ay a normal to this line from the corresponding point on the curve d. The length of the parallel which this normal marks off, from the point x, gives the value of the crank effort when the crank is at the angle ϕ. It will be seen that the operation has merely consisted in graphically multiplying the ordinate ax of the curve d by the sine of ϕ, giving xy as the required crank effort. The operation is repeated for each of the points on the semicircle, and the successive values plotted on a new base at equal distances apart. The new curve which is thus formed is shown in Fig. 14, the ordinates are the values of the crank effort, and the abscissæ are the amounts of crank angle, reckoned from the position at which the crank is on a dead centre. The curve is, therefore, a curve of work; it represents, if its ordinates are taken on the proper scale, the varying work done on the crank pin during one half revolution. It is unnecessary to determine the value of the scale to which this curve has been drawn, and the operation of doing so would be tedious.

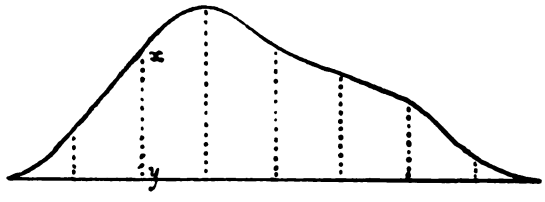

Fig. 14.

We only require to know in what proportion the fluctuation of energy stands to the work done per stroke; and this can be ascertained by means of this curve. Drawing the mean ordinate line, we find a portion of the curve passes above it. The ratio of the area of this portion, above the mean line, to the total area of the curve is equal to the ratio of the fluctuating energy to the work done by the engine in each stroke. If we know the horse-power and speed of the engine, the calculation of this latter is, of course, very simple. The areas may be obtained by a planimeter, or by counting the squares on the squared paper on which the curve should be drawn.

It will readily be seen that, in a single cylinder engine, the position of the points a and b, and the area of the hump above the mean line, will depend on the point of cut-off of steam and on the amounts of back-pressure and compression during the return stroke. In general, the later the cut-off of steam the greater will be the amount of fluctuation of energy; but, after examining a large number of diagrams from actual engines, as well as curves plotted from theory, the writer has come to the conclusion that this rule may be seriously departed from, and that it is impossible to determine any set of coefficients which shall suit every type of single cylinder engine. In some engines the maximum fluctuation was found to occur at a cut-off at half stroke, while others gave an increasing fluctuation as the admission was increased up to full stroke. With compound engines having their cranks set at 90deg., or triple engines with cranks at 120deg., the variation in the amount of fluctuating energy follows a different law; for the earlier the cut-off of steam, below that for which the cylinders are balanced to have equal loads, the greater the fluctuation; and the later the cut-off beyond this point the greater the fluctuation also. This is due to the fact that compound or triple expansions which equally divide the load at a given cut-off will have unequal loads if that cut-off is either increased or diminished. Into the balancing of compound engines and the determination of the fluctuating energy, it is impossible here to enter, as it would take us too far from the subject of gearing. Enough has already been written to show how, from the size of the engine, its speed, and the distribution of steam in its cylinders, the load diagram for each revolution can be obtained.

We turn, in conclusion, to the opposite case which may occur in the design of a flywheel, viz., that in which the effort is constant and the resistance variable. This is the case which meets the engineer when he puts an electro-motor on to certain kinds of work, such as running machine tools. The principle of the calculation is precisely the same as in the case which has already been considered. We must plot the curves of effort and resistance throughout one whole cycle of their changes, drawing the base line on a scale of equal lengths to equal spaces acted through by the forces. We must make a similar calculation of the fluctuating energy, and from this determine the required moment of inertia of the flywheel, finally designing a wheel which shall have this moment of inertia. An example of this may help to elucidate the chief points before we pass on to consider the stresses to which a flywheel is subjected, and the way to deal with them.

Example.—An electro-motor running at 400 revolutions per minute is geared to a machine which is required to run at 100 revolutions. The maximum horse-power to be developed by the motor is 10, and the effort of the motor is constant; but the resisting torque of the machine spindle is 50 per cent. above the mean for the first half revolution of the machine spindle, and 50 per cent. below the mean during the other half revolution. The speed of the machine spindle is required to fluctuate not more than 5 per cent. Design the flywheel, which is to be of cast iron. Following the rule that it is best to place the flywheel as near the source of fluctuation as possible, we shall decide to key it to the machine spindle. It is true that this will involve the gearing in a little heavier strain during starting, but this objection is inferior to the continuous and heavy changes in strain which would result from putting the flywheel on the motor spindle. A little resistance (electrical) in the motor circuit would enable a smooth and easy start to be made.

The mean torque exerted on the machine spindle is—

$$T = \frac{33000 \cdot H.P.}{2\pi N} = 525(\text{lbs.} \times \text{ft.}),$$

whence the maximum torque is—

$$T = 525 + \frac{525}{2} = 788.$$

The difference between these represents the unbalanced torque on the flywheel during the first half revolution or π radians. This difference multiplied by the π radians gives the energy put into the flywheel on account of the fluctuation of speed.

$$\Delta E = (788 - 525)\,\pi = 825 \text{ft. lbs.}$$

From this we calculate the moment of inertia which the flywheel must have—

$$I = \frac{90000 \cdot \Delta E}{\pi^2 N^2 p} = 150 \text{ (gravitation units).}$$

Finding this to be a rather small amount, we can decide to put a disc flywheel on the spindle. Cast iron weighs 450lbs. per cu. ft.; and, if we make the diameter of a cast iron disc wheel equal to 4ft., the requisite thickness will be about 5¼ins.—

$$I = M \cdot \frac{d^2}{8} = \left(\frac{\pi d^2}{4} \cdot \frac{450w}{g} \cdot\right) \cdot \frac{d^2}{8} = 150.$$

If $d = 4$,

then $w = 5\frac{1}{4}$ins. approx.

[*Erratum.*—In the formula for horse-power, on p. 512, *The Electrician*, September 9th, for η read π.]

THE ACTION OF ELECTRIC DISCHARGE ON GASES AND VAPOURS.*

BY C. LUDEKING, PH.D.

I have during the past year made a number of experiments on the action of the electric discharge, as furnished by a Ruhmkorff coil, on gases and vapours of various substances for the purpose of establishing, if possible, whether or not electrolysis takes place. There is a qualitative difference in the products of decomposition that collect at the poles, so far as experiment enables us to determine.

The apparatus that I used in the examination of water-vapour was suggested by Prof. E. Widemann, of Erlangen, and may be briefly described as follows:—

A flask, A (Fig. 1), capable of holding nearly 1½ litres, is filled up to the neck with distilled water that has been boiled for 15 minutes immediately previous to the experiment. It is furnished with a singly perforated good cork, carrying a large tube of 8mm. internal diameter, which serves to conduct the vapour from the flask into the sparking-tube C; this tube is also 8mm. in internal diameter. The two delivery tubes passing from it are 60mm. apart. The vapour coming from the flask A divides, in tube C, into two currents, which pass out by the delivery tubes. The electrodes consist of copper wire 3½mm. thick; they have flat polished ends, and are inserted into the tube C gas-tight by means of rubber stoppers, an arrangement that permits of their being set at various distances from one another. They are placed in such positions that they are located in currents of vapour travelling in opposite directions, as will be easily understood. By this means it is possible to ascertain whether or not there is a difference in the gases separated out at the poles, for these may be collected and analysed. The entire sparking tube is encased in an air bath capable of being heated above 100°C., and thus preventing any condensation. The delivery tubes are firmly clamped and held in position with their ends exactly on the same

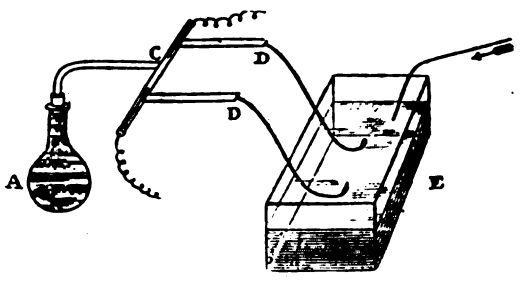

FIG. 1.

level. This is effected by boiling the contents of the flask when only about three-fourths full of water, and collecting the gases given off at once. If the tubes have their ends exactly on the same level, the volumes of gas delivered from each will be equal to one another. By repeated trial it is possible to accomplish this within limits entirely satisfactory. The water in the trough E is maintained at 90°C. or upwards by means of a current of steam, in order to reduce the error resulting from the different solubilities of oxygen and hydrogen as much as possible.

Each experiment lasted from three to four hours, during which time a constant current of steam was given off from the flask and was subjected to the action of the electric discharge, leaping over various intervals between the electrodes. As electromotive power four Grove cells of Browning's make were used. The Ruhmkorff coil was used without condenser, and by its construction could give only a feeble extra current, because the section of the inducing wire was very large and its length very small in comparison with the induced wire. A Geissler tube inserted to remove the extra-current spark did not in any way alter the results obtained, thus substantiating my anticipations; consequently it was unnecessary to resort to the usual means of throwing out the extra-current spark.

When passing the spark at the beginning of an experiment, while there is still air in the apparatus, it is surprising to notice how, in proportion as this is expelled and the atmosphere becomes more and more one of pure vapour of water, the resistance to the passage of the spark increases. It would seem that, just as pure water is a very good insulator, so also pure water-vapour offers very great resistance; in fact, it is possible to obtain sparks three times as long in air as in pure aqueous vapour.

At the conclusion of each experiment the gases were transferred to a eudiometer, and analysed in very much the same way as that used by Perrot (*Ann. de Chim. et de Phys.*, Vol. XLI., p. 161, 1861). This savant conducted a great number of experiments on the electrolysis of aqueous vapour, extending his work over years of time.

In the light of modern theories concerning the cause of electrolytic decomposition, as enunciated especially by Arrhenius, it seemed desirable that these experiments should be repeated. Without entering into detail, I think it will be only necessary to give the results of one of my experiments, which I consider very successful, and which differs from the rest only in better quantitative results, all being alike qualitatively.

In the experiment alluded to, after removal of the hydrogen and oxygen present in proportion necessary to form water, the residues were found to consist of excess of hydrogen—2·6 cubic cm. in the one tube, corresponding to the negative pole; and excess of oxygen, 1·7 cubic cm. in the other, corresponding to the positive pole. From the arrangement of the experiment it is clear that the temperatures of the electrodes must have been the same and constant, *i.e.*, 100° C.

After having assured myself that the above differences in the products of decomposition of aqueous vapour by the electric discharge exist, I experimented next on hydriodic-acid gas, dried, and passed through the same apparatus. It was found that in this instance the decomposition took place very readily, and the positive pole became rapidly covered with iodine, while the negative pole presented a perfectly bright surface of copper. One of the products of decomposition being a solid it was not attempted, of course, to collect the gaseous product. On reversing the current, the poles remaining in the same position and having been previously cleaned, the same phenomenon was again observed, the iodine appearing only on the positive pole. The temperature of sparking was that of the room. But a few minutes were necessary to show the deposition of iodine. By this experiment, in fact, it is remarkably easy to show the distinctive action of the poles in decomposing vapours to a large audience. It is only necessary to fill a large flask having two tubulures, of the accompanying form, Fig. 2 for example, to be found in any chemical laboratory, with dry hydriodic-acid vapour, and then to pass the discharge for, say, fifteen minutes. The electrodes may then be removed and passed round. The proof is thus convincingly furnished that vapours are capable of polar decomposition. When the spark passes through the hydriodic-acid vapour, a great part of the decomposition is of course due to thermal dissociation, and a cloud of iodine vapour rises from between the electrodes at each discharge,

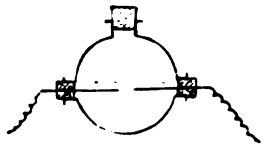

FIG. 2.

rendering this phenomenon very apparent. It is hardly possible to separate perfectly the two modes of decomposition that evidently have place here, nor to understand how they exist side by side.

J. J. Thomson (*Phil. Mag.* [5] XXIX., pp. 358 and 441, 1890) finds that hydriodic-acid vapour is an excellent conductor of electricity. He experimented by passing the vapours of his substances through a platinum tube heated to a yellow heat, and having in it platinum electrodes. It is not impossible that we have here in part a true electrolytic decomposition, and that in amount it is in direct proportion to the conducting power. A pure gas is, I think, not electrolytically decomposed on the passage of the first spark, and is practically a non-conductor. However, by the passage of the first spark there is produced by thermal dissociation a mixture of gases in the pathway of the discharge. This it is that conducts fairly well, so that then electrolysis may take place. The conduction of the current is, therefore, not simultaneous with the passage of the spark, and takes place only during a short time. Consequently, the electrolytic and thermal dissociations are not simultaneous. The partial pressures of the substances electrolysed would thus be reduced; another factor in the promotion of electrolytic conduction.

This may be proved experimentally:—By taking a mixture of the original gas and its components it is possible to effect an electrolytic decomposition by means of the Ruhmkorff coil without the passage of any spark. Such a mixture was prepared, and the electrodes so adjusted that no spark could pass. Then what seems to be an electrolysis was effected, iodine being deposited on the positive pole. That this iodine was not free iodine of the mixture was proved by leaving it out entirely, and making instead a mixture of hydrochloric acid, hydriodic acid, and hydrogen. Then the same phenomenon was observed. We are therefore justified in the conclusion, arrived at also by E. Wiedemann and J. J. Thomson, that the decomposition is in part a true electrolysis after the manner of a Grotthus chain. At least this is one interpretation we may give for the present.

* From the *Philosophical Magazine*, June, 1892.

We have therefore to do with an imperfect insulator, and the electrostatic energy is gradually transferred between the poles. It is necessary that the electromotive force should be sufficient to decompose the chemical compound, as otherwise no decomposition could have place, but only conduction. It would seem, further, that Thomson's view is correct—that the ease of decomposition of the molecule into atoms is proportional to the conducting power. In that gases at ordinary temperatures are such very poor conductors, it would seem that the conductivity is, as I stated above, the result of dissociation by the discharge and the consequent diminution of pressure. I do not think, with Thomson, that the molecules cannot, while the atoms can conduct. I think I have shown that while pure hydriodic-acid vapour does not conduct to any appreciable extent at ordinary temperatures when pure and dry, it does conduct when diluted with any diluent. Further, that electrolysis of vapours is only possible to any appreciable extent when the mechanical action of the spark has caused such dilution of the pure substance beforehand by dissociating it in part.

Further, I made an extended series of experiments on the action of the electric discharge on the following gases and vapours, viz., carbon tetrachloride, chloroform, carbon disulphide, silicon tetrafluoride, marsh gas, olefiant gas, and coal gas. Where one of the products of decomposition is a solid, it is for obvious reasons not possible to use the apparatus above described to show a polar distribution of the products of decomposition. Now all these substances furnish solid deposits excepting silicon tetrafluoride, which was not decomposed. The hydrocarbons yield deposits of carbon, and therefore it was impossible to find a difference in the gases furnished by our apparatus. However, a remarkable fact was observed, which I believe speaks strongly in favour of actual electrolysis, in the case of hydrocarbons especially. It is that the deposit of carbon for these latter always grew out from the positive pole in a way that would indicate its having been separated out at that pole and not mechanically projected against it. The experiment is most conveniently made with coal-gas, and the sparking done in a cylinder over mercury. The carbon grows from the positive pole in form of a very fine filament, very hard and very brittle, and possessing most excellent conducting power. The film is very thin, indeed thinner, than a horse-hair. On examining it under the microscope it is found to be toothed in a very regular way, the teeth being sharp cones projecting towards the negative pole. Ths deposit could not possibly have been formed by mechanical projection of the carbon. From its character the carbon has not been carried to the pole and deposited there, but is, it seems to me, a true electrolytic separation. In any other way than this it would be difficult to explain the dendritic forms. Another thing that speaks against the mechanical projection supposition is that the filament is a mere slender thread. These forms have the greatest likeness to, and remind one very much of, the dendritic forms of metals that grow out from one pole in electrolysis of metallic solutions, and the current in that case seems to act just in the same way as in the gas. Finally, when a slip of stiff writing paper is placed between the two poles, one does not observe, on passing the discharge, a blackening of the side of the paper turned towards the negative pole, which would certainly be the case were the carbon deposited by projection on the positive pole. There is, however, some carbon, in the form of soot that can be easily wiped off, deposited on the negative pole, though only in small amount. This deposit is entirely different from that on the positive pole both in quantity and quality, and I believe it is a true projection-deposit. Consequently the action of the electric discharge on this gas is not simple, but, as might be inferred, almost *à priori*, of complex character. Firstly and chiefly, we have an electrolytic decomposition by virtue of which the carbon is deposited in a well-conducting form on the positive pole ; and, secondly, we have the dissociation due to the heat of the discharge alone, which in quantity is by far inferior to the former. By the heat of dissociation molecules of carbon are set free and are attracted by both the poles by virtue of their constant static charges.

Concerning the hydrocarbons examined—olefiant gas, marsh-gas, and coal-gas—there is no noticeable difference, qualitatively at least, in the action of the discharge, so that they need not be separately considered. The deposition of carbon takes place more rapidly in proportion as the gas contains a higher percentage of carbon ; thus, under the same conditions in the same length of time, more carbon is deposited from olefiant gas than from marsh-gas. The volumes of the two gases begin to increase rapidly at once on sparking, and very soon double the volume of the original is reached, so that the decomposition is no doubt perfect. This result seems anomalous, when we call to mind that acetylene is formed by the passage of the discharge between electrodes of carbon in an atmosphere of hydrogen. We are forced to the inevitable conclusion, which is rather interesting, that acetylene is not formed when only one of the electrodes is carbon, and that it is necessary that both the electrodes be carbon in order that it be formed. Further, we must infer that it is very probable that acetylene is itself decomposed entirely when the two electrodes are metals or when only one of them is carbon. The increment in volume when marsh-gas and olefiant gas are subjected to the electric discharge is so rapid and striking that it can readily be demonstrated to a large audience in lecture. The carbon separated out from each of these gases is the same in kind and form. Filaments 6 to 8mm. long can be readily obtained in a few minutes, and on continuing the discharge they finally connect the two poles, when the spark ceases. The growth of the filament is entirely avoided by frequently reversing the current.

By the action of the electric discharge on vapour of chloroform no carbon filaments are formed, and chemically the decomposition is not simple in character. There is a large amount of gas formed consisting of chlorine (iodised starch-paper is blued) and hydrochloric acid (the gas is rapidly absorbed in part by water, and the aqueous solution is strongly acid), while a dark red liquid is observed on the mercury of the eudiometer due to the solution of one of the products of decomposition in excess of the chloroform. A further examination of this was not attempted. An exact measurement of the increment in volume of vapour was out of the question, owing to the action of the chlorine formed on the mercury of the eudiometer.

Carbon tetrachloride is decomposed very slowly indeed by the discharge. As in case of chloroform, so here also no carbon filament is formed, while the rate of decomposition is entirely different from that of chloroform. A voluminous yellow deposit is observed on the walls of the eudiometer around the negative pole, and chlorine is set free, as appears by the starch test. The gaseous products of decomposition are not rapidly absorbed by water, as was the case with chloroform. A black deposit is observed on the surface of the mercury. Unquestionably, therefore, it follows from all this that the decomposition of carbon tetrachloride by the electric discharge is by no means simple in character.

When the electric discharge acts upon the vapour of carbon disulphide the volume diminishes rapidly. The vapour of this substance offers an enormous resistance to the passage of the discharge. When the poles are only 1mm. apart only very few sparks pass through, the discharge taking its course outside round the eudiometer through the air, a distance twenty to thirty times as great, a proof that the vapour of carbon disulphide is an almost perfect insulator. In the course of the discharge a grey-blue smoke is observed, which gradually pervades the entire volume of the vapour. Here, then, we have no noticeable evidence of electrolysis taking place. The phenomenon seems to be a heat-dissociation pure and simple. There is deposited on both the poles, not the black conducting modification of carbon as in the case of marsh-gas, &c., but a grey non-conducting matter around which the discharge leaps as it passes from wire to wire. The appearance of the same character and quantity of deposit on each of the poles is, to my mind, conclusive evidence that we have to do here, not with an electrolysis, but with a heat-dissociation alone. I should make it a cardinal requirement for a phenomenon of this kind that the deposits on the poles be symmetrical and of equal amounts. By the heat-dissociation the molecules of carbon are liberated along the entire course of the discharge, and are, as the static charges of the poles are equal, attracted simply in one half of the field to the one pole and in the other half to the other pole. The sulphur molecules liberated at the same time are, on account of the great heat, not deposited on the poles. Indeed in this decomposition, a yellow-brown mass is deposited on the sides of the tube which is nothing else than the sulphur condensed there.

Silicon tetrachloride does not appear to be acted on at all by the discharge. Attempts were made to electrolyse the haloid compounds of mercury in form of vapour. The results were all negative, which may, however, be owing to the great difficulties encountered in carrying out the experiments.

It would seem, finally, that some of the phenomena described are true electrolyses in part. Others seem to be "Thermolyses," that is, the compounds are simply dissociated by the heat of the discharge. The predilection of the atoms thus liberated for electricity of different kinds would make them, like pith-balls, fly to the pole having the charge opposite their own, and thus give the entire phenomenon the appearance in all respects of a true electrolysis, while in reality there is the greatest possible difference. It is very difficult to separate the "Thermolysis" from electrolysis in the experiments I have described, and the phenomena indicate that in most cases described they go hand in hand.

The Electrical Industry in the United States.—A paragraph has been going the round of the Press to the effect that, according to a recent estimate, the capital invested in the electrical industry in the United States amounts to £140,000,000. Of this total, £70,000,000 is allocated to light and power, and £20,000,000 to the electrical supply business.

ON THE APPLICATIONS OF ELECTRICITY IN THE ROYAL DOCKYARDS AND NAVY.*

BY HENRY E. DEADMAN.

(Concluded from page 541.)

Torpedo and Gun Circuits.

Torpedo Circuits.—When the Whitehead or fish torpedo was first adopted as an element in the offensive armament of ships of war, it was ejected from its carriage by means of an impulse rod or piston actuated by compressed air. The ejection was effected by opening a communication valve between the impulse cylinder and a reservoir of compressed air. As it was necessary that the discharge of the torpedo should be effected from an observing and directing station remote from the torpedo itself, electricity was early pressed into service for effecting the communication between the observer and the firing valve; and in 1879 an electrical arrangement was first fitted for enabling the firing valve to be opened from a distance. The method of ejecting torpedoes from a carriage by means of an impulse rod was soon abandoned however, and the air-gun principle took its place. By this method the torpedo is itself placed in a tube or gun, into which compressed air is admitted behind the torpedo; and the ejection is effected by the expansive force of the air acting directly upon the rear of the torpedo, exactly as the explosive force of gunpowder drives a shot out of a gun. When worked from a distant point the firing valve was still opened by electricity, but on an improved plan. In the earlier ships the batteries were placed below the water-line, and the circuits were complete with main and return wires. Where not protected by armour or not below the water line, the wires were duplicated and kept apart from each other, as greater security against both circuits being destroyed at one time from the same cause. The circuits now used are earth circuits, and are duplicated where exposed, as for instance near the torpedo tubes. Within the last few years powder impulse has been introduced for discharging torpedoes. For this purpose a cartridge containing a small charge of gunpowder is placed in a powder chamber prepared for it at the rear of the torpedo tube. The cartridge is fired by means of an electric current generated in a local circuit, that is, by a battery secured to the torpedo tube itself. This local circuit is momentarily completed by the action of the firing circuit from the observing station.

Gun Circuits.—Electricity is further employed in the Navy for effecting the discharge of guns, either individually at the gun positions or simultaneously in groups, from some protected observing station. So far as the writer is aware, this system was first practically employed about 1874, and the current was obtained by means of pile batteries. These were formed of about 160 elements, consisting of alternate copper and zinc plates, separated by fearnought (a kind of flannel) dipped in diluted vinegar. With these batteries high-tension fuses were used, which were not only dangerous, but frequently failed owing to the difficulty of keeping the circuits free from moisture. From 1874 down to about 1881 gun circuits were fitted as complete wire circuits. Now earth return circuits are adopted, except in some cases of auxiliary circuits which are still complete wire circuits.

Safety Arrangements.—These are highly necessary in the ordinary working circuit, in view of the possibility of the gun being fired prematurely with possibly disastrous results. For instance, the gun might by mischance be fired before the breech block was properly replaced and locked; and to avoid this danger the circuit is broken automatically by the act of unlocking the breech, and the connection is again made automatically in the act of relocking after loading. Again the gun might be fired after the breech block was secured, but before the gun was run out; in which case the energy of recoil would be expended in smashing up the gun mounting. To avoid this the circuit is automatically broken at the front end of the carriage by the action of recoil, and is remade automatically just as the gun again reaches its run-out position. The making and breaking of the circuits are effected by means of rubbing contacts; and while these give assurance against an accidental discharge of the guns, they are not an unmixed good, as they sometimes cause a miss-fire; and a continuous protected circuit without any of these breaks would be more certain and reliable. In the earlier turret ships, especially in the rigged ones, the guns were masked by portions of the ship's structure at certain angles of training. In such cases devices were introduced for automatically breaking the firing circuit at these particular angles. In all the later turret and barbette ships, the turrets or barbettes are placed near the extremities of the ship; and while having a limited arc of training, they are unobstructed in their fire throughout the whole of this arc when the ship is cleared for action. Consequently there is now no necessity for any safety arrangements. In the modern as in earlier ships the full depression of the guns cannot be obtained throughout the whole horizontal arc of training; and the danger of firing into the deck is obviated by an ingenious automatic arrangement, which is in connection with the hydraulic or other mechanism for workihg the guns, and has nothing to do with the electric circuits.

Electric Communication.

The efficiency and safety of a modern war-ship are largely dependent upon the means of communication between the various working parts of the vessel. The officer directing from the conning bridge the movements of the vessel must have the means of instantly transmitting to the engine-room a few pre-arranged signals with regard to the starting, stopping, &c., of the engines; and he likes to have the signal transmitted back to him to assure him that his order has been correctly received, and is about to be carried out. When manœuvring in squadrons, in which his ship has to keep her correct station in relation to the others, he must be able to communicate to the engine-room his orders regarding small variations of speed, say, one revolution more or less over a considerable range of speed. He also likes to be able to ascertain for himself on the bridge the actual revolutions of the engines; and he prefers to do this at a glance, without having to take the trouble to use a watch and count the revolutions, say, for a minute. Where the steering-wheel is immediately under his own eye, as it generally is when steam or other mechanical power is applied for steering the ship, he likes to have an indication on the bridge that the rudder is properly responding to the motions of the steering wheel. Should either of the alternative steering positions below have to be resorted to, he requires a certain means of communicating his orders to the steersman at that position. In addition to the means of transmitting a few pre-arranged signals, he also requires a means of conversing from the conning bridge with the engine-room, with the steering positions, and with a few other places. In action, when the vessel's movements may be directed from a protected conning station, he needs, in addition to the foregoing requirements, to be put in communication with the officers at the various gun quarters, including turrets or barbettes, and also those at torpedo-discharging positions, &c. In fact he requires to be placed either directly or indirectly in communication with every part of the ship where officers and men are stationed. Where only a few pre-arranged signals are required, these intercommunications are effected by means of transmitting and receiving instruments, either mechanical or electrical; while for communications of a general character voice pipes are employed.

About six years ago many complaints were received from ships as to the unsatisfactory nature of the means of signalling and intercommunication; and as many new instruments, chiefly electrical, were then being proposed for use in the navy, a committee was appointed, consisting of naval officers, naval constructors, and marine engineers, of which the writer was a member, to inquire and report upon the whole subject. In the course of the inquiry the views of a large number of representative naval officers were obtained, in order to determine firstly what intercommunication was necessary and best for a ship of war. On this primary question naval officers were not wholly agreed; but there was sufficient accord to enable a standard method to be laid down. In order to arrive at the best means for effecting these intercommunications, the committee studied all the methods that had been previously tried, including those in use in the mercantile marine. They carefully examined and tested many new instruments that were submitted to their notice, and carried out a number of independent experiments.

Voice Pipes and Call Bells.—Among other means of improvement, the committee recommended that all voice pipes connecting stations where there is noise or vibration, and all others if they are over 100ft. in length, should be increased from 1¼in. internal diameter, the size then in use, to 2in. internal diameter; and that with these larger pipes a system of electrical call-bells should be fitted. This plan is now generally carried out in the navy, and has resulted in greatly improving the means of communication. The call-bell arrangement consists of an ordinary push board at the sending station, with the well-known annunciator or drop-shutter instrument at the receiving station; the dropping-shutter indicates the station from which the call has come, and therefore the particular pipe to be spoken through. It is found that with voice pipes communication to places where there is much vibration or noise is not very satisfactory. Many devices have been and are still being tried with the object of improvement. The committee were much impressed with the immense facilities offered by an electrical system of communication; and amongst other things, telephones of different forms were tried in substitution for voice pipes. The results were not such as to lead to their introduction into the ships of the navy.

Telegraphs.—With regard to instruments, though for ship work a mechanical system has some great advantages over an electrical, yet as a means of establishing communication between these instru-

* Paper read before the Institution of Mechanical Engineers, Portsmouth, July, 1892.

Digitized by Google

ments at distant stations the electrical system is far and away the best. The many disadvantages of a system of shafting and bevel wheels, led through a considerable portion of the length of a ship, scarcely need to be stated; while the great facilities offered by a simple insulated wire are equally self-evident. The committee therefore recommended that the one mechanical telegraph for communicating orders from the bridge or conning tower to the engine-room should be retained, but that the telegraph for orders respecting speed of revolution should be electrical. Many of these electrical telegraphs have been fitted in the navy; but the reports upon them have not been uniformly favourable, although in some instances they have been highly so. Whether the grounds for the unfavourable reports have always been good and sufficient is a matter of opinion; but at the present time electrical telegraphs in the navy appear to be somewhat under a cloud, so that the field is still open for invention in this direction. The telegraphs already in use are worked by primary or secondary batteries; while a new form has been proposed, to be worked direct from the ship's dynamo.

Other Applications of Electricity.

Submarine Mines.—There are some other applications of electricity in the naval service, which may be referred to without any detailed descriptions. One important application is that to submarine mining, whereby stationary torpedoes or mines are exploded by an electrical current from an observing station on shore, after the position of an enemy's ship in relation to the mines has been ascertained by means of range-finding instruments in two observing stations at a considerable distance apart, but electrically connected. An electrical apparatus has also been designed and experimented with for enabling a boat, without any person in it, to be sent from a safe distance into an enemy's mine-field, to explode and thus render harmless the mines laid there. By this apparatus the boat can be steered, the engines stopped or started, and the countermines dropped where desired, and exploded. In this way an otherwise exceedingly risky operation can be performed without danger to life; and the worst casualty that can happen is the loss of the boat only.

Night Signalling.—Electricity is also applied to night signalling. The ordinary semaphore instrument as used by day is illuminated at night by means of incandescent lamps in front of a reflector, the whole being contained in a wooden box placed a short distance in front of the semaphore arms, which are painted white in order to make them more distinctly visible by night in the rays of the electric lamps. Another system of night signalling has lately been introduced, consisting of four flashing lamps placed in a vertical line at topmast head. The lamps are incandescent with special filaments; and one lamp or more can be switched off at will by an arrangement of switches in the chart-house, where there are also four small lamps which follow the movement of the lamps at masthead. By a preconcerted code the combinations of the lamps are interpreted. This arrangement is intended principally for squadron sailing at night, to convey orders as to altering course, speed, &c.

Gun Sights.—The sights for guns are now adapted for night firing by employing electricity for their illumination. This is effected by means of small incandescent lamps, for which the current is obtained from a primary battery consisting of three Leclanché cells in a box secured to some part of the gun mounting. A switch is also fitted for each sight, having a resistance connected with it, so that the current can be varied at will, and thus the lights can be made more or less brilliant to suit the circumstances.

Examination of Gun Bores.—An apparatus is now supplied to ships for examining the bores of guns. It consists of an inclined mirror supported in a metal frame, which is made to fit the bore, and can be pushed into any part of the bore by a long rod screwed into it. According to the size of the gun the frame carries from one to four 100 c.p. lamps, which illuminate the bore; and by the aid of the inclined mirror a close examination can be made for defects.

Motors.—The application of electricity to motors has not yet gone very far, not so far, in fact, as in some other nations it has already gone or is now going. Of the success of the application to the working of guns, supply of ammunition, &c., the writer is not very sanguine; but if results prove satisfactory the Navy will no doubt quickly profit by the experience of other nations. Electrical science is, as yet, in its infancy, and it promises enormous developments in the near future, so that in a few years operations may be performed by electricity which are not dreamt of now. In any case the British navy will not fail to press into its service every development of science which will increase the efficiency of the nation's first line of defence.

DISCUSSION.

The discussion was opened by Mr. W. H. ALLEN, who called attention to the system followed at Portsmouth for testing steam engines used for the production of electricity. He considered that the measurement of the feed water pumped into a large boiler would not afford the means of determining the efficiency of the engine, and advocated the condensing and measurement of the exhaust steam. Less than four years ago a dynamo to meet the Admiralty requirements weighed close on eight tons, but by reason of improvements made the specification could now be filled on a weight of five tons.

Mr. R. E. CROMPTON said the chief thing to be learned from Mr. Deadman's Paper was that our own Admiralty was very much behind in the matter of electricity. For instance, the projector now in use was that of ten years ago. The French had progressed in this matter, but the Germans had gone ahead of them, while England had been stationary. He had brought out a projector which was half the weight of that used in the Royal Navy, and had all its good qualities, with some additions. In place of solid gun-metal arms they used light steel tubes. The hand lamp they had done away with, and one which was not only automatic but which also cost less had been devised. The German carbons were better than those of France, but the Belgians were now coming to the front with carbons that were quite good enough, and were but half the price usually charged. He was sure that Mr. Willans would have supported the last speaker in his strictures as to the manner in which engines were tested. He thought that the whole question of electricity on board warships was unsatisfactory. Power transmission, as well as lighting, ought to be carried out by electrical means. It was possible to lay down a network of mains so that it would be practically impossible to put the installation out of action. He would substitute electricity for hydraulic power and compressed air.

Mr. CORNER, the chief engineer to Portsmouth dockyard, said that the conditions of testing electric light engines were fully known to all contractors who were invited to tender, and though the limit was 32lb. of water to each horse-power, yet 1lb. in excess of this was allowed in order to cover errors of testing.

Mr. W. H. WHITE said he was one of the Whitehall officials, and therefore he supposed he must be expected to move slowly. For his own part, since electricity came forward as a practical factor in warship design, ten or eleven years ago, he had tried to inform himself on all inventions and changes which had borne any semblance of promise, and he had endeavoured to utilise all advances. Outside the personal question, however, the Admiralty made it a ruling principle to test everything that showed any promise. Mr. Crompton, as an electrician, started with the axiom that electricity was the best for everything. The proposition had, however, been disputed by those whose opinion was certainly worthy of consideration; in fact, the majority of those entitled to speak on the subject with greatest weight most decidedly preferred hydraulics. It was also a serious matter to introduce radical changes in so complex a machine as the Navy. That was a very practical consideration which those who were actually responsible dare not forget. For his own part he had seen a warship in which all operations were performed by electricity, and what he had there learned had not been of a nature to force him to the same conclusion as Mr. Crompton. He had, however, been much struck by the arrangements carried out, and he thought that such a thing might come in the future, but at the present moment the time had not arrived. Some of the officers in the service best acquainted with these matters, those who were connected with the torpedo side, had expressed the greatest doubt as to the advisability of using electricity to the extent advocated by Mr. Crompton. There was one point they must not forget in estimating the respective merits of electricity and the other means of transmitting power. That was the question of fuel consumption, always a vital point on shipboard.

A BELGIAN 500 HORSE-POWER DYNAMO.

We are indebted to *L'Électricien* for the following particulars relating to a 500 H.P. generator which has recently been built by the Société Internationale d'Électricité of Liège for La Fabrique d'Armes de Herstal, where the current is employed mainly for motive purposes.

The dynamo is a shunt-wound Gramme-ring, multipolar machine, coupled direct to a compound condensing engine by Van den Kerchove, which runs at 166 revolutions. The field-magnet system forms a crown, and consists of 10 sections bolted together. There are 20 poles, and 6mm. clearance is allowed. The sections of the field-maguet system complete with their coils were first assembled, and then pulled to pieces again, to leave space for the building of the armature, the huge proportions of which necessitated its construction *in situ*. The method of constructing the armature was as follows:—A hub was keyed on to the shaft under hydraulic pressure, two cast-iron cheeks being then put on; the periphery of these cheeks being notched with 100 indentations. The diameter of the armature is 4·8m. (15·8ft.). The core is composed of iron sheets 7mm. (27·5mils.) thick, insulated from each other by paper, the total length being 40cm. (16in.), and the depth being 13cm. (5·2in). The core discs are not only kept in place by pressure, but are traversed by bolts and cross-pieces to the number of 50 each.

The armature conductors are composed of copper strips 4 × 5mm., insulated with cotton and shellac. On the external circumference there is only one layer per turn; but inside, in the spaces left by the notches in the discs, the wires are two deep. The total number of turns on the armature is 2,400. There are two commutators, each 2·5m. (8ft. 3in.) in diameter, to which alternate coils are brought. The armature windings are stayed against centri-

Digitized by Google

fugal action by phosphore-bronze hoops, the peripheral speed being 16·75m. per second (3,300ft. per minute). The current is collected by 80 metallic strips, which can all be actuated simultaneously.

The maximum output of the machine is 2,440 amperes at 125 volts. The current density in the armature conductors is 3 amperes per sq. mm. (1,935 per sq. inch), and in the shunt coils 1·6 amperes per sq. mm. (1,032 per sq. inch).

The choice of a metal for the field-magnets was not arrived at until after numerous tests. Wrought iron was too expensive, and cast iron did not present a satisfactory magnetic quality. Extra-soft steel, from the Angleur Steel Works, was finally decided upon; its magnetic permeability was found equal to that of commercial soft iron, and it could be cast.

The weight of the steel shaft is 10 tons, that of the iron of the armature alone 6 tons, and that of the cast-iron discs 8 tons; the weight of copper on the field-magnets is 2 tons, while that on the armature amounts to over half a ton.

ELECTRIC LIGHTING AT HANLEY.

The following is a condensed summary of the contract with the Brush Electrical Engineering Company which has just been entered into by the Hanley Town Council:—

Four Lancashire boilers, each 28ft. by 7ft., to generate steam at a pressure of 140lbs. Five vertical compound condensing engines, three to be of 200 I.H.P., and two of 100 I.H.P., at a steam pressure of 120lb. Five alternators, three to be of 100 units, and two of 50 units, the machines to be driven from the engines by ropes. There is to be a separate vertical engine and dynamos for the exciters, and a separate compound engine for the air and circulating pump and surface condenser. Each alternator, each exciter, and each circuit is to be equipped with complete switchboard. The primary mains are to consist of two lines of cast-iron socket pipes, into each of which a concentric cable will be drawn, these to be run from the generating station on canal side to the compulsory area, together with a third line of cast-iron pipes for future requirements. There is also to be a primary ring main of the same character, embracing five transformer points and fifteen transformers within the compulsory area. The low-tension distributing mains to be laid throughout the streets scheduled in the compulsory area comprise a small cast-iron trough with cast-iron lid, with two separate insulated cables embedded therein in bitumen. Total of this contract, £13,964.

With regard to the street lighting within the compulsory area the contract includes twenty 2,000 n.c.p. Brush direct current arc lamps and posts, one switchboard, and two dynamos, each capable of developing 12,500 watts; two vertical compound steam engines, having cylinders 6in., 10in., and 8in. stroke; 2 miles 640 yards of copper conductor, insulated with vulcanised rubber, and braided and drawn into wrought-iron pipes, with all the necessary fittings, as specified; total, £1,796. Total for general supply and street lighting £15,760.

Abstract of Tenders Received.

The following schemes utilised Canal side for the generating station, where the value of the land is 6s. per square yard, and the distance from compulsory area 840 yards:—

High Tension Continuous Current Plant with Continuous Current Transformers to a Low Tension Distribution in the Compulsory Area.

1. The Electric Construction Corporation (Ltd.), London £21,979

High Tension Alternating Current Plant with Transformers on Customers' Premises.

2. Messrs. C. A. Parsons and Co., Newcastle-on-Tyne .. £19,100

High Tension Alternating Current Plant, with Transformers at Sub-Stations and Low Tension Distribution in the Compulsory Area.

3. *Permission to publish withheld* ....
4. Messrs. J. G. Statter and Co., London £18,517
5. Messrs. J. E. H. Gordon and Co. (Limited), London.. 17,286
6. Laing, Wharton and Down Construction Syndicate (Limited), London 15,690
7. Westinghouse Electric Company (Limited). London.. 14,526
8. Brush Electrical Engineering Co. (Limited) London (accepted) 13,964
9. Messrs. J. D. F. Andrews and Co., London 10,115

The following schemes utilised the land in Percy-street for the generating station. This land is within the compulsory area, and is in the centre of the town, and valued at £3 per square yard. There is no water for condensing, and coal must be carted:—

Low Tension Continuous Current Plant with Accumulators.

10. Messrs. Paterson and Cooper, London £20,500
11. Messrs. Johnson and Phillips, London 19,350
12. Electric Construction Corporation (Limited) 17,514
13. Messrs. Sharp and Kent, London 14,150
14. Messrs. Crompton and Co. (Limited), London 13,000

Low Tension Continuous Current Plant without Accumulators.

15. Messrs. Siemens Bros. and Co. (Limited), London ... £15,430
16. Manchester Edison-Swan Company (Limited)..... 12,140
17. Messrs. Woodhouse and Rawson United (Limited)... 8,750

The following schemes utilised the land adjoining town yard for the generating station. Here the land is valued at 6s. per square yard, and the distance from the compulsory area is 400 yards. There is no water for condensing, and the coal must be carted.

18. Messrs. Siemens Bros. and Co. (low tension) £18,350
19. Messrs. Johnson and Phillips (high tension)..... ..... £17,550

All tenders were for a total output of 400,000 watts, except that of Messrs. Woodhouse and Rawson, which was for 300,000. The horse-power varied from 450 to 800. All the low tension schemes except No. 12 were on the 3-wire system. Nos. 2, 13, 14, 19 specified Willans engines, and Nos. 1, 3, 4, 15, 18 horizontal engines, while No. 2 specified steam turbines coupled direct to alternators. Nos. 1 to 9 were all condensing schemes. No. 9 did not include for transformers.

The tenders invited for street lighting were for 20 arc lamps distributed in the compulsory area. Some tendered for an entirely separate plant, the arc lamps being lighted and extinguished from generating station. Others tendered for alternating current lamps controlled from a transformer station within the area; and some tendered for no separate system at all, but for taking the electricity from the nearest general supply cable, and requiring the lamplighter to go round to light up or extinguish. In each of these classes there were variations, some including both arc lamps and posts, some including lamps but not posts, and others excluding both. No fair comparison could, under these circumstances, be made, and we do not, therefore, publish these tenders.

LEGAL INTELLIGENCE.

Cox, Robinson and Company.

At the Liverpool Bankruptcy Court last week an inquiry was held in this matter. The debtors carried on business at Strand-street, Liverpool, as electrical engineers. The joint statement of affairs showed liabilities £1,627, and assets £873, excluding £42 due to preferential creditors. The sum of £430 was set down as value of patents; £250 stock in trade, and £125 book debts. Their cause of failure was stated to be loss in developing sundry patents. Charles Walter Cox said that the partnership commenced in September, 1887, each partner contributing equally to the stock, working tools, and electrical apparatus, valued at £250. He was to find working capital as required by the business, and between 1887 and 1890 paid in about £800. In 1890 they patented an electric invention for advertising purposes called "The Levonia Flashing Letters," and an agreement was entered into by the Empire Varieties Company, Leicester-square, London, for working a magnetic apparatus in connection with the "show," of which, under agreement, details could not be given. The inquiry was adjourned.

A list of creditors under this failure will be found in our Trade Notes this week.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 9, 1892.

The Boston West End Street Railway.—So much has been written about the gigantic power station of the West End Street Railway in Boston that very little remains to be said. It may be of interest, however, to English readers to know that the first half of this plant—which has been in process of construction for three years—is completed and is now in daily operation. According to the plans which chief engineer Pearson has formulated, the ultimate steam capacity of the plant is to be 26,000 H.P., of which amount 12,000 is now installed. The engines are of the Reynolds-Corliss type, and were built by the E. P. Allis Company, of Milwaukee, and were designed to develop 1,000 H.P. under the most economical conditions, and work up to 2,000 H.P. at a maximum. The guarantee of the builders is that under a load of 1,000 H.P. the steam consumption should not exceed 13 pounds per H.P.H. It is reported that careful tests show that even less than this amount is consumed. The engine cylinders are respectively 23, 36, and 52in. in diameter, and have a 48in. stroke. The steam pressure in the three cylinders is respectively 160, 35, and 5lbs. The speed for which the engines are built is 72 revolutions per minute.

Digitized by Google

Electric Traction at St. Louis.—As indicating the rapidity with which the electric railway industry in this country is growing, it may be stated that the General Electric Company recently booked an order for about 80 car equipments for one of the principal railway lines of St. Louis, Mo. This additional equipment for St. Louis will place the entire street railway system of the city under the electrical system of operation. It is said that the General Electric Company will furnish for this order the Thomson-Houston system of street car motors. An interesting feature of the equipment is the specification that the generators furnished shall be of 800 H.P., these will be by far the largest generators in use in any plant in this country. The type to be used will probably be that now in service in the West End station in Boston, which is a four-pole machine with Gramme ring armature, using four brushes.

The Trolley System in New York.—The advocates of the trolley system still continue to urge its adoption for the street railways of the residence sections of New York, and it is more than likely that before twelve months have passed franchises will be secured by some of the New York companies to operate their horse-car lines by the overhead trolley system.

The Chicago Exhibition.—The only important piece of information regarding the electrical exhibits at the World's Fair which has been given out during the present week is the announcement that the collection of relics, paintings, and other mementoes of the laying of the Atlantic cable, which were bequeathed by Cyrus W. Field to his children will be kept together and placed on exhibition at the World's Fair in 1893. It is said that they will form a part of the Western Union Telegraph Company's exhibit.

CORRESPONDENCE.

THE MAGNETIC BALANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On reading up the latest numbers of *The Electrician* I find a note (Sept. 9) referring to the instrument exhibited at the British Association and criticising the imperfect magnetic contact with the ends of the test sample, out of which an uncertainty is said to arise. To prevent misunderstanding I beg to state that this uncertainty does not affect the principal measurement, viz., that of induction by tractive force (as it would in the "divided-ring" or "permeameter" type) because the motion has been for this very reason transferred to the cheeks of the purely instrumental air-gaps, the invariable configuration of which is secured with great care.

On the other hand the shearing will certainly be somewhat affected by the nature of the contact; however, this only enters as an error, the variations of which I think will be negligeable with reasonably careful end-squarings, since the reluctance of the other instrumental parts is much larger than that of those contacts. I intend to have the balance still further tested, and this point may be easily settled in a few trials, *e.g.*, by interposing thin paper and measuring the effect produced thereby. As a matter of fact I never intended anything more than an approximation to, say, 2 or 3 per cent.; if higher accuracy be aimed at the precept may be given:—Don't be in a hurry, turn an ellipsoid and use a magnetometer.

As regards the railway-buffer contact or the artificial brass-gap you propose, I believe it would be quite as difficult to ensure the reproduction of exactly the same configuration in every case as it now is, so that the uncertainty about the shearing would not be diminished. The instrumental air-gaps are both ½ mm.; I have resisted the temptation to still further reduce them, thereby diminishing the shearing, because the relative effect of any variation of dimensions would increase. And no amount of workmanship could entirely prevent such slight variations occurring through changes of temperature, &c.—Yours, &c., H. E. J. G. DU BOIS.

Physical Institute, Berlin University,
Sept. 19, 1892.

THE KELWAY SYSTEM OF SIGNALLING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The important Article, Semaphore *v.* Morse, in your last week's issue contains a statement respecting the "Kelway" system of signalling which, in justice to myself, requires some explanation. The statement is that "*the only possible advantage of so cumbrous a device is, that it is legible by a perfectly uninitiated person. It was difficult indeed to see what use could be found for it*, but an opportunity was afforded during the recent elections, when the system was used to signal the results to a crowd outside the National Liberal Club." The italics are mine.

The board upon which the incandescent lamps were arranged, exhibited at the Naval Exhibition last year, at the Crystal Palace, and, recently, at the National Liberal Club, was hastily made and did not correctly represent the arrangement devised for actual use in signalling at sea and elsewhere. In practice the lamps will be fixed on a frame composed of metal tubes sufficiently large to carry the wires; the whole presenting to the wind and enemy's fire a considerably smaller superficial area than existing "service" search-lights, even when a six-foot letter is used.

As to the advantages of my system, I venture to claim that the mere fact of the signals being readable by uninitiated persons, as demonstrated to thousands at the above-named places, stamps the invention as one deserving the serious consideration and support of all interested in the important subject of night signalling, as it cannot truthfully be denied that the enormous sums already expended upon signalling have failed to produce satisfactory results in the Navy, as the following cutting from the *Times* of the 30th July last proves:—

"Last night the inhabitants of Penzance were gratified with a display of search-lights by many of the ships, a general order having been given for search-lights to be ready at 10 o'clock. Not a few of the ships interpreted this as a permission to begin working their lights at the hour named without waiting for a further signal from the flagship. They were, therefore, ordered to extinguish their lights and wait for further orders. *The fact that more than an hour elapsed before this cancelling order was received, understood, and executed by some of the ships anchored at a distance from the flagship would seem to point to some deficiency in the signal department of the mobilised and newly-commissioned ships*, about which I shall, perhaps, have something more to say before the manœuvres are over."

Again, on the 9th August last, the same correspondent wrote:—

"In the former letter I mentioned the difficulty experienced by the flagship in getting its signals taken in and answered by some of the ships stationed at a distance. This difficulty has again been more than once experienced since we left Killery Bay, especially in the case of night signals transmitted by means of the flashing lantern. . . . This deficiency in the signalling department is a serious evil in any case, and might in some cases be a fatal one. . . . I am inclined to think from what I have heard and seen that the methods in use at the School of Signalling now established by the Admiralty are too theoretical, and not sufficiently practical. . . . Year by year I have noticed the same faults and listened to the same complaints from officers of the signal department. . . . There seems to be in some quarters a tendency to underrate the importance of rapid and accurate signalling, to suppose that the rating makes the signalman, who has to learn the very rudiments of his practical duties after he has joined his ship."

Your recognition, Sir, of the importance of the subject is evidenced by the space afforded to the article "Semaphore *v.* Morse," and if you will favour me with the insertion of this communication in your influential journal, emphasis may be given to the fact that a simple and reliable system of signalling is available on sea and land.—Yours, &c.,

London, September 21, 1892. C. E. KELWAY.

EARTH-CURRENT STORMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Following up Mr. Preece's Paper on "Earth-Current Storms," recently read by him before the British Association, and his appeal to observers abroad, I willingly send you herewith a few details of my experience in this part of the world during one of the earth-current storms between the 12th and 17th July last, which may perhaps be useful when associated with similar reports from various other stations on or about the same date.

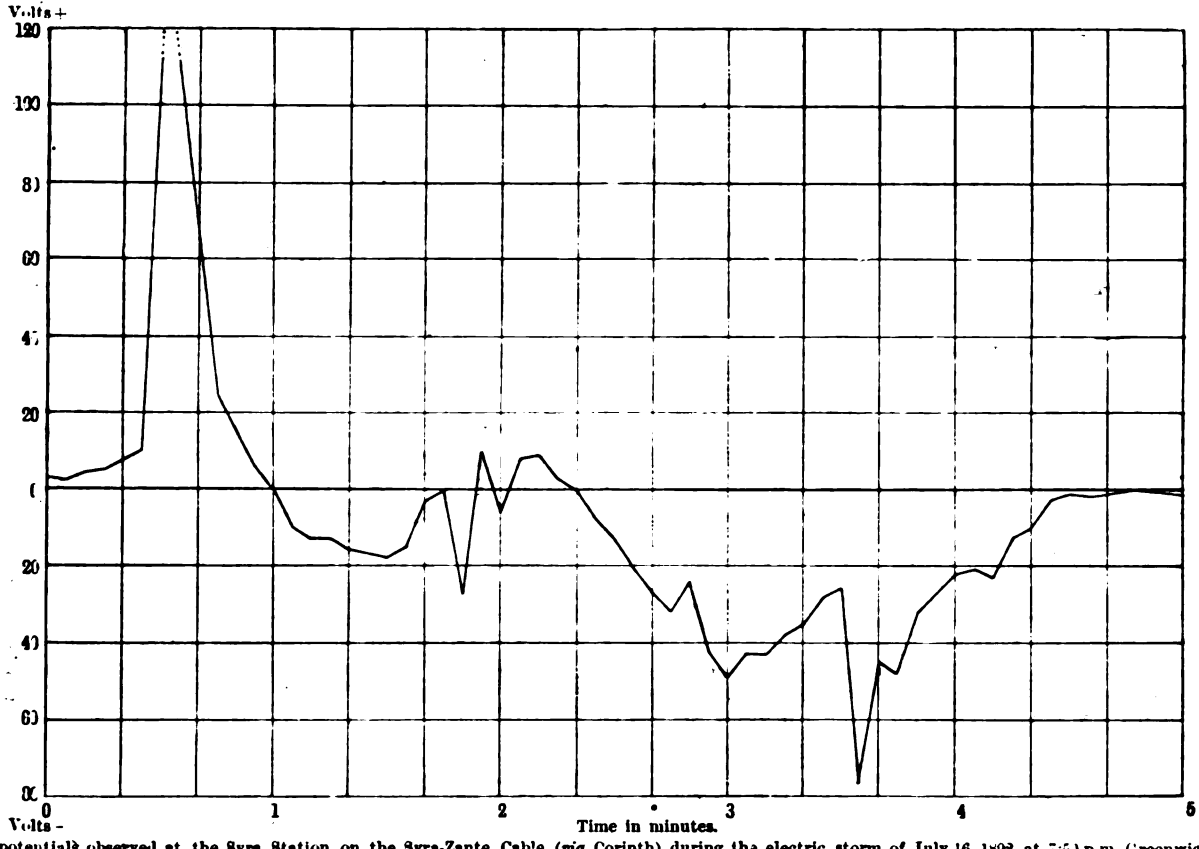
It was at 5:50 p.m. (Greenwich time) on the 12th July we first observed the effect of the abnormal earth currents by the siphons of our recorders being suddenly sent flying off the slip, and the coils remaining deflected for about fifteen minutes, during which period all work was suspended. One of our morse circuits to Smyrna was also rendered unworkable. On this occasion Athens reported a slight shock of earthquake. During the 13th, 14th, and 15th July the earth currents were noticeable, but their intensity was not such as to interrupt the working of any circuit; however, from noon to 8:30 p.m. (Greenwich time) on Saturday, 16th July, we were in a state of confusion, and at times all our circuits were ungovernable, and the traffic suspended in consequence.

As Mr. Preece justly says, at such moments our attention is given to getting off the work and not for experimenting, but at 7:50 p.m., when nothing could possibly be done, and the electric storm appeared to be at its zenith, I took the least important circuit and which seemed to be the most affected, for the purpose of obtaining the observations which are plotted in the accompanying curve. The opposite signs of the potentials were accepted as compared with the position and negative currents of a voltaic battery. It was reported at the time that all the lines in Greece, Italy, and South Russia suffered from the severity of this storm, stopping the traffic all the evening.

On Sunday, 17th July, we were troubled from 11:35 a.m. to 1:30 p.m. (Greenwich time) on most of our circuits, after this all was tranquil again. I noticed that the cables most affected during these storms were invariably those running east and west.—Yours, &c.,

Syra, Greece, 1st Sept., 1892. W. H. COTTRELL.

[A number of reports from cable stations of the storm of July 16 appeared in *The Electrician* of Aug. 5, 1892, p. 358.—ED. *E.*]



Earth potentials observed at the Syra Station on the Syra-Zante Cable (*via* Corinth) during the electric storm of July 16, 1892, at 7:50 p.m. Greenwich time. Direction of Cable, E. and W. Resistance of Circuit, 2,790 ohms. Readings observed every five seconds.

Maximum positive potential	111 volts
,, negative ,, ...	76 ,,
,, positive current	40 milliamperes
,, negative ,, ...	27 ,,
Total difference of potential	187 volts

ELECTRICITY IN THE ROYAL NAVY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the very interesting Paper on this subject by Mr. H. E. Deadman that you publish in your issue for the 16th inst., perhaps I may be allowed to point out that it is not, I think, correct to attribute the credit of the introduction of electricity for the temporary lighting of ships under construction to Portsmouth dockyard. I think I am right in believing that this arrangement was first adopted at the Elswick ship-yard of Messrs. Sir W. G. Armstrong and Co. by Mr. W. H. White, who is now Director of Naval Construction in the Admiralty, but who at the time was director of Messrs. Armstrong's yard. It may also be mentioned that the introduction of lead-coated wires for ship wiring, which, in Mr. Deadman's opinion, constituted an important improvement, was also due to the Elswick firm, having been first employed in the electric lighting of the Japanese cruiser "Naniwa-Kan," which was fitted at Elswick under my superintendence. Mr. Deadman does not mention the name of the firm that has been successful, alone amongst English makers, in satisfying the Admiralty requirements in the manufacture of search-light mirrors. Messrs. C. A. Parsons and Co., of Newcastle-on-Tyne, are the firm in question.

I think that the above remarks may prove a useful supplement to Mr. Deadman's paper, which is specially valuable as showing the important influence that the English Admiralty has had in the development of electric lighting on board ship.—Yours, &c., A. A. C. SWINTON.

66, Victoria-street, London, September 19, 1892.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Postmaster-General invites tenders for the supply of red fir telegraph poles and for creosoting the same. Forms of tender may be obtained of Mr. Charles E. Stuart, Controller of Stores, Telegraph-street, E.C., and tenders will be received up to noon on Friday, October 21st. Further particulars appear in our advertisement columns.

——— Our advertisement columns contain particulars of the requirements of the Lancashire and Yorkshire Railway for stores, &c. Included in the stores required are copper, copper rivets and washers, india rubber, copper boiler tubes, timber, castings, iron and steel sheets, &c. All further particulars, with forms of tender, may be obtained at the Stores Department of the Company, Osborne-street, Manchester, where samples can also be examined before tendering. The Company desire that intending tenderers shall examine these samples. Tenders addressed to the Directors must be in by 10 o'clock a.m., on Monday, the 3rd October, and tenderers are requested to state the particular contracts for which they desire to tender, as separate forms of tender are provided for each contract.

——— It will be seen from our advertisement columns that the Glasgow Corporation Tramways Committee invite parties desirous of submitting estimates to equip certain of their tramway routes for working on the overhead system to communicate with Mr. John Young, City Chambers, Glasgow.

——— The Corporation of Burnley invite tenders for the supply and erection of machinery and plant for their central station, and for underground cables. The plant required consists of steam boilers and engines, fuel economisers, travelling cranes, dynamos, accumulators, switchboards and cables. Specifications, forms of tender and all other particulars may be obtained from Jno. P. Leather, Gas Works, Burnley, and tenders are to be in by October 26th. For particulars see our advertisement columns.

——— The Great Western Railway Company are inviting tenders for stores, including chemicals, lamp glasses, globes, tubes, &c., india-rubber goods, telegraphic apparatus and iron work, copper, iron, and steel wire, metals, rivets, bolts, nails, screws, telegraph poles and yellow pine, &c., &c. Tenders have to be in by October 3rd.

——— The London, Tilbury and Southend Railway Company invite tenders for various stores including iron castings, nails and screws, English and foreign timber, patent metals, forgings, copper, brass, bronze, and gun-metal, india-rubber goods, packing, cotton waste, &c. Tenders have to be in by noon of the 28th inst.

PLANT FOR SALE.—An advertisement elsewhere gives particulars of a small complete electric light plant for sale.

TENDERS RECEIVED.—The Electric Lighting Committee of Whitehaven have recommended the Town Council to accept the following tenders in connection with the electric light scheme:—Messrs. Ramsay Brothers, Whitehaven, for iron and steel work for foundations of engines and dynamos; Galloways (Limited), for two boilers; Messrs. Willans and Robinson, for four sets of Willans engines and Crompton dynamos; and the International Okonite Company (Limited), for conductors.

TENDERS ACCEPTED.—The following tenders have been accepted by the Vestry of St. Pancras in connection with the extension of arc lighting:—

	£	s.	d.
Contract No. 1:—			
Messrs. J. Smith and Co., for supplying 50 small columns (each)	9	10	0
Messrs. Johnson and Phillips, for supplying 5 large columns (each)	13	10	0
Contract No. 3:—			
Messrs. W. T. Henley's Telegraph Works Company (Limited), for supplying insulated cables, &c.	516	1	3
Contract No. 4:—			
Messrs. C. E. Firmstone and Bros., for supplying cast iron pipes, &c.	193	11	8
Contract No. 5:—			
Messrs. Reid Bros., for laying pipes, &c., constructing manholes, erecting lamposts, &c.	1,171	13	4

No tender for lamps has yet been accepted.

FAWCUS AND COWAN'S PORCELAIN CABLE SUSPENDERS.—Messrs. Fawcus and Cowan have appointed Messrs. Bullers (Limited) sole licensees to manufacture and sell their patent porcelain cable suspender.

PRINTS OF OLD TELEGRAPH SHIPS.—If any of our readers are possessed of litho prints of any of the old telegraph ships, especially those which were engaged in laying the early Atlantic cables, they are invited to communicate with "Telegraphs," care of *Electrician* Office.

COX, ROBINSON, AND CO.—The following figure as creditors for amounts of £20 and over under this failure:—

	£	s.	d.
James Bell, Liverpool	30	0	0
Edison & Swan United Electric Light Co.(Ltd.)Londn.	179	7	0
Electric Construction Corporation (Ltd.), London	29	17	5
Walter T. Glover and Co., Salford	43	17	3
Higson, Southport	31	10	0
Kendrew, Southport	34	10	0
J. McIntyre, Burslem	94	0	0
Nixon, Liverpool	33	5	0
Sadler, J., Liverpool	100	0	0
Sanogen Ventilating Co., Liverpool	26	10	1
Selig, Sonnenthal, and Co., London	16	3	6
Thomas, Birkenhead	30	15	0
Thompson, Liverpool	34	0	0
J. Townend, Manchester	145	0	0
Watts, Liverpool	34	0	0
Woodhouse & Rawson United (Ltd.), London	85	4	0

The total liabilities are estimated at £1,627. 19s. 2d., and the assets (after preference claims) estimated to realise £873. 17s. 2d.

J. E. H. GORDON AND CO.—A contract has been entered into between this firm and the Windsor and Eton Electric Company for the erection of an electric light station, &c., at Windsor, to be ready about Christmas.

DISSOLUTION OF PARTNERSHIP.—The partnership hitherto existing between Messrs. Mottershall and Clarke, 41, Corporation-street, Manchester, electrical engineers and agents, has been dissolved.

THE UNPLEASANTNESS AT PONDER'S END.—We are glad to say that the misunderstanding at the Edison and Swan Company's Works has been arranged to the satisfaction of all parties.

REMOVAL NOTICES.—The offices of the New Telephone Company have been removed from 110, Cannon-street, to "The Telephone Exchange," 58 and 59, London-wall, E.C.

——— The head offices of the Westminster Electric Supply Corporation (Limited) have been removed to the central station at Eccleston-place, Belgravia, S.W.

——— The offices of the Electrical Coal-Cutting Contract Corporation (Limited) have been removed to 17, Victoria-street, London, S.W.

——— Messrs. William Bryden and Son announce that they have removed from 112 to 300, St. Vincent-street, Glasgow.

TEMPORARY LIGHTING.—A successful temporary installation was carried out by Messrs. Rawlings Brothers, of Gloucester-road, S.W., last Thursday, on the occasion of a garden party given by Mr. Burdett-Coutts, M.P., at Holly Lodge, Highgate. The incandescent lamps were run off Epstein accumulators.

AWARD.—Messrs. W. Wilson and Co., electrical engineers, have been awarded a silver medal for their exhibit at the Middleton Agricultural Society's annual show.

BELL'S ASBESTOS COMPANY.—This Company have recently issued illustrated price lists and particulars of their asbestos-packed water gauges, boiler and cylinder, gas, main, and angle cocks, blow-off and fire cocks, and of their asbestos-faced valves. Copies of the new price lists can be obtained on application to the Company.

ELECTRO-HARMONIC SOCIETY.—The opening concert of the forthcoming season will be held at the St. James's Hall Restaurant, on Friday next, the 30th inst., at eight o'clock.

ALLEGED FORGERY.—William Bunday was charged on Wednesday last at the Mansion House, London, with forging the names of Messrs. Heale and Douglas, Directors of Messrs. R. C. Cutting, Douglas and Co. (Limited), electrical engineers, of Wardrobe-chambers, London, E.C. It was stated that the prisoner, as secretary to the Company, had forged the names to cheques for £6 and £2. 8s. 9d., and had obtained payment at the City Bank. He was committed for trial.

ABERYSTWITH.—There is to be a temporary lighting of the Marine-terrace, Aberystwith, by electricity, with a view to its being ultimately permanently adopted.

BELFAST.—At a special meeting of the Corporation held on Wednesday last the question of electricity v. gas for lighting the city was under consideration, and a special committee was appointed to present a report on an early day. The London Central Stations are shortly to be visited by local representatives.

BILSTON.—It has been decided to advertise for tenders for the storage plant for use in the market lighting.

BOLTON.—It is proposed to extend the electric light installation at Bolton, and tenders have recently been submitted to the Gas Committee with this object. It is ultimately intended, we understand, to extend the installation throughout the borough.

BRIDGEND.—The Local Board have decided to appoint a sub-committee to inspect the electric lighting of Lynmouth, with the view to the adoption of the electric light for Bridgend.

BUXTON.—On Friday last, at a meeting of the Buxton Local Board, Mr. Willoughby, the secretary of the Buxton Gardens

Digitized by Google

Company, suggested that the electric light should be installed in the gardens. He said that at the Gasworks there was steam and water-power, and he suggested that a central station should be erected there. It is agreed that the necessary information should be obtained and be laid before the Board at the next meeting, it being understood that the Board will itself take the matter in hand.

DOLGELLY.—In reference to the paragraph which appeared in our issue of the 9th September water power will be used in this installation, which is to be completed by the end of the present month. The contract consists of about 60 lamps, and is undertaken at the same price as that paid to the Gas Company at present.

DUNDALK.—We understand arrangements have been made for renewing the Provisional Lighting Order obtained by the Town Commissioners in 1885, the Commissioners having still under consideration the question of introducing the electric light.

FIUME (AUSTRIA) —The Town Council of Fiume invites tenders up to October 1st for the building and working of a tramway in their town. Contractors are at liberty to use electricity as the motive power.

FLEETWOOD.—The Fleetwood Improvement Commissioners at their last meeting decided not to entertain the offer of the Fleetwood Gas Company for the purchase of their works, a desire being expressed that a comprehensive scheme for lighting the town by electricity should be introduced. Estimates have, we understand, been already received by the Commissioners, and in addition four other firms are preparing tenders, the firms who have previously tendered being allowed an opportunity to revise their offers.

GLASGOW.—The Corporation's electric lighting installations at Glasgow is progressing rapidly, and a large number of private firms in the central districts of the city have decided to adopt the electric light, and are having the necessary wiring and fittings put in.——A series of articles is appearing in the *Glasgow Herald* dealing with the question of Cables *v.* Electricity for tramways.

HASTINGS.—The Hastings Town Council have decided that in future the electric light is to be the sole illuminant of the Hastings and St. Leonards parades. They have accepted the offer of the Hastings Electric Light Company to provide 52 arc lamps, 80 yards apart, for three years at £25 per lamp per annum. A saving of £68 per annum is estimated to result as compared with the cost of the present system of lighting by gas and electricity.

HORNSEY.—At the last meeting of the Hornsey Local Board the question of supplying the electric light to the district of Crouch End was referred to the Lighting Committee.

JAMAICA.—The Kingstown (Jamaica) papers to hand contain particulars of a meeting of the City Council at which they discussed the report of a select committee appointed to deal with the question of the lighting of the city with electricity. The Committee have decided to ask the local Electric Light Company for a plan showing the suggested lighting arrangements. The Company offer to supply, for one year, 50 arc lamps at a cost of £30 per lamp per annum, such lamps to have a candle-power of 60,000 as against the 4,200 candles of the present gas lighting, which costs £1,950 as against the £1,500 estimate of the Electric Lighting Company. As at present constituted the gas works, which practically belong to the local authority, are carried on at a loss. The proposal to introduce the electric light finds considerable favour with the local press.

LEICESTER.—Tenders have been received for laying the necessary mains for lighting the town of Leicester, and in all probability the Council will be recommended by the Gas Committee to carry out the terms of the lighting order, which has been in abeyance for some time.

PLYMOUTH.—The Lighting Committee of the Plymouth County Council have had under consideration the desirability of lighting the town with electricity. The matter will be again discussed later.

ROMNEY MARSH.—The new Romney Corporation have under consideration the introduction of the electric light into the borough.

SCARBOROUGH.—The Electric Lighting Sub-Committee, at their meeting on the 16th inst., reported that they had instructed Mr. Bernard Drake to prepare a report as to the terms on which he would advise the Corporation to transfer their powers under the Provisional Order to a Company. The Sub-Committee's report was adopted.

TAUNTON.—The *Somers t Express* of September 17th contains the correspondence which has recently taken place between the Town Clerk and the Laing, Wharton, and Down Construction Syndicate (Limited), in reference to the appointment of an expert to report upon the electric lighting installation in the town. At the meeting of the Council on the 13th instant the Mayor stated that any opposition to the electric light would be received with regret, the only question being whether it would pay the Corporation to take over the electric lighting works; he had looked over the file of a local paper of 16 years ago with reference to the purchase of the water works, and found that in that case it was prophesied that the Corporation would suffer a considerable loss, instead of which a very large profit had resulted. In the result the report of the Committee recommending that the Council should purchase the electric lighting works was adopted, in spite of some unusual opposition.

COMPANIES' MEETINGS & REPORTS.

The Direct Spanish Telegraph Company (Limited).

The thirty-eighth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, E.C., on Tuesday last, under the presidency of Sir James Anderson.

The MANAGER (Mr. Charles Gerhardi) read the notice convening the meeting and the minutes of the last meeting, which were confirmed by the present meeting and signed by the chairman. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I may preface my few remarks by saying that I have scarcely anything to tell you. You may remember that at our last meeting in March I called attention to the reduction of our tariff by ½d. per word, and said that if the traffic did not increase our loss would be £1,700 odd. But I was also in a position to say that the growth of the Spanish traffic which had resulted from the Commercial Treaty with Spain in 1886 had continued, that we had carried 7,900 more telegrams, or 43,000 more words, than in the corresponding period of the previous year, and that in each year from 1886 there had been a continuous growth, so that we did not take a despairing view of the loss of that ½d. per word which the Conference had inflicted upon us. Now this half-year there has been an increase of 10.000 telegrams compared with 7,900 in the corresponding period last year, or 130,000 words as compared with 43,000 last year. I am obliged to say, however, that this is not all the result of normal growth, as the merchants using our lines, with the object of getting their goods into Spain before the treaty expired in June last, employed our cables very freely. Still, one thing with another seems to force merchants into the use of the telegraph, and once they become accustomed to carrying on their business by telegraphy, they do not easily fall back upon the old method of letter writing. I hope this is as I put it, because it is the mainstay of our revenue. There is never much good in abnormal events, which stimulate telegraphy for a time, with the result of shrinkage, depreciated currency, and a good deal of bankruptcy after the undue inflation consequent, say, upon war or the formation of all sorts of companies. Telegraphy, in my opinion, does best when the business pendulum swings both ways with a profitable result. Of course I do not know whether we are now in this safe position, but it is enough to know that since the treaty expired on June 30th, the growth of our traffic is still on the increase. The reduction in the length of the messages by codifying has ceased, and we are now one word per message better than we were a few years ago, when there seemed no end to the ingenuity of code makers. Without attempting to prophesy or forecast the result of the future I think we must let it take care of itself. Three minutes to Bilbao and twenty minutes to Madrid for a telegraph message comes as near dealing with your foreign correspondent in the same room as can be desired. I pass over paragraph 3 of the report, referring to a slight increase in working expenses, as hardly calling for any special remark; and paragraph 4 is a comfortable record of no expenditure upon repairs. Paragraph 5, however, may remind you that I said at our last meeting that your Directors looked forward to replacing the £2,376 which we had taken from our reserve for the repair of our Bilbao cable out of future profits, and that our opinion was we should not pay more than 4 per cent., or even less, if need be, until this was accomplished. You know we had what we called a contingency fund which also had to be expended. Now we are looking forward to the renewal of our Six per Cent. Debentures at a lower rate in 1894, but that will greatly depend upon our re-instating our reserve out of profit, and even providing another contingency fund. I cannot say I see the latter, the contingency fund, but I do not take a gloomy view of our prospects. Much depends upon freedom from breaks and expensive repairs. Still, I make this statement as showing you the policy your Directors desire to pursue—a policy which, if carried out, will maintain your shares as a good investment with as little fluctuation as one sees among the better securities in the list of the London Stock Exchange. That is all I can find to tell you, and I thought really that I should have nothing to say to you. We are making a very fair revenue, and we must be satisfied with it. I have no idea what may happen at the next Conference, which I am happy to say is three years off, and ideas which the Post Office and the European Powers may be entertaining, may be modified after that. At present they are talking—and I hope it is only talk—of a uniform European tariff: but I think from the way things are going on that a good many governments are losing by their telegraphs. The Australian colonies want to put up the tariff, and I hardly expect that there will be any great desire to lower the tariffs. It will not pay to do so. You cannot lower the tariff without making a loss, and 4 per cent. is not too much—it is really not enough—to pay in this class of enterprise. With these remarks I move—

"*That the report and accounts now presented be and are hereby received and adopted.*"

Mr. EDMUND ETLINGER seconded the motion.

The CHAIRMAN: If any gentleman has any remarks to make I will do what I can to reply to them. If not, I will ask your approval of the motion.

The resolution was carried unanimously.

Digitized by Google

The CHAIRMAN: The next resolution is--

"*That the dividend at the rate of 10 per cent. per annum, less income tax, on the preference shares, and a dividend at the rate of 4 per cent. per annum on the ordinary shares, free of income tax, both for the half-year ended June 30, 1892, be and are hereby declared.*"

Mr. ETLINGER seconded the resolution, which was unanimously agreed to.

Mr. COCHRAN said he was sure he was only acting in accordance with the feelings of the shareholders generally when he proposed a vote of thanks to the Chairman for his able conduct in the chair, and to the other Directors also, for their management of the business in the past half-year. The shareholders felt that the position was not quite so bright as they would like to see it; but, taking everything into consideration, he thought they had reason to be satisfied.

The motion was seconded, and unanimously approved.

The CHAIRMAN: On behalf of my colleagues and myself I am extremely obliged to you for the confidence you have expressed in us. It is all very well to wish for good times, but if they will not come what can we do? In face of the fact that we must have our debentures replaced in 1894, I think we must make ourselves as strong as we can. I am sorry that I have not had anything more cheering to tell you. I thank you again, on the part of my colleagues and myself, for your confidence in us.

The meeting then separated.

NEW COMPANIES, STATUTORY RETURNS, &c.

ELECTRO ALKALI (LIMITED).—This Company was registered on the 20th September with a capital of £160,000, in £10 shares. The objects are:—To enter into and carry into effect with or without modification an agreement to be made between the Electric Construction Corporation (Limited) of the one part and this Company of the other part, providing for the acquisition by this Company of the patents and patent rights and licences in the said agreement, to purchase or otherwise acquire any other inventions, patents, patent rights, &c., relating to any chemical, electrolytical, electro-chemical, or other processes or to any apparatus, implements, or machinery for or in connection with electricity and generally to develop, improve, bring into public notice and use the said or other inventions. The subscribers are— Shares.

W. Young, 109, Grofton-road Peckham-road, S.E.	1
F. J. Allen, 14, Trelawn-road, Brixton, S.W.	1
F. Virgo, 93, Earl's Court-road, S.W.	1
W. H. McCarthy, 101, Brook-street, Kennington, S.E.	1
J. Payne, 5, Richmond-terrace, Clapham-road, S.W.	1
J. R. Threadfold, 19, Shenley-road, Camberwell	1
S. T. Bishop, 6A, York-grove, Peckham, S.E.	1

The number of Directors is not to be less than three nor more than seven (including Managing Director), the first to be appointed by the above-named signatories. Qualification for Directorship to be £100, remuneration £100 per annum each, and 10 per cent. on gross profits, and also 10 per cent. on the amount realised by certain sales of patents, the said remuneration to be divided as they themselves determine.

LONDON HEALTH ELECTRICAL INSTITUTE (LIMITED).—A company has been registered under the above title, with a capital of £10,000 in £1 shares, to adopt and carry into effect an agreement between G. J. Spalding and M. C. Spalding and T. J. Henderson, to acquire, develop, and carry on the businesses carried on under the following titles:—"*The Magneto-Electric Battery Company*," and "*The London Health Electrical Institute*," or "*The Health Electrical Institution of London*," to provide for the treatment of diseases by electricity, and to carry on the business of manufacturers of and dealers in electrical appliances.

NEW ELECTRICITY SUPPLY COMPANY OF CROYDON (LIMITED).—This Company has been registered with a capital of £40,000, divided into 7,900 ordinary shares of £5 each, and 100 Founders' Shares of £5 each. The objects are:—To tender for the transfer to the Company, and subsequently to become transferees of all or any of the powers and obligations conferred by or appertaining to the undertakers under the Croydon Corporation Electric Lighting Order, 1891; to obtain by purchase, lease, or otherwise, land and premises suitable for the erection of a central electricity supply station, and all works connected therewith, to be situate in Croydon, in the county of Surrey, and generally to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers and dealers in all or any of the apparatus and appliances necessary for or connected with the generation, distribution, supply, accumulation, and employment of electricity. The signatories are: Shares.

Richard Binnie, 8, Forest-rd., Forest Gate, E.	1
David Pitcairn, 7, New-sq., Lincoln's Inn, W.C.	1
Martin Taylor, 11, Southbridge-rd., Croydon	1
Edward E. Henderson, 12, Lancaster-place, N.W.	1
William F. Taylor, Boswell-ct., Croydon, Electrical Engineer	1
John W. B. Unwin, 58, Southbridge-road, Croydon	1
Charles E. Harrison, 263, Strand, W.C.	1

The number of directors is not to be less than three nor more than seven exclusive of managing director. In connection with the above, a company was registered on June 28, 1889, with a capital of £5,000 in £5 shares, under the name of "The Croydon Electric Supply Company (Limited)." Only seven shares have been taken up in this latter concern.

OZONE SYNDICATE (LIMITED).—This Company was registered on September 15th with a capital of £25,000, in £5 shares, by Mr. Sydney Morse, 4, Fenchurch-avenue, E.C. The objects are to carry on within the United Kingdom the business of ozone producers, sugar refiners, engineers and contractors, manufacturers of sugar refining machinery, and other apparatus; electrical, mechanical, and chemical engineers, and any other business which may be considered to be conveniently carried on by the Company; and to acquire lands, works, property, premises wherever convenient, patents, patent rights, &c. The signatories are:— Shares.

John Raworth, 49, Queen Victoria street, E.C. (Chief Engineer to the Brush Electrical Company)	1
B. Broadhurst, 2, Glenthorn Villas, Surbiton, S.W.	1
W. C. Manns, 19, Upper Kyverdale-road, N.	1
R. A. Dawburn, Wandsworth, S.W.	1
G. B. Mee, 93, Leadenhall-street, E.C.	1
W. W. Gold, 23, Leadenhall-street, E.C.	1
J. Hepper, 34, Burney-street, Greenwich, S.E.	1

Registered office, 39, Victoria-street, S.W.

MISCELLANEOUS.—PATENT AUTOMATIC COUPLER SYNDICATE (LIMITED): Capital £10,000, in £1 shares. To acquire, develop, work, and turn to account Patent No. 2,129 of 1887.——CAMBRIAN ESTATES (LIMITED): Capital £50,000, in £1 shares. Includes the supply of electric light on the estates to be acquired by the Company.——AUTHORISED DISINFECTOR COMPANY (LIMITED): Capital £3,000, in £1 shares. Sanitary, mechanical and electrical engineers, sanitary inspectors, builders, &c.

PIONEER TELEPHONE COMPANY (LIMITED).—A copy of the resolution for the winding up of the above-named Company has been duly filed at Somerset House.

TELEPHONE COMPANY OF AUSTRIA (LIMITED).—The ninth annual return of this Company, made up to August 16th, has been filed. The Company was registered on April 27, 1883, with a capital of £100,000, in £5 shares, to acquire from the Consolidated Telephone Construction and Maintenance Company (Limited) and the Edison-Gower-Bell Telephone Company of Europe (Limited) certain concessions for the establishment and working of telephonic communication in the towns of Prague, Graz, Trieste, Lemberg, Reichenberg, Pilsen, Czernowitz, Bielitz-Biala, and Cracow, granted by the Government of the Austrian Empire, and to carry on in the Austrian Empire the business of a telephone company and an Electric Light, Heat, and Power Supply Company in all or any of their respective branches. In consideration for these concessions, 6,000 shares were allotted as fully paid to Sir Julius Vogel, Colonel George E. Gouraud, and Sir Alexander Armstrong; and in consideration for other interests, 2,000 shares were issued as fully paid to the Consolidated Telephone Construction and Maintenance Company (Limited). By special resolution, passed June 17, 1886, the capital was increased to £200,000 by the creation of 20,000 Preference shares of £5 each. At the time of making up, 11,703 Ordinary and 7,358 Preference shares had been taken up, of which a total of 11,553 Ordinary shares had been issued as fully paid. Upon the remaining 150 Ordinary and the 7,358 the full amount had been called, and all calls (£37,540) had been paid.

CITY NOTES, &c.

BABCOCK AND WILLCOX (LIMITED).—The first ordinary general meeting of this Company was held on Tuesday last. Mr. Andrew Stewart, who presided, stated that those shareholders who held shares during the half-year ended December received an interim dividend of 10 per cent. on ordinary, and six per cent. on preference shares, which absorbed £8,471 of the half-year's profits. The dividend now paid was 15 per cent. on the ordinary and six per cent. on the preference shares which would absorb £13,500. Adding that amount to the interim dividend, the total amount paid in dividends for the year will be £21,971. Other profits had been made, but were put aside, in the form of £19,079 in the reduction of values of various accounts and £9,459 to be carried forward to the credit of next year. With such a favourable balance-sheet, some of the shareholders might think they ought to pay a larger dividend and to carry a smaller sum to next year, and reduce by a smaller amount the various accounts enumerated. These points were carefully cousidered by the board, who had decided to act on the same safe and sound lines which distinguished it as a private company. The plant and machinery had been kept up in excellent condition, and modernised and improved where needed, in order that they might hold that front position which we now occupy in the manufacture of water tube boilers. The Directors' report and accounts were adopted unanimously.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended Sept. 18th were £744, as against £684 for the corresponding period of last year, being an increase of £60. The total receipts for half-year amount to £9,203, against £8,418 in the corresponding period of 1891, being an increase of £785.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment on the 14th October next of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the preference shares of the Company for the quarter ended September 30th; and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income-tax, in respect of profits for the quarter ended June 30th. The register of transfers will be closed from the 7th to 14th October, both days inclusive.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the quarter ended 30th June last of 2s. 6d. per share,

Digitized by Google

free of income tax, payable on 15th Oct. prox. The share register will be closed from the 7th to 14th Oct., both days inclusive.

GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).—This Company have declared an interim dividend of 1s. 9d. per share payable October 18.

PHONOPORE COMPANY (LIMITED).—Mr. Henry Grierson, a Director of the North British Railway Company, Mr. Henry Seebohm, Mr. Forster Webster, and Mr. Arthur Rust have joined the Board of this Company. The Right Hon. Sir Mountstuart E. Grant-Duff has been elected Chairman, and Mr. C. E. P. Spagnoletti, M.I.C.E., Managing Director.

ROCKHAMPTON (QUEENSLAND) GAS AND COKE COMPANY.—Messrs. William Coward and Co., of Queen Victoria-street, E.C., notify that they are prepared to pay the dividend on the shares of the above Company due to English shareholders for the six months ended June 30 last, at the rate of 10 per cent. per annum. This Company is also an electric lighting company, and reference is made to the Directors' report in our issue of September 9.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated receipts of this Company for the fortnight ended Sept. 15, 1892, were £2,146, compared with £1,844 for 1891, showing an increase of £302.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Sept. 16, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,584.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 750.—Vol. XXIX. FRIDAY, SEPTEMBER 30, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

Every year now shows a decided diminution in the number of electric lighting Provisional Orders granted by the Board of Trade and confirmed by Parliament. In 1890 no less than 74 Orders were granted, in 1891 the total was reduced to 58, and this year the total is only 24. This progressive decrease was to be expected, and is not altogether unsatisfactory. When an appreciable proportion of the Orders now in the hands of Local Authorities are being worked, and the remainder have been revoked, it will be time enough to "ask for more."

At the present moment there are nearly 200 Orders in force in the United Kingdom, more than half of which have been obtained by Town Councils, Vestries, Local Boards, &c.; and yet, associating the municipalities who have stations actually at work with those who have signed contracts for plant, it will be found that only about one-sixth of the existing municipal Orders have been made use of. This would seem to point to one of two things: either all the remunerative territory has already been occupied, or the majority of Local Authorities regard their Orders merely as a means of stifling private enterprise. In either case a little breathing time would seem advisable—except, perhaps, from the point of view of the company promoter.

A number of investigations of the efficiency and life of glow lamps have recently been published, but in many cases only one or two makes of lamps have been examined, and the tests being carried out under different conditions, they could not readily be compared together. The most important information to a large number of our readers is the efficiency of ordinary modern Edison-Swan lamps, and the only tests of these that have been published appeared in our columns on July 15 last. We have not given much attention to tests of American lamps as it is unlikely that these will be imported into this country, but the article which we have translated from *L'Electricien* and which will be found in another column, contains an account of an investigation of a number of continental lamps, several of which will doubtless be put upon the English market as soon as the present patents expire.

The tables and the curves in M. Haubtmann's article give, together, a very good idea of the important features of the different glow lamps which he has examined. The first column of the tables shows the number of lamps, commencing in each case with ten, which survived after successive intervals of 250 hours. The lamps were tested at two slightly different voltages—a very good idea. It may be observed, for example, that in the first lamp, made by the Compagnie "La Française," no lamps gave way after 250 hours, either at 102 volts or at 110; one gave way at 102 volts after 500 hours, and two at the higher pressure after the same run. At 750 hours, seven lamps remained in each set, and no further extinction took place at 102 volts at the end of 1,000 hours, while at 110 volts one more lamp had failed, leaving six. A very different state of things is to be found in the second table which refers to a Siemens lamp. This was, perhaps, one of the cheap, short-lived, but not necessarily nasty, kind which are "made in Germany." After 250 hours one lamp out of ten gave out at 102 volts, and four had gone at 110 volts. After 500 hours two more failed at the lower pressure, and only four remained at the higher. After 750 hours three survived in each batch, and of these two remained at 102 volts after 1,000 hours, but the whole ten had succumbed to 110 volts. The diminution of candle-power and the falling off of the current, except in the Siemens lamps where there seems to be a rise, is clearly shown. The curves relate not to the behaviour of the batches but to the characteristics of one sample lamp in each case. Though briefly recorded, this is one of the most instructive investigations on the subject that has been published.

If heat were as difficult to measure as light, our knowledge of many branches of science would be very much impeded, since all energy tends to degrade into heat. In the present issue two instances may be found, the measurement of loss of energy by the rate of rise of a thermometer, and a hot-strip ammeter. The measurement of a rate may often be made with great accuracy, although it involves two terms, because a considerable number of observations can generally be made, and from these not only may the rate be determined, but its constancy or gradual change may be readily found. Calorimetry, on the other hand, requires, as a rule, a number of corrections, and it is only in special cases such as the researches of Messrs. Evershed and Vignoles that the method can be safely adopted. In many examples of thermal measurements, equilibrium is maintained, as in the Cardew voltmeter, the Forbes meter, and the Holden recording ammeter, Langley's bolometer, and Gregory and Boy's methods of measuring radiation.

Digitized by Google

The bi-metallic thermometer was arranged by Breguet to measure electric currents, but the compound strip coiled in a spiral was a very imperfect arrangement. An attempt to construct not only an ammeter but a meter is to be found in the Geyer-Bristol instrument, of which nothing has been heard since its appearance in 1888. Here there was a compound bar, but the coefficient of expansion of the two parts were sensibly equal, for they were of the same metal, German silver, the difference consisting in the shape, the one being a flat strip, the other a wire, the former remaining cooler than the latter by reason of its larger surface. The feature of the Holden arrangement is the great rigidity of the parts, a property in which the Breguet and Geyer-Bristol systems were very deficient.

The selective screening of ether oscillations of different periods will no doubt some day become a matter of importance. Electromagnetic vibrations of 10 or 20 a second may be sifted out from rapid ones of several millions a second by a wet duster, and the limit range of the human eye and ear allow us to confine our attention to sights and sounds without being distracted by the other vibrations which are continually surging around us. By using an alternating current of so high a frequency that ordinary telegraphic instruments will not respond to them, the phonophore system enables telegraphic messages to pass along a line without affecting the ordinary apparatus on the circuit. By adopting exactly the opposite course, Prof. Elihu Thomson proposes to dispense with local batteries on telephone circuits by maintaining an alternating current on the subscriber's lines. As the frequency does not exceed 32 per second, the sound is inaudible. By means of this system the advantages of a closed circuit are provided, but the connections to earth being made through condensers, the lines are not actually put to earth.

It is no doubt a disadvantage for a central station to have connected to its mains a large number of lamps which will, in all probability, never be used, but which, nevertheless, render it desirable to have plenty of spare plant, and it is with a view apparently of mitigating this evil that the Yorkshire House-to-House Company have drawn up a somewhat complicated system of rebates for the benefit of their Leeds *clientèle*.

As will be seen from our Notes column, it is proposed that each customer shall be called upon to declare the maximum number of lights which he intends to have in use at any one time, and he is then to be allowed rebates upon this basis. Thus, a 10 per cent. reduction will be made for not less than 250 hours' use per quarter of the supply demanded, a 20 per cent. reduction for 500 hours, and so on. If the maximum supply is to be fixed by the total number of lamps installed, then we have no hesitation in saying that only a very few of the Company's customers will benefit even by the 10 per cent. rebate. On the other hand, unless each customer is to make an affidavit that he will never use more than a certain number of lights, it would seem that a recording ammeter will have to be placed in every house. In either case the more usual, if less theoretically correct, method of giving rebates, irrespective of all other considerations, to all consumers whose quarterly bills exceed a certain minimum, would appear less likely to lead to disappointment among consumers.

Dublin.—The Electric Light Works have been taken over by the Corporation.

Obituary.—The death is announced at Dresden on the 14th instant of Dr. Proell, inventor of the well-known cut-off gear.

Personal.—Mr. W. H. Cottrell, divisional manager of the Eastern Telegraph Company's (Syra) station, has been appointed Her Britannic Majesty's Consul for the Islands in the Greek Archipelago, with residence at Syra.

Train Signalling.—The Webb and Thompson electric train staff system has recently been introduced on the Cork and Youghal section of the Great Southern and Western Railway, between Queenstown and Youghal, a distance of over 20 miles.

Accrington.—The Legal and Parliamentary Committee of the Corporation have instructed Mr. Shoolbred to prepare plans and estimates for an installation of the electric light at a cost of £10,000. A site has been purchased for the engine-house and generators.

Communication with Lightships.—The Commission holds its next meetings on the 18th, 19th, and 20th prox., when the report of the recent visit paid to the different lightships will be considered, and evidence will be taken from coastguard officers and masters of lightships.

Whitehaven.—Mr. Rienzi Walton, inspector of the Local Government Board, held his inquiry at Whitehaven as to the proposal of the trustees to borrow £14,000 for the purpose of electric lighting on Tuesday last week. There was no opposition. Dr. John Hopkinson gave evidence in support of his plans.

Toynbee Hall.—The newly-formed electrical society at Toynbee Hall will begin its operations this session. Dr. Fison is announced to give two courses of lectures on electricity, one for advanced pupils at Toynbee Hall, and another for beginners at the Limehouse Town Hall. Full particulars can be obtained by writing to the hon. secs. at Toynbee Hall, Whitechapel, E.

The Electric Light in the House of Lords.—According to *The Times*, concurrently with the redecoration of the House of Lords, gas will give place to electric lighting, for which purpose ten electroliers are being made, each containing 36 16-c.p. lights. This addition to the electric lighting installation will increase the total number of lights in the Palace to upwards of 2,000.

Junior Engineering Society.—The Council of this Society announce that the presidency for the ensuing session has been accepted by Dr. John Hopkinson. The new session will be opened by the delivery of Dr. Hopkinson's presidential address on Friday, November 4th, at the Westminster Palace Hotel. On Friday, October 7th, at 7:30, there will be a general meeting for election of officers and other business at the Westminster Palace Hotel.

The Berlin Electricity Supply Company and its Consumers.—It is reported that there has recently been a meeting of electricity consumers in Berlin. They complained of unsatisfactory meters and the excessive consumption of electricity by the glow lamps. The Supply Company maintains that it is already doing more for its consumers in the matter of fittings, meters, tests, &c., than it is bound to do, but states that it is prepared to lower the tariff at the beginning of next year.

Morley Memorial College.—The fourth session at the Morley Memorial College, Waterloo-road, re-opens on October 3rd, when Sir John Lubbock will distribute the prizes. Besides science and other classes, the College comprises a gymnasium, clubs and social meetings, and last year those who had distinguished themselves in the Science and Art, or the University Extension Examinations, were sent by means of scholarships to Oxford or Cambridge during the University Extension summer meeting.

Photographic Society of Great Britain.—We had great pleasure in accepting an invitation to visit the exhibition of the Photographic Society of Great Britain last week, and thoroughly enjoyed the beautiful products of this fascinating art, relieved to be free for a little from electrical matters. But having arrived at No. 407, we found no charming bit of landscape in evening light, or Alpine study, but a portrait of a Raworth Patent Pump and a Mordey 20-Pole Alternator! We fled down the neighbouring stairs, but not without a glance at an extraordinary photograph taken with the newly-invented tele-photographic lens.

Spanish Telegraphs.—We extract the following from the *Revista de Télegrafos* of Madrid, September 16, 1892:—"*The Electrician* of London of August 26th gives an account to its readers of the reforms which are being introduced in the Spanish Telegraph service, and of the concessions granted to the *employés* of the same, finishing by saying, 'The Telegraph Corps have thus gained all the points they sought for, *hasta cierto punto, estimada colega, hasta cierto punto* (to a certain point, estimable colleague, to a certain point).'" We can only express the hope that such other grievances as exist may be removed, but we suppose the *personnel* of no service in the world could be got to admit that they had gained all the points they sought for.

The Production of India Rubber in Nicaragua.—The United States Consul at Managua has lately prepared a report on the state of the india-rubber trade in Nicaragua. After describing the various native modes of working the trees, which are all uniformly destructive, he states that the natural supply of india-rubber is yearly decreasing in Nicaragua. The Government attempts no supervision of the forest; anyone may cut the trees, and great destruction is caused by the young trees being tapped as well as the full-grown ones, but it is an incontrovertible fact that, so far, at least, as Nicaragua is concerned, the rubber tree is susceptible of cultivation, and in the district of Managua there are large tracts of land suitable for growing rubber trees. It is the opinion of those persons in Nicaragua, who are interested in rubber production, that the cultivation and improvement of rubber plantations would be very profitable.

The Popp Company.—The following figures, taken from the recently published report of the Compagnie Parisienne de l'Air Comprimé, may be of interest:—The compressed air produced during 1891 was 166,400,000 cubic metres, as against 180,000,000 in 1890. Notwithstanding this, however, the 1891 total receipts exceeded those of the previous year, the total being £78,320. At the end of 1891 the Company had 3,520 customers, who employed 750 motors having a total horse-power of 2,838; the average motor being, therefore, of about 3¾ H.P. The compressed air mains have a total length of 72 miles, and the electric mains 116½ miles. During 1891, 863,750 kilowatt-hours were generated. The Company possesses 785 tons of accumulators distributed among 21 stations. The loss made up to date is about £16,000. Recently M. Victor Popp has resigned his seat as a Director, and has been appointed consulting engineer to the Company.

Penywern House College.—The complete courses of instruction in the engineering department of this college, of which Mr. G. W. de Tunzelmann is principal, are arranged to qualify students for entrance into the Central Institution, Cooper's Hill, and Engineering Works. Of the 22 students who went up for the Central Institution from Penywern House this year 17 passed, and all who have presented themselves for Cooper's Hill since 1889 have passed. The Physical Laboratory contains an extensive collection of standard electrical and magnetic measuring instruments, a fine collection of optical apparatus, including instruments sent by Prof. Rowland, to the Loan Exhibition of Scientific Apparatus held at South Kensington in 1876, and an ample supply of less delicate apparatus suitable for ordinary students. The Chemical Laboratory is fitted up according to the plan drawn up by Prof. H. E. Armstrong, who designed the Chemical Laboratories at the Finsbury Technical College and at the Central Institution.

Effects of Railway Currents on Fire Alarm Circuits.—In reading your Editorial in your issue of July 30th, says Mr. Chas. C. Drake, in the *Electrical World* of August 6th., in reference to electricity, the supposed mischief maker again, I would like to state that since the electric street car road was started, we have had considerable trouble with our police telegraph circuits, which are grounded. When this road was first started, in less than four days a new 10-cell Callaud battery failed on one circuit. After trying to locate the trouble by reversing the ground, I overcame it. In about three weeks the street car company reversed the polarity to ground, unbeknown to me, and in about three-and-a-half or four days my battery failed again. After reversing the grounds and building up the battery again, all went well. But I find that my batteries do not work as well, and will not last more than half as long. I have had to double them; where I only used 48 before, I now use 96, and they are not as satisfactory as before. I reported these facts to our Board of Commons, and recommended that they make our circuit metallic.

The Electromotive Force of Gas Batteries.—In a Paper on "The Electromotive Force of Gas Batteries," Herr G. Markovsky (*Ann. Phys. Chem.*) has given measurements of the electromotive force developed in elements consisting of platinum wholly immersed in dilute, carefully boiled-out sulphuric acid, and of platinum partially immersed in this liquid, and partially exposed to an atmosphere of pure hydrogen and oxygen. His results are given as follows in the *Journal* of the Chemical Society:—The electromotive force of a platinum plate in hydrogen against a platinum plate in gas-free sulphuric acid is 0·646 volt. When oxygen is substituted for hydrogen, the current is in the opposite direction, and the electromotive force is 0·372 volt. Electrolytic hydrogen, and hydrogen prepared from zinc and sulphuric acid, give the same value for the electromotive force. The same thing holds for electrolytic and chemically prepared oxygen. The electromotive force of an oxygen cell is diminished by the addition of platinum sulphate to the solution, whilst that of a hydrogen cell increases, the sum of the two remaining constant. The electromotive force is independent of the density and temperature—up to 70deg.—of the gas. Carbon electrodes behave quite differently rom platinum electrodes.

Leeds.—About December the Yorkshire House-to-House Electricity Company will be prepared to supply current. An arrangement has been come to with the Highways Committee whereby a Corporation staff are at work opening up the streets along which the mains are to be laid. The standard price of eightpence per unit will be subject to discounts based upon the number of hours per quarter during which the current is used, each consumer being called upon to declare the maximum number of lights required to be in use at any one time. The scale of discounts is as follows:—

For not less than	250	hours' use	(per quarter)	of the	supply	demanded,	10	per cent.
„	„	375	„	„	„	„	15	„
„	„	500	„	„	„	„	20	„
„	„	600	„	„	„	„	22½	„
„	„	700	„	„	„	„	25	„

In addition to the discounts accruing under the above table, a discount of 5 per cent. will be allowed on the net amount of accounts paid within one month from the date of rendering, and 2½ per cent. on accounts paid within two months. The effect of the discounts above mentioned is to reduce the price of eightpence per unit to about the following net charges:—

For	250	hours' use	(per quarter),	6⅝d.	per unit.
„	375	„	„	6¼d.	„
„	500	„	„	6d.	„
„	600	„	„	5⅞d.	„
„	700	„	„	5½d.	„

Finsbury Technical College Evening Classes.—We are requested to announce that all available places in the electrical laboratories of the Finsbury Technical College are already filled for Monday and Wednesday evenings; applicants for attendance at the lectures only can be admitted, but there are still some vacancies in the overflow class in the laboratories on Tuesday nights. The evening lectures will be resumed on October 3rd. In the advanced course on Mondays, Prof. Thompson will lecture on Dynamos and Motors; the intro-

Digitized by Google

ductory lecture on October 3rd being on Magnetic Fields. The Wednesday night lectures will be on Magnetism, and on Instruments till Christmas. For special lectures at Finsbury there will be first a short course on Accumulators, by Mr. G. H. Robertson, F.C.S., on Thursday evenings, commencing October 6th, and one on Gas and Oil Engines, by Prof. Perry, F.R.S., on Thursdays, commencing October 20th. This will be accompanied by a drawing-class for machine design in Gas and Oil Engines, conducted by Mr. Johnston on Monday evenings. Mr. Clinton gives four lectures on Vector Calculations on Tuesdays, beginning October 22nd. Prof. Perry will also hold throughout the winter a Friday evening course of lessons on the Applications of Higher Mathematics to Engineering Problems. After Christmas Prof. Silvanus Thompson, F.R.S., will lecture on Central Stations, and there will be a course of laboratory lessons in Electrotyping and Electroplating, by Mr. Rousseau.

Electric Lighting Contracts.—If we may judge by some remarks of M. J. P. Anney, in the last number of *L'Industrie Electrique*, the good name of the electrical industry suffers even more in France than in this country from a propensity for undertaking contracts of which the financial success, doubtful at the best, is rendered hopeless by technical blunders of the first order. In support of his statements, M. Anney cites the case of a town in the south of France where the extraordinary fascination which water power has for some people, led to a company coming to grief before it commenced operations. A waterfall capable of furnishing some 200 H.P., but difficult of access, existed about 4½ miles outside the town in question, in which an ultimate load of 20,000 lamps might reasonably be anticipated. Although the waterfall furnished but a small portion of the total power likely to be ultimately required, it was decided to make the generating station there, thus burdening the undertaking from the beginning with a heavy C^2R loss, a long line of conductors, and a high charge for coal cartage. To further complicate matters two systems of distribution were employed; the centre of the town being lit on the continuous current battery sub-station system, and the rest of the town being supplied with alternate currents. The battery charging current, it should be added, had an electromotive force of only 400 volts. To put a finishing touch to the affair, the work was divided up amongst a multitude of contractors, and, in consequence, mishaps abounded. At the present moment the houses wired for the electric light are still awaiting a supply of current.

The Over-regulation of Electric Lighting.—The following remarks prefaced an article on "Some English Measuring Instruments," which was recently contributed to the New York *Electrical Review* by their London correspondent:—The modern Englishman is never happy unless he is under Government inspection. An inspector is always at hand to prevent the simple-minded John from being cheated. Indeed, so well is his safety and well-being looked after that he has only within the last two or three years been allowed to light his house from electric supply mains. When permission was at last reluctantly given, John would have felt somewhat off the track without Governmental aid and advice if he had not had at his elbow the ubiquitous and almighty fire office inspector. This gentleman, at least, knew his own mind (not a very extensive knowledge, perhaps), and, since the prevention of fire was his end and aim, he insisted on three things—you *must* put your wires in casing, inflammable wood casing, if you like, but still casing; you *must* mount your fittings on incombustible materials, no matter if they are hygroscopic or not, and, finally, the insulation *must* amount to so many megohms. The fire office man was not quite clear whether a megohm was a current or a self-induction, but he knew it was good to have plenty of it; the fact that the supply companies insisted on megohms gave him confidence. And so wiring contractors and fire inspectors and other interested parties wandered around hunting for megohms with $200 Wheatstone bridges and galvanometers and a leaky Leclanché cell or two. No two men ever agreed about the number of them when caught, and it generally took longer to test the wiring in a house than it did to put it in.

Forthcoming Electrical Literature.—Amongst a number of scientific books announced as being in the course of preparation, *The Electrician* Printing and Publishing Company (Limited) have in hand the following: "Electromagnetic Theory," by Oliver Heaviside; "A Pocket-Book of Electrical Engineering Formulæ," by W. Geipel and H. Kilgour; "Submarine Cable Laying and Repairing," by H. D. Wilkinson; "Drum Armature Winding, and Commutators," by F. M. Weymouth; and "Electricity as a Motive Power," by Albion T. Snell. Messrs. Macmillan are about to publish "Researches on the Propagation of Electrical Force," by Prof. H. Hertz, translated by Prof. D. E. Jones; "Electrical Papers," by Oliver Heaviside; "Pioneers of Science," by Dr. Oliver Lodge; "The Theory and Practice of Absolute Measurement in Electricity and Magnetism," by Prof. A. Gray, Vol. II. Messrs. Whittaker and Co. have just issued—"Treatise on Lightning Conductors and Lightning Guards," by Dr. Oliver Lodge, and are about to issue "Electrical Experiments," by G. E. Bonney; "A Comprehensive Work on the Dynamo," by C. C. Hawkins and F. Wallis; "Electric Light and Power Distribution," by W. Perren Maycock; "Practical Electric Light Fitting," by F. C. Allsop. "How to Manage a Dynamo," and "Electricity and Magnetism," by S. R. Bottone. Mr. Murray announces "The Collected Works of Werner von Siemens," translated by E. F. Bamber, Vol. II.; "An Introduction to Physical Science," by John Cox. The Clarendon Press have in hand "Mathematical Papers of the late Henry J. S. Smith, Savilian Professor of Geometry in the University of Oxford," and a supplementary volume to Prof. Clerk Maxwell's "Treatise on Electricity and Magnetism," by Prof. J. J. Thomson. Messrs. Baillière, Tindal, and Cox are preparing "A Manual of Practical Medical Electricity," by Dr. Dawson Turner. Messrs. Charles Griffin and Co. announce "Griffin's Electrical Price Book," edited by H. J. Dowsing; Messrs. Longmans and Co., "Lehrbuch der Elektricität," in 2 vols., translated by G. W. de Tunzelmann, B.Sc.; and Messrs. Crosby Lockwood and Sons, "Electric Ship Lighting," by J. W. Urquhart. Messrs. J. and A. Churchill inform us that they hope to issue next year a work on "Lighting," edited by C. A. Groves, F.R.S., and W. Thorp, B.Sc., to which Prof. Garnett is contributing a section on Electric Lighting.

An Apparent Relation of Electromotive Force to Gravity.—In a research on "A General Relation of Electromotive Force to Equivalent Volume and Molecular Velocity of Substances," I have demonstrated, says Dr. Gore, in the September number of the *Philosophical Magazine*, by means of a large number and variety of experimental measurements, that the *dilution* of the liquid of a voltaic cell by means of water or alcohol, the *solution* of either the positive metal or the negative one by means of mercury, the *dilution* of either of these amalgams by means of mercury, or the *dilution* of one solid metal by means of another in an alloy, is universally attended by an increase of mean electromotive force of the diluted and diluting substances beyond the calculated amount, and therefore of the *actual* electromotive force of the diluted one (that of the diluent being very little affected), provided that no chemical union of the diluted and diluting substances occurs. If, however, chemical union does occur, this gain of electromotive force is diminished, or converted into a loss which is larger in proportion as the union is more intimate. In these experiments, by the act of solution or dilution, the molecules of the active or diluted substance are separated farther apart by those of the neutral or diluting one, and acquire greater freedom of motion, whilst those of the diluent approach only slightly nearer together, and do not perceptibly affect the result. It is generally admitted that the particles of all bodies are in an incessant state of motion, that this motion is the *vis viva* or energy contained in the substance, and that the laws of motion apply equally to the smallest as to the largest bodies. If now we regard each molecule of the active substance as vibrating like a pendulum, its movements must obey the law of falling bodies, and the larger the degree of freedom of motion the greater the arc of vibration, the larger the fall, and the greater the velocity of motion. And as in the above-mentioned experiments the volta electromotive force of substances generally has been proved to vary directly as the degree of molecular freedom, it must also, according to this view, be directly related to, and dependent upon, the velocity of molecular motion and the law of gravity in the above manner.

ELECTROMAGNETIC THEORY.—XXXVII.

BY OLIVER HEAVISIDE.

(*Continued from page 531.*)

§ 165. From the preceding, relating to the magnetic effects produced by moving the medium bodily past stationary electrification; or equivalently, by moving the electrification the other way through the medium; or, more generally, by relative motion of the sources of displacement and the medium supporting it, we may readily deduce the corresponding results when the sources are of the flux induction, instead of displacement. Thus, in (42), (43), do away with the convective electric current $\rho\mathbf{u}$, and substitute convective magnetic current $\sigma\mathbf{u}$, where σ is volume-density of magnetification (suppositional). Our circuital equations are then

$$\text{curl}\,(\mathbf{H}-\mathbf{h})=cp\mathbf{E}, \quad . \quad . \quad . \quad . \quad . \quad (55)$$

$$\text{curl}\,(\mathbf{e}-\mathbf{E})=\mu p\mathbf{H}+\sigma\mathbf{u}, \quad . \quad . \quad . \quad (56)$$

with the auxiliary equations of motional electric and magnetic force

$$\mathbf{e}=\mathrm{V}\mathbf{w}\mathbf{B}, \qquad \mathbf{h}=\mathrm{V}\mathbf{D}\mathbf{w}, \quad . \quad . \quad . \quad . \quad (57)$$

as before, where $\mathbf{w}$ is the velocity of the medium, and with the further auxiliary conditions that the divergence of the displacement is zero, whilst that of the induction is σ. Now we really do not need to employ the formal mathematics. Knowing the results relating to the motion of electrification, we may infer the corresponding ones concerning the motion of magnetification, by making use of the analogies between the electric and magnetic sides of electromagnetism, translating results in the appropriate manner. But as our object is to 'illustrate' the working of vectors as well as electromagnetic principles, it will not be desirable to leave out the mathematics entirely, especially as the safe carrying out of the analogies requires that they should be thoroughly understood first, which requires some practice.

First, if we convert the problem to one of stationary waves, by keeping the sources at rest, and letting only the medium move bodily past them, we have, when the stationary state of induction and displacement is reached, disappearance of the right members of (55) and (56). Then (56) gives, when united with the first of (57),

$$\text{curl}\,\mathbf{E}=\text{curl}\,\mathbf{e}=\text{curl}\,\mathrm{V}\mathbf{w}\mathbf{B}. \quad . \quad . \quad . \quad (58)$$

In the result for a moving point-charge, curl $\mathbf{E}$ is perpendicular to $\mathbf{w}$, so now we may write

$$\mathbf{E}=\mathrm{V}\mathbf{w}\mathbf{B}=\mathrm{V}\mathbf{B}\mathbf{u}, \quad . \quad . \quad . \quad . \quad . \quad (59)$$

where $\mathbf{w}=-\mathbf{u}$, because, similarly, curl $\mathbf{H}$ will be perpendicular to $\mathbf{w}$, and so make $\mathrm{V}\mathbf{B}\mathbf{u}$ circuital. Here $\mathbf{u}$ is the equivalent velocity of the sources, when the medium is stationary. Thus $\mathbf{E}$, and therefore $\mathbf{D}$, are fully known in terms of $\mathbf{B}$. Comparing with (46), we see that the electric force set up when a magnetic charge moves is related to the induction from the charge in the same way as the magnetic force set up when an electric charge moves is related to the displacement from it, with, however, a change of sign, or reversal of direction.

Using the second of (57) in the other circuital equation (55) produces

$$\text{curl}\,(\mathbf{H}-\mathrm{V}\mathbf{u}\mathbf{D})=0=\text{curl}\,\mathbf{f}, \text{ say}, \quad . \quad . \quad (60)$$

where, by (59),

$$\mathbf{f}=\mathbf{H}-c\mathrm{V}\mathbf{u}\mathrm{V}\mathbf{B}\mathbf{u}=\mathbf{H}+\mu c\mathrm{V}\mathbf{u}\mathrm{V}\mathbf{u}\mathbf{H}, \quad . \quad (61)$$

or, if $\mathbf{u}$ is parallel to $\mathbf{k}$,

$$\mathbf{f}=\mathbf{H}+\frac{u^2}{v^2}\mathrm{V}\mathbf{k}\mathrm{V}\mathbf{k}\mathbf{H}=\mathbf{H}+\frac{u^2}{v^2}(\mathbf{k}\mathrm{H}_3-\mathbf{H})$$

$$=(1-u^2/v^2)\mathbf{i}\mathrm{H}_1+(1-u^2/v^2)\mathbf{j}\mathrm{H}_2+\mathbf{k}\mathrm{H}_3; \quad . \quad . \quad (62)$$

from which we see that the vector $\mathbf{F}$ derived from $\mathbf{f}$ by $\mathbf{f}=(1-u^2/v^2)\mathbf{F}$ has no curl, or is derived from a scalar potential Ω thus, $\mathbf{F}=-\mathrm{v}\Omega$, and that the induction is given by

$$\mathrm{B}_1=-\mu\frac{d\Omega}{dx}, \quad \mathrm{B}_2=-\mu\frac{d\Omega}{dy}, \quad \mathrm{B}_3=-\mu(1-u^2/v^2)\frac{d\Omega}{dz}. \quad (63)$$

That is, the induction distributes itself in the same way as if the medium were at rest, but had its inductivity reduced from μ to $\mu(1-u^2/v^2)$ in the line of motion. In fact, the theory of the effects produced by relative motion of magnetic sources and the medium is essentially the same as that of moving electric sources; translating displacement in the latter case to induction in the former, permittivity to inductivity, electric potential (real or fictitious, as the case may be) to magnetic potential, and the magnetic induction which accompanies moving electrification to electric displacement set up by moving magnetification, remembering, however, the change of sign.

We know, therefore, the result of the steady rectilinear motion of any distribution of magnetic sources. If the same motion is common to all the elementary sources, we reduce the problem to that of magnetic eolotropy without relative motion of the medium and sources, and there is a definite system of surfaces of equilibrium ($\Omega=$ constant) where we may, if we please, terminate the electric and magnetic fields, thereby substituting new arrangements of magnetic sources for the old. In this case it is most convenient to keep the sources at rest, and move the medium alone.

But should the relative motion of source and medium not be the same for every source, then, since we cannot move the medium bodily more than one way at a time, we may imagine it to be stationary, and obtain the effect due to the motion of the magnetification by superimposing the separate effects of the elementary sources, which are known by the above.

§ 166. There is, however, no such thing as magnetification, the magnetic analogue of electrification. The induction is always circuital. If it were not circuital, we should have unipolar magnets. We must, therefore, somewhat modify the conditions assumed to prevail in the above, in order to come closer to reality. Consider, therefore, instead of magnetification, a distribution of intrinsic magnetisation. This quantity is $\mathbf{I}=\mu\mathbf{h}_0$, where $\mathbf{h}_0$ is the equivalent intrinsic magnetic force. Abolish σ in (56), and introduce $\mathbf{h}_0$ in (55). The circuital equations are now

$$\text{curl}\,(\mathbf{H}-\mathrm{V}\mathbf{D}\mathbf{w}-\mathbf{h}_0)=cp\mathbf{E}, \quad . \quad . \quad (64)$$

$$\text{curl}\,(\mathrm{V}\mathbf{w}\mathbf{B}-\mathbf{E})=\mu p\mathbf{H}, \quad . \quad . \quad . \quad . \quad (65)$$

where we have introduced the motional forces (57). In the steady state, the right members vanish as before. Now assume that

$$\mathbf{E}=\mathrm{V}\mathbf{w}\mathbf{B}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (66)$$

so that the theory is unchanged so far, the displacement depending on the induction and velocity of the medium in the same way as when the source was magnetification. We shall see the limitation of application later. Next put (66) in (64) and we find, if the fraction $1-u^2/v^2$ be denoted by s,

$$\text{curl}\,\mathbf{f}=\text{curl}\,\mathbf{h}_0, \quad . \quad . \quad . \quad . \quad . \quad (67)$$

$$\text{curl}\,\mathbf{F}=\text{curl}\,\mathbf{h}_0/s, \quad . \quad . \quad . \quad . \quad (68)$$

where $\mathbf{f}$ and $\mathbf{F}$ are the same vectors (in terms of $\mathbf{H}$) as in the last case, such that $s\mathbf{F}=\mathbf{f}$. We see that the vector $\mathbf{F}$ has now definite curl, and that the induction is derived from $\mathbf{F}$ by

$$\mathrm{B}_1=\mu\mathrm{F}_1, \qquad \mathrm{B}_2=\mu\mathrm{F}_2, \qquad \mathrm{B}_3=\mu s\mathrm{F}_3; \quad . \quad (69)$$

that is to say $\mathbf{B}=\lambda\mathbf{F}$, where λ is the inductivity operator whose scalar principals are μ, μ, and μs. We therefore have to find the steady state from these complete connections,

$$\text{div}\,\mathbf{B}=0, \qquad \mathbf{B}=\lambda\mathbf{F}, \qquad \text{curl}\,\mathbf{F}=\text{curl}\,\mathbf{h}_0/s. \quad (70)$$

That is, the induction is the same as in a stationary eolotropic medium (according to λ), provided the intensity of the intrinsic magnetic force be increased from $\mathbf{h}_0$ to $\mathbf{h}_0/s$. This is an important point.

We know that there are certain respects in which the theory of induction due to intrinsic magnetic force is identical with that due to magnetification. For instance, the steady induction outside a magnet due to $\mathbf{h}_0$ is the same as that due to a distribution of σ, measured by the convergence of the intrinsic magnetisation. From this we might hastily conclude that the disturbance from the steady distribution produced by moving the medium would be the same for $\mathbf{h}_0$ as for the equivalent σ, provided we keep outside the region of magnetisation. But the above investigation only partly confirms this conclusion. It

Digitized by Google

shows a likeness and a difference. The likeness is in the eolotropic peculiarity brought in by the motion. In both cases we may do away with the motion provided we simultaneously reduce the inductivity parallel to the (abolished) motion from μ to $s\mu$, so as to cause the induction to retreat from this direction and concentrate itself transversely. The difference is in the reckoning of the strength of sources. In the case of magnetification (as of electrification) we do not alter the strength of the source. But in the case of magnetisation we do, or, at any rate, produce an equivalent result. For, along with the reduction of inductivity in the direction of motion, we require to increase the intensity of the intrinsic magnetic force from $\mathbf{h}_0$ to $\mathbf{h}_0/s$. Remember that s is a proper fraction, going from unity to zero as the speed of motion increases from 0 to v, the speed of propagation of disturbances.

To exemplify this, put

$$\mathbf{F} = \mathbf{h}_0/s - \nabla\Omega, \quad . \quad . \quad . \quad . \quad . \quad (71)$$

as we see we may do, by the third of (70). Using this in the second and first of (70) we obtain

$$\text{div}\,\lambda\nabla\Omega = \text{div}\,\lambda\mathbf{h}_0/s, \quad . \quad . \quad . \quad . \quad (72)$$

the equation of the potential Ω. Or, in terms of Cartesians,

$$\mu(\nabla_1^2 + \nabla_2^2 + s\nabla_3^2)\Omega = \mu s^{-1}(\nabla_1 h_{01} + \nabla_2 h_{02} + s\nabla_3 h_{03}) \quad . \quad (73).$$

The equivalent magnetification is the convergence of $\lambda\mathbf{h}_0/s$, not of $\mu\mathbf{h}_0$ the real intensity of magnetisation, nor yet of $\mu\mathbf{h}_0/s$, the same increased in a constant ratio.

There is, therefore, a remarkable difference between the two cases of motion of the medium parallel to and transverse to the lines of real magnetisation. Thus, first let $\mathbf{h}_0$ be parallel to $\mathbf{w}$ or $\mathbf{k}$. Then the s^{-1} outside the brackets in (73) cancels the s inside, so that the right member becomes simply $\mu\nabla_3 h_{03}$, where h_{03} is now the tensor of $\mathbf{h}_0$. That is, the effective magnetification is the convergence of the real magnetisation, just as when the medium is at rest. But if $\mathbf{h}_0$ is perpendicular to $\mathbf{k}$, say parallel to $\mathbf{i}$, the right member of (73) becomes $\mu s^{-1}\nabla_1 h_{01}$, or the effective magnetification is s^{-1} times the convergence of the magnetisation, and is therefore increased.

Suppose, for example, our magnet is a straight filamentary magnet. It has two poles, of strength m and $-m$ say, so that induction to the amount m diverges from one and converges to the other pole, whilst continuity is made between them in the filament itself. Now let the medium move past the filament, the direction of motion being parallel to it. Then the strength of the poles is unchanged, but the induction outside is diverted laterally by the effective reduced inductivity parallel to the filament. This case, then, resembles that of a pair of oppositely signed point-charges, if we keep outside the filament. In the limit, therefore, when the speed is raised to v, we have a pair of parallel plane induction-sheets whose cores are joined by the straight filament of induction, to make continuity.

For (66) to be valid, $\mathbf{B}$ should be such as to make $\mathbf{E}$ circuital. This requires that $\mathbf{w}$ and curl $\mathbf{B}$ should be perpendicular to one another. They are perpendicular in the example just mentioned, on account of the symmetry of $\mathbf{B}$ with respect to the axis or line of motion. But if the same filament be held transversely across the line of motion the property stated is no longer true, so that (66) is not true, and this will, to an unknown extent, upset the later equations. We can, however, still employ them provisionally to obtain a first approximation to the results. On this understanding, then, the strength of the poles (effective) is made m/s and $-m/s$, with unimpaired effective inductivity parallel to the filament, whilst that perpendicular to the filament is reduced, as before. So there is now an increased total induction as well as concentration about the plane through the filament perpendicular to the motion.

We may, however, arrange matters in such a way that the equation (66) shall be still valid when the line of motion is perpendicular to the magnetisation, and so obtain an exact solution showing the increased induction, that is, exact in the absence of working errors. Let the region of magnetisation be confined between two infinite parallel planes, and the magnetisation $\mathbf{I} = \mu\mathbf{h}_0$ be uniformly distributed, parallel to the boundaries. We thus do away with the poles. Now when the medium is at rest the induction is $\mathbf{B} = \mathbf{I}$ within the plate (which may be of any thickness), and zero outside, whilst there is no displacement. The intrinsic magnetic force $\mathbf{h}_0$ produces the greatest effect that it can produce unaided. But if the medium be made to move steadily straight across the magnetised region, then, after certain transient effects have passed away (which may be readily calculated, because they form simply plane electromagnetic waves), although there will still be no induction (or displacement) outside the plate, that within it will be increased (without change of direction) from $\mathbf{I}$ to $\mathbf{I}/s$. That is, the motional magnetic force comes in to assist the intrinsic magnetic force. Here we have the explanation of the previous result relating to the increased effective strength of poles.

Along with this increased induction, there will be electric force, according to (66). It is entirely within the magnetised region. As the speed increases up to v, the induction and the accompanying displacement in the plate go up to infinity.

The theory of an electrised plate is similar. The displacement due to intrinsic electrisation $\mathbf{J} = c\mathbf{e}_0$, where $\mathbf{e}_0$ is the equivalent electric force, the electrisation being uniform and parallel to the sides of the plate, will be increased from $\mathbf{D} = \mathbf{J}$ to $\mathbf{D} = \mathbf{J}/s$ by setting the medium moving straight through it, it being now the motional electric force that assists the intrinsic. The accompanying magnetic force is accordingly given by

$$\mathbf{H} = \mathbf{h} = V\mathbf{D}\mathbf{w}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (74)$$

Outside the plate there is no disturbance in the steady state.

It will of course be understood that if, instead of suppositional impressed or intrinsic forces in a uniform medium, we employ actual material plates, magnetised or electrised as the case may be, they must, in the first place, be non-conductors, and next, they must not interfere with the supposed uniform motion of the medium. In short, the reservation is similar to that mentioned in connection with moving charged conductors. Of course, in our present case, the plates may be moved, whilst the medium is supposed to be at rest.

It will be readily seen that the full investigation of the effects of moving practicable electromagnetic arrangements of conductors presents considerable difficulties. We can, however, get some information relating to the motion of a linear circuit.

(To be continued.)

ON THE PRODUCTION OF THE SPARK OF A HERTZ OSCILLATOR IN A DIELECTRIC LIQUID INSTEAD OF AIR.*

BY MM. SARASIN AND DE LA RIVE.

We have recently made experiments by placing the two little balls of three or four centimetres diameter, between which the discharge of the Ruhmkorff when used as a Hertz oscillator takes place in an insulating liquid, and we have found that by so doing more powerful effects are obtained at the resonator.

The first liquid employed was olive oil. A cylindrical bottle 20 centimetres in diameter was pierced laterally by two holes into which the horizontal rods of the oscillator were inserted through carefully fitted corks; the two little spheres at the end of the rods being thus immersed in the liquid where the spark took place. When the spark gap was progressively increased the tension of the two terminals soon reached its limit, either because it approximated the maximum tension of the inductor, or because the spark went round by the glass bottle instead of traversing the layer of oil. In our experiments we obtained a spark of a little more than one centimetre. The spark occurred regularly, and was accompanied by its characteristic sound, similar to that of a blow, but it was more intense than in air.

The effect of this device on the resonator was most marked. Close to the oscillator the spark became a positive blaze; and at 10 metres distance in the case of resonators of large diameter, 0·75 to 1 metre, it was still very bright and visible from afar. The electromotive force interferences caused by reflection from a plane metallic surface gave the same results

* From the *Comptes Rendus*, Vol. CXV., No. 12, p. 439.

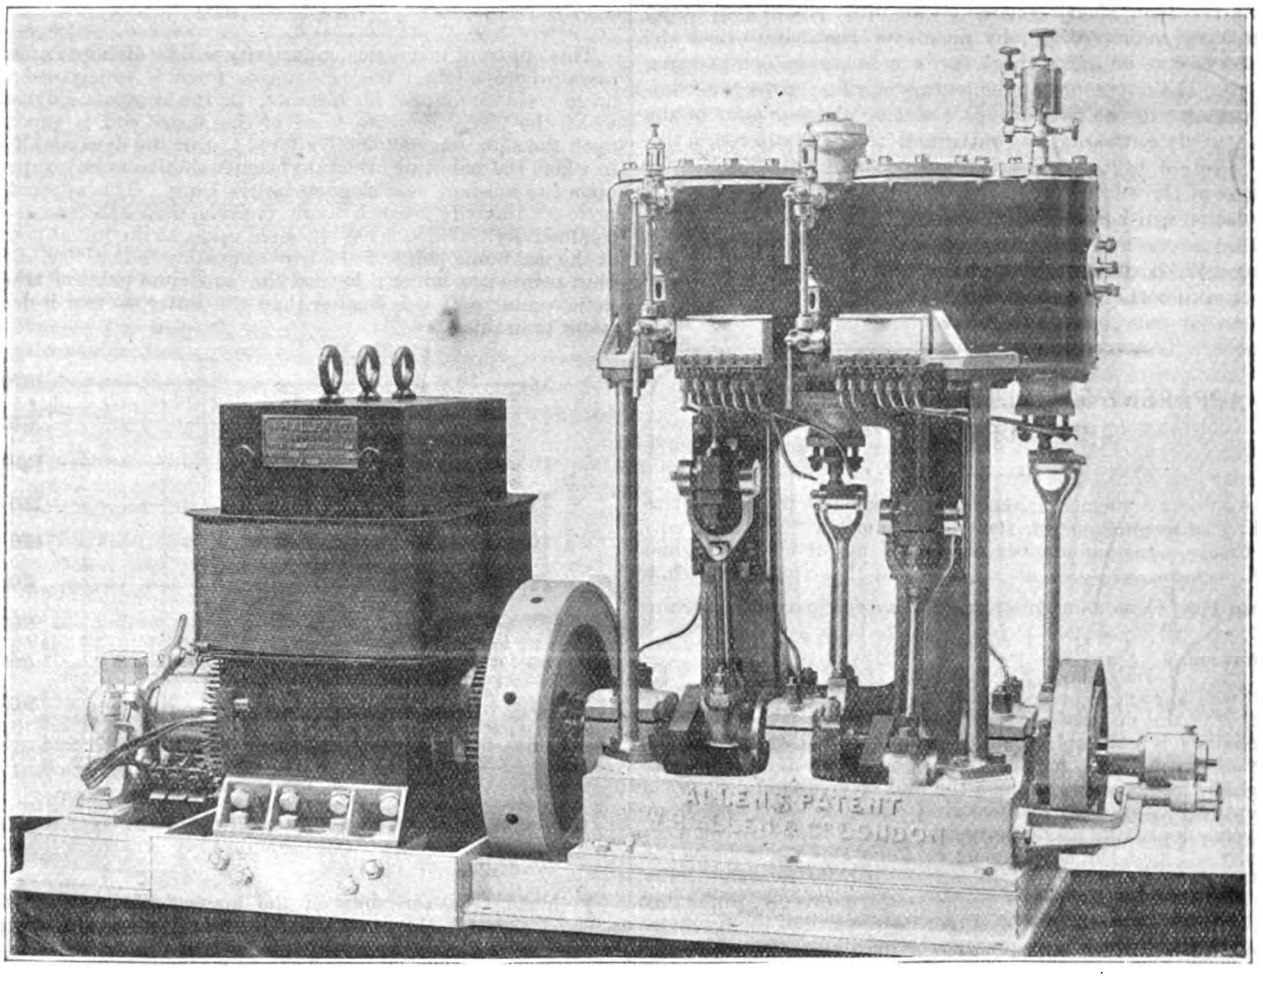
Digitized by Google

as they do when the discharge of the oscillator takes place in air; that is to say they gave the wave length peculiar to the resonator employed.

Oil carbonises and loses its transparency, but if two litres are employed, as was the case with us, there is no perceptible heating. The impairing of the liquid does not affect the intensity, even when working the apparatus for more than 20 minutes. This fact, when compared with the rapid diminution of effect in air, which has to be remedied by frequent cleaning of the terminals, is a decided advantage. We have also used essence of turpentine and petroleum and obtained analogous results. When using these liquids, however, and especially when using petroleum, a sort of bubbling takes place between the spark and the surface, which might possibly give rise to an explosion. It follows from these first experiments that oil is preferable.

ALLEN DYNAMOS AND ENGINES.

Two engines and dynamos have been recently supplied by Messrs. W. H. Allen and Co. for the Deptford central station of the London Electric Supply Corporation. The larger, when running at a speed of 200 revolutions per minute, has an output of 80 volts 500 amperes, and is driven by a compound engine, having cylinders 9½in. and 16in. diameter by 11in. stroke, the steam pressure being 100lb. The armature of the dynamo is drum-wound, with 104 laminated bars, and has a resistance when warm of 0·005 ohms. The core itself is constructed of charcoal iron discs, 25 mils. thick, insulated with paper, having a diameter of 18in. The field-magnet is shunt-wound, with 34,000 ampere turns. In order to secure an even distribution of the magnetic lines within the air-gap, the polar edges furthest away from the yoke are brought somewhat closer together than the upper polar edges, and by this means any excessive magnetic pull on the armature in an upward direction is neutralised. The current is collected by five 1¾in. gauze brushes off a commutator solidly constructed of hard drawn copper and plates of mica. The smaller machine, which we illustrate, supplies 300 amperes, also at a pressure of 80 volts when running at a speed of 250 revolutions, and is in general of similar make to the larger machine, being driven by an engine having cylinders 8½in. and 14in. in diameter with an 8in. stroke. The armature is 15½in. in diameter and is wound with 132 bars, its resistance when warm being 0·01, while that of the field is 5·5 ohms. By means of two gun-metal angle brackets forming an insulating base to the poles of the magnet the axis of rotation is kept low, whilst the distance between the iron of magnet and the iron of bed-plate is maintained at a normal distance of 6in.



Allen Combined Engine and 24-unit 80-volt Dynamo.

The arrangement of the cylinders of the engines forms the subject of one of Messrs. W. H. Allen and Co.'s patents; by it the steam passes from the high-pressure to the low-pressure cylinder over the top of the central piston valve, which at the same time regulates the compression of the high-pressure cylinder, and the exhaust of the low-pressure; the passage of the steam is thus made as direct as possible through short ports, and great economy is secured in the steam consumption. A central oil-box enables all the working parts to be lubricated from the single reservoir, a detail which is of considerable convenience in cases where continuous running is required.

Digitized by Google

The engines are in each case controlled by a flywheel governor, which automatically regulates the amount of steam admitted to the cylinders. When the whole load is thrown off the dynamo the governor has such complete control over the engine that the instantaneous increase of speed as read on the tachometer, or of the voltage as read on the voltmeter, does not exceed 25 per cent., and this is immediately brought down to an increase of 3 per cent., which forms the actual range of speed when the load is gradually removed. The speed of the engine can be regulated by means of a hand-wheel whilst running. Within the flywheel are two pivoted weights. Round a pin in the centre of each is passed a chain; this chain is taken round two pulleys so as to change its direction at right angles, and finally round a central shackle on the axis of rotation. Concentric with the axis are fixed two spiral springs, and as the pivoted weights move outwards by centrifugal force the springs are compressed by a plate attached to the central shackle. Of the two springs the outer is enclosed within a revolving sleeve centred on an inner sleeve containing the inner or main spring; by means of the hand-wheel the outer sleeve can be moved backwards or forwards, compressing or relaxing the outer or supplementary spring; thus the combined strength of the two springs, resisting the tendency of the weights to fly outwards by centrifugal force, is altered, a different position of the eccentric ensues, and in consequence the speed of the engine is altered. Full details of this method of regulation will be found in Messrs. Allen's patent No. 10,305 of 1891.

Messrs. W. H. Allen and Co. have now supplied a group of five exciters for the Deptford Central Station.

APPARENT MAGNETIC RESISTANCE AND CONDUCTIVITY.*

BY CHAS. STEINMETZ.

If we subject a magnetic circuit of any kind to a magnetomotive force F, this magnetomotive force F produces a "magnetic current," that is, a certain number of lines of magnetic force M, and as the *magnetic resistance or reluctance* of the circuit we define the ratio $P=\frac{F}{M}$; as its magnetic conductivity or permeability, the inverse value, $\mu=\frac{1}{P}=\frac{M}{F}$.

As is well known, in magnetic circuits consisting wholly or partly of iron, &c., the magnetic resistance P and hence the magnetic conductivity μ is a variable quantity, and depends largely upon the density of the magnetic current; that is, upon the number of lines of magnetic force passing through the unit of cross-section.

No entirely satisfactory mathematical equation being known for the dependence of the magnetic resistance, and therefore the magnetic current, upon the magnetomotive force, this dependence has for practical use to be plotted in curves; usually in such a way that the abscissæ represent the magnetomotive forces F, preferably in ampere-turns per centimetre or per inch length of the magnetic circuit, while the ordinates represent the magnetic current density in kilolines per square centimetre, or per square inch, as shown in curve I. of the accompanying diagram.

The magnetic conductivity has a simple geometrical meaning in the characteristic magnetic curve also. Connect any point x of the curve I with the starting point o, then the tangent function of the angle ϕ between this line x o and axis of abscissæ o A is the magnetic conductivity at the point x:

$$\mu=\frac{M}{F}=\tan\phi=\tan x\,o\,A.$$

This allows us to survey the variations of the magnetic conductivity μ by following the radius vector o x, when x travels on the characteristic curve from its starting point to saturation.

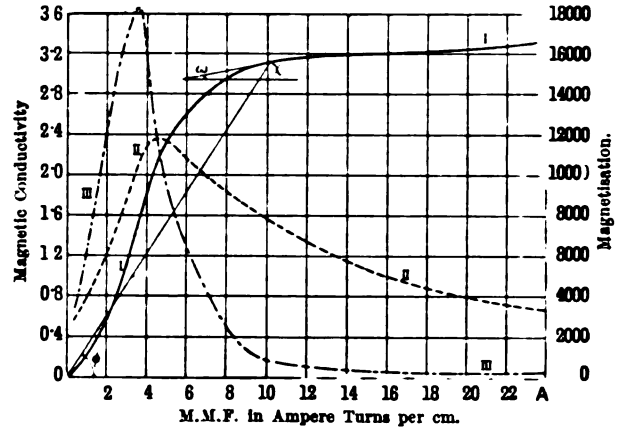
We see that the magnetic conductivity is first a minimum, $\mu_0=\tan\phi_0=500$, and then increases up to a maximum, $\mu^1=\tan\phi^1=2{,}320$, for the tangent point of the tangent drawn from o upon curve I.; and then decreases again, reaching 640 for the magnetomotive force F = 24. This value of the tan ϕ has been plotted in curve II., the susceptibility curve, and shows plainly the rise up to a maximum, and then the decrease again.

But we derive still another tangent function from the magnetic characteristic. In drawing at any point x of the curve I. a tangent to this curve, this tangent forms an angle ω with the axis of abscissæ, or with any other horizontal line. The tangent function of this angle ω is what I call the *apparent magnetic conductivity at the point x*. This apparent magnetic conductivity is often of even greater importance than the true magnetic conductivity. It is the magnetic conductivity which a magnetomotive force meets when acting upon a magnetic circuit magnetised already up to the point x by another magnetomotive force.

Let, for instance, a magnetic circuit be magnetised by the magnetomotive force F = 6 ampere-turns per centimetre, which produce the magnetism M = 12·95 kilolines, per square centimetre. Introducing now in this magnetic circuit a further magnetomotive force of $f=1$ ampere-turn, this magnetomotive force, superposed upon F, will either increase or decrease, according to its direction, the magnetism M produced by F, to 13·08 or 12·82 kilolines respectively; that is, the magnetomotive force $f=.1$ will produce an additional magnetism, $m=.13$, superposed upon the magnetism M = 12·95, caused by F = 6, and hence the magnetomotive force f will meet with an apparent magnetic conductivity of $\delta=\frac{m}{f}=1{,}300$, while the true magnetic conductivity at this point is:—

$$\mu=\frac{M}{F}=2{,}160.$$

This apparent magnetic conductivity will be of importance in all cases where another magnetomotive force is superposed upon a magnetised circuit, as, for instance, in the compound dynamo, in which the magnetomotive force of the series coil is superoposed upon the shunt magnetomotive force; or in the dynamo alternator in which the pulsating armature magnetomotive force is superposed upon the constant field magnetomotive force. This apparent magnetic conductivity is much more variable than the true magnetic conductivity. Twice it has the same value, at the initial point, and at the maximum point of the true magnetic conductivity. Between both points it is larger; beyond the maximum point of true magnetic conductivity it is smaller than the latter, so that it decreases faster than this does.



I., Magnetisation; II., Magnetic Conductivity, μ; III., Apparent Magnetic Conductivity, δ.

Following the variations of the tangent of the characteristic curve I., we see the apparent magnetic conductivity—plotted in curve III.—start at the same point, 500, as curve II., but rise very rapidly up to a maximum value of 3,700, for the magnetisation M = 7·25 corresponding to a M.M.F., F = 3·5, then decrease again just as rapidly, intersect II. at 2,320, and rapidly decrease to 100, for F = 12, then decreasing very slowly down to 40, for F = 24. It is interesting to note that at about 2·5 ampere-turns the apparent conductivity is more than twice as large as the true conductivity, while at about 14 ampere-turns the apparent conductivity is already less than one-fourteenth of the true conductivity.

Of still more importance than for the design of continuous-current dynamos is the consideration of the apparent magnetic conductivity in alternating-current dynamos. For in the alternator the armature reaction upon the field is well known to be usually much larger than in the continuous-current dynamo, because of the very sudden fluctuations of the armature magnetism. At the same time, for the constant potential alternator a small armature reaction is of more importance even than for the continuous-current dynamo, because the alternator has, besides the drop of potential due to armature resistance and to self-induction, still another cause for a drop of potential with increasing load, which the continuous dynamo current has not. Now, every time that an armature coil passes in front of a field pole, the current flowing at this moment in the armature coil, throws a magnetomotive force into the magnetic field circuit, which is magnetised by the exciting current. In consequence

* From the *Electrical Engineer* of New York.

Digitized by Google

thereof, the magnetic field circuits are acted upon by two magnetomotive forces, namely, the magnetomotive force of the exciting current, which is supposed to be constant, and the fluctuating magnetomotive force of the armature current. This latter magnetomotive force, if of considerable influence, will not only cause the field magnetism to fluctuate also, and to be a minimum, where it is needed most for inducing electromotive force—thereby changing the shape of the current wave from the true sine shape to a more ragged appearance—but this fluctuation of the field magnetism will induce an alternating electromotive force in the exciting circuit, which, besides causing the exciter dynamo to spark, wastes quite a considerable amount of energy.

From what has been said it is obvious that, to keep the fluctuations of the exciting current of an alternator down as much as possible, the field magnets have to be magnetised up to that point of the magnetic characteristic, at which the apparent magnetic conductivity is very low. For instance, employing iron of the characteristic shown in the diagram, when magnetising the field with a density of 15,000 lines of magnetic force per square cm, in spite of the larger number of exciting turns the fluctuations of the field current will be reduced to about one-twelfth the value they have when the field is magnetised with 8,000 lines per square cm. The fluctuation of the field magnetism will even be reduced still more. In practice, indeed, these fluctuations of the exciting current are somewhat decreased in many cases by eddy currents set up in the field iron. But to rely upon eddy currents in the iron is certainly anything but an economical way of dynamo building.

REVIEWS.

Chemical Theory for Beginners. By LEONARD DOBBIN, Ph.D., and JAMES WALKER, Ph.D., D.Sc. (London: Macmillan and Co.)

The authors state in their preface that their object has been to assist beginners in obtaining an elementary knowledge of the principles upon which modern chemistry is based, and they may be congratulated on the success of their attempt to write a book which shall serve as an introduction to the writings of Mendelejeff, Lothar Meyer, and Ostwald, and at the same time be comprehensible to the beginner. The smaller textbooks usually treat theoretical matters so lightly that the student has small opportunity of obtaining any satisfactory grasp of these during the earlier portion of his studies; while in the larger treatises the same subjects are not dealt with very fully, because the student is supposed to have been introduced to them already. Chemical formulæ are the outcome and embodiment of many facts and theories, and therefore their full significance can be appreciated by the more advanced student only, although their use is necessitated at a very early stage. In this book the nature of the facts on which the theories are based are clearly set forth, and as the experiments have been carefully selected, the student who works through these should find little difficulty in following more advanced treatises. It will probably surprise many to find the modern theories of electrolysis, mass action, and dissociation introduced into a work which purports to be of an elementary character, but since Arrhenius in 1887 developed the Clausius hypothesis and brought it into the quantitative form which is now called the theory of electrolytic dissociation, so much work has been done on the subject that many, besides beginners in chemistry, will be glad of a succinct, non-mathematical account of the views which are now attracting so much attention, and of the reasons for them. The practical applications of electrolysis are daily extending, and with the increase of our knowledge of the conditions under which electro-chemical reactions take place, we may expect a still more rapid extension; and therefore a work of this sort is to be commended which opens to the general reader a branch of science that is usually regarded as a preserve of the mathematician.

Die Elektrischen Accumulatoren und ihre Verwendung in der Praxis. By J. SACK. (Wien: A. Hartleben.)

This book is interesting as the work of a telegraph engineer, since it calls attention to a wide field for the employment of secondary batteries, too apt to be overlooked, although they have been employed by the British authorities almost since their first introduction commercially, and many of the early pioneers in the development of the secondary cell were telegraph men. The arrangement of the book follows the natural development of the cell, that is to say, a brief summary of the early experiments on polarisation effects noticed by Ritter and others is given, followed by a short description of the leading batteries up to the time of Planté. The theory of the Planté cell is then discussed, and the principal modern developments of the accumulators are dealt with. There is a good chapter on the various methods which have been suggested from time to time for the automatic regulation of charge and discharge, and there is also a summary of the more important uses to which the cells have been, or might be put, with the best arrangement for the various purposes. There are numerous illustrations.

Notes on Design of Small Dynamo. By GEORGE HALLIDAY. (London: E. and F. N. Spon.)

Although the small dynamos described in this book are little else than toys, the principles of their construction are discussed with care and in a very methodical manner. The author feels the want of names for magnetic units. Instead of contenting himself with an explanation of the mode of measuring and expression of the strength of a magnetic field, he must needs name the unit. Finding the symbol H to hand, he coins the word "Hop." As an example, we read on p. 36, "Find the ampere turns necessary to produce ·0000115 Hops per square inch in a cast-iron circuit 12 inches in length and 4 square inches in area." This might just as well have been written, "Find the ampere turns necessary to produce a field of ·0000115 per square inch," or "a field of a strength of ·0000115 per square inch," &c. In any case the reader must note the way in which the author proposes to measure the strength of field. Without any explanation that we can find, and there is no index to assist the search, the name "kapp" is used apparently to denote the same unit as a "Hop." One is about as bad as the other, and there is an invidious use of a small initial letter in one case, and a capital in the other. "Why be-little pioneers?" The chapter on the bearings of dynamos savours too much of the lecture-room; not a word is said about the side pull of the magnets on the armature.

Inter-Communication in Railway Trains; Means of Communication between Intermediate Places and Stations; Means of Communication between Trains while on the Journey. Papers by H. POLLITT, read before the International Congress on Railways at St. Petersburg, June, 1892.

These three Papers, by Mr. H. Pollitt, of the Manchester, Sheffield and Lincoln Railway, contain descriptions of the many ingenious mechanical and electrical appliances which are in use in railway work. The first of these, dealing with methods of communication between the passengers and the staff in charge of the train, discusses the cord, electric, and mechanical or pneumatic systems. The author finds that the electrical methods are liable to defects arising from the numerous contacts and surfaces which are very seldom used.

The second Paper, which is copiously illustrated, gives a brief and rather scant account of block signalling, mechanical interlockings, electric signalling, telegraphy and telephony. Much of it is so sketchy as to be of little use or interest; the illustrations are by far the best part of the work.

The third Paper describes two methods of telegraphing to or from a moving train, one by means of a trailing contact on an insulated rail, and the other by induction. Both systems appear to have been used with considerable advantage in America.

Spon's Engineers' and Contractors' Illustrated Book of Prices. 1892-3. (London: F. and N. Spon.)

This large and handsome volume is the outcome of a praiseworthy attempt to collect a great number of price-lists and catalogues into a convenient form. An index of subjects and one of names is provided. As far as it goes, this collection is very useful, but only about 112 firms are represented. We hope that the publishers in re-issuing this book will suppress a large portion consisting of mere advertisements, which contain very little information, and will collect together a larger variety of really useful price-lists. The matter does not appear to be classified in any way, as has been done in similar publications for other trades.

MAGNETIC LAG AND HYSTERESIS.

By degrees, and thanks to purely experimental research, we are becoming acquainted with the magnetic properties of iron, and it may be noticed that all the work which has been done has been of a purely scientific character although the results are of great commercial importance. Iron has been tested for commercial purposes and instruments have been made to facilitate such tests, but up to the present the researches have been carried out with little or no reference to trade considerations. The permeability of iron was recognised as a matter of importance as soon as dynamo building became a branch of engineering, but the hysteresis losses, though of some importance in the armatures of continuous current machines, were not carefully attended to until alternate current dynamos and transformers became common. We publish in this issue an account of an investigation by Messrs. EVERSHED and VIGNOLES on the core losses occurring in transformers. This comes opportunely in connection with Dr. HOPKINSON's Paper on this subject printed in our issue of September 9, since it offers a very likely explanation of the differences, there described, between the hysteresis curves obtained with slow and rapid magnetic cycles. The present Paper is further important, as it appears to dispose of the question of magnetic lag, by showing when, and to what extent, this phenomenon occurs, as far as transformers are concerned. It is evident, from the results given, that the fact is of negligible importance, although as time-lag affects the hysteresis curve to some extent when the magnetism is changed slowly, the hysteresis constants obtained by slow cyclic experiments cannot be considered quite applicable to alternate current work. The slight time-lag which occurs at high frequencies, however, produces an effect which is in the opposite direction to what has usually been supposed, for the lag tends to decrease the loss of energy and, as the phenomenon is more important the slower the cycle is performed, the

Digitized by Google

hysteresis loss becomes greater as the frequency is increased. The result may perhaps be best summarised by stating that the hysteresis loss in a cycle is constant for all high frequencies, that it is slightly less for very low frequencies; and that when a single cycle occupies some minutes, the loss may be diminished by as much as 20 per cent.

The magnetic-lag phenomena which occur with slow cycles, although of no importance from an engineering standpoint, is of considerable theoretical interest, and deserve further investigation. It seems remarkable that an effect of this kind which increases the area of the hysteresis curve by as much as 20 per cent. should have so long escaped notice, but a simple explanation at once offers itself. Hitherto these curves have been obtained by the static method in a symmetrical manner, the magnetising current being reversed in order to get the negative part of the curve. Messrs. Evershed and Vignoles do not, however, reverse the current, but use a subsidiary current to supply the negative magnetising force. The experiments, instead of starting from the middle of the curve, as hitherto, always start from one of its extremities. This method was described by Mr. Evershed in the course of the discussion on Dr. J. Hopkinson's presidential address before the Institution of Electrical Engineers, but the use of the constant current was not clearly understood at the time. A brief discussion, which is not recorded in the Journal of the Institution but which was alluded to in our report of the meeting, took place on this point. Profs. Ayrton, Perry, and S. P. Thompson could not elicit, either from Mr. Evershed or from Mr. Vignoles, who came to his assistance, the object of using two magnetising circuits. Since then, however, the method has been clearly described in the article by these authors, which appeared in *The Electrician* of October 16, 1891, and of which their present contribution is the sequel. Mr. Evershed alluded to the results which they had obtained in the course of the discussion which followed Mr. Alex. Siemens' Paper on February 25th, 1892, but he did not enlarge upon them, as an early publication of their work was intended. But on April 8th, 1892, we printed an article by Prof. J. J. Thomson on the heat produced by eddy currents, and Messrs. Evershed-Vignoles found that his final result for currents in a thin plate was four times greater than theirs. It remains to be seen where the discrepancy arises, but in the meantime, after delaying publication for several months, their experimental work has been confirmed, and we hope that, as on the former occasion, these authors will be able to hold their own. The apparatus used by the experimenters was very small, the over-all dimensions of the transformer being about four inches, but the phenomenon under investigation merely depended on the frequency and the induction density, and could be most conveniently tested with small apparatus. The object was not, as in the experiments of Mr. Mordey and many others, to examine the action of a transformer, but to test the properties of iron; and it is to be observed that we here have a full account of careful tests by two different methods on the same piece of iron.

Much more commercially important than the effect of magnetic lag is the observation of the authors that two samples of charcoal iron obtained from the same mills, sold as the same quality, and having the same permeability, may differ in their hysteresis losses by more than 70 per cent. from each other. This serves to explain the widely diverging results of tests of this material published by Messrs. Ewing, Siemens, Dobrowolsky, and Hopkinson. The conclusion seems to be that published tests of hysteresis losses, however carefully the experiments may have been performed, cannot be relied upon as being applicable to other samples of the same nominal quality. In our review of Prof. S. P. Thompson's "Dynamo-Electric Machinery" it was suggested that a word of warning might have been introduced against the use of mild steel, and Mr. Kapp wrote to ask why mild steel should be avoided. As was then explained, mild steel was not impeached, but the description was so vague, that very undesirable qualities might be included by the iron merchant, without any thought of the consequences. It appears now, that even charcoal iron is liable to the same differences in magnetic quality, and if this be the case, it becomes a matter of the highest importance that chemical analyses be made, and the real causes of difference traced. In the absence of further information which would be difficult to obtain, there is a strong probability that real charcoal iron has small hysteresis, and that the minute contaminations which mild steel is liable to absorb during its manufacture, and which are disregarded because they do not sensibly affect the mechanical properties or indeed the permeability, may give rise to serious residual magnetism. We understand that in America iron manufacturers find it is worth while to cater for the requirements of dynamo and motor builders, but these two trades are of a very different relative importance in this country, and the right quality could be more easily obtained if electrical engineers could describe their wants in ordinary metallurgical terms.

THE MEASUREMENT OF HYSTERESIS AND EDDY-CURRENT LOSSES IN TRANSFORMERS.

BY SYDNEY EVERSHED AND ERNEST B. VIGNOLES.

II.

In our first article* we have described a method by which the loss of power in the core of a transformer may be measured by the rise of its temperature; and the first application we made of it, namely, to determine whether a cross-induction, applied to an alternately magnetised ring, diminished the loss by hysteresis, gave such exceedingly concordant results as to enable us to determine within very narrow limits the waste of energy in an iron core; and we therefore determined to use the method for a preliminary investigation of the subject of viscous hysteresis.

This is a subject which has long engaged the attention of physicists, but we found the current ideas on the subject in a somewhat nebulous condition. Profs. Ayrton and Perry, in their Motor Paper of 1883, came to the conclusion that they had distinct evidence in the displacement of the field in a motor, of the existence of viscous hysteresis to a very appreciable extent; and to this view they have always adhered. Others, however, have denied the existence of viscous hysteresis of an appreciable amount, explaining the Professors' results as effects of armature reactions and eddy currents in the core.

The first evidence which was published on the subject, so far as we know, was the experiments of that indefatigable worker in this field, Prof. Ewing, who showed that when iron was subjected to weak magnetising forces, the amount of induction continued to increase for some minutes after the application of the force.

But before this, other experiments on this subject had been made by Mr. C. J. Barley at the Central Institution, in which a ring of iron was rotated above the poles of an electro-magnet in the field of which a permanent magnet hung with its poles immediately over the rotating ring. Eddy currents were eliminated as far as possible by lamination, and air currents by suitably screening the suspended needle; and the result was to show that in addition to the displacement in the field caused by static hysteresis when the ring was slowly turned, there was a further displacement in the same direction when the ring was rotated at speeds corresponding to a frequency of about 100 $\sim$ per second or more; and Mr. Barley attributed this to viscous hysteresis. The experiments do not appear to have led to quantitative results, and can hardly be regarded as conclusive.

* *The Electrician*, Vol. XXVII., No. 664, October 16, 1891.

Digitized by Google

Theoretically it would appear probable that as even molecules must have some inertia, time must be taken to move them; but it was obviously a question whether in a transformer worked by an alternator at, say 100 ∿ per second, the time taken for the induction to pass from zero to its maximum value—about 1/400 of a second—was enough to make a serious difference in the amount of induction produced by a given magnetising force.

Prof. Ryan, whose curves from actual transformers would have been the most valuable practical contribution to the subject ever published, had he given full details and dimensions of the transformers used,* gave in his Paper a curve of losses in his iron in which eddy currents were included with hysteresis. This curve may be seen in the articles on Transformers by one of the authors in *The Electrician*;† and Prof. Ryan, comparing this curve with Ewing's, concluded that there "was no room for viscous hysteresis." He however appears to assume that his iron was identical in quality with that tested by Prof. Ewing, a somewhat unwarrantable assumption, as we shall presently show.

Such was the state of our knowledge of the subject when in March, 1891, we made a discovery which gave us some hope of finally settling the question.

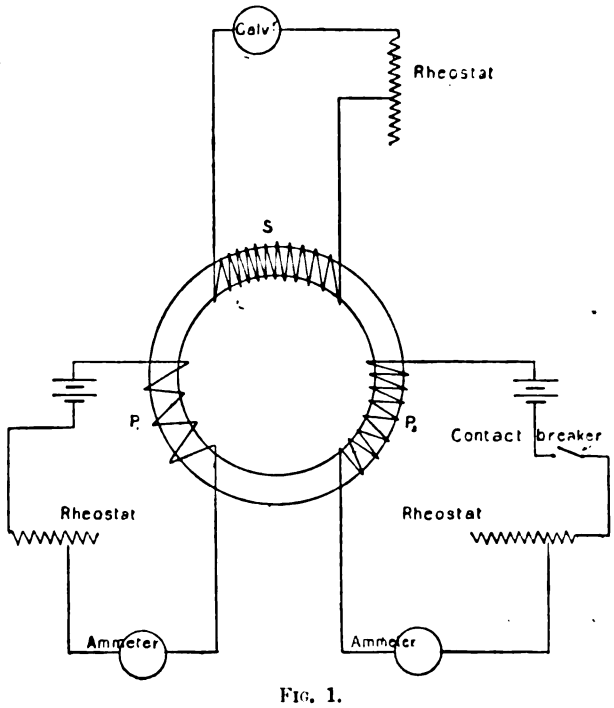

Fig. 1.

In order to explain this clearly, it is necessary to refer to the Paper read by one of the authors in May, 1891, to the Old Students' Association of the City and Guilds of London Institute.‡ A very full description of our method of testing iron is given in this Paper, to which we may refer any one who cares for fuller information. Briefly the arrangement is this: The ring of iron is wound with two superposed primaries, in one of which, P_1 (*see* Fig. 1), a constant current is maintained; in the other, P_2, a magnetising force is produced in the reverse direction; so that by making and breaking this circuit the iron can be carried practically instantaneously through an induction cycle, starting from and returning to the lowest point of the curve. Now by consulting Fig. 2 it will be seen that observations on the rising curve can be taken by simply making a current in P_2, thus obtaining the ordinates AB, CD, &c.; and since our galvanometer takes about one second to make its swing, its period being 3·8 seconds, it follows that all the observations on the *rising* curve give the *integral of the Induction up to one second after the application of the magnetising force.*

Not so with the falling curve. In order to get on to this curve, it is necessary to put on the current P_2 at its maximum value, decrease to the value required, wait to read the ammeter (these operations taking perhaps half a minute), and then *break*.

Consequently if the induction lags in time behind the magnetising force, it has time to *creep down* during these processes, and we should naturally expect it to creep most at the steep parts of the curve; therefore, the net result should be a difference in shape between the rising and falling curves; the falling curve being more perpendicular to the axis of H than the other, and enclosing less area. This consideration was forced upon us by

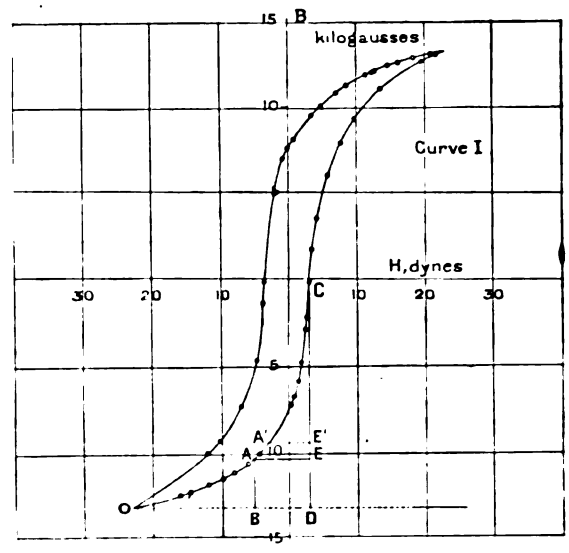

Fig. 2.—Method of obtaining Ordinates of Cyclic Curve.

the study of our curves, in many of which this phenomenon is most noticeable. In the Paper read to the Old Students' Association, already referred to, the cause was hinted at; but as we then had no further evidence, we had not the confidence in the explanation which we now possess.

The difference between the work done if the induction were forced through its cycle in about two seconds, and that which

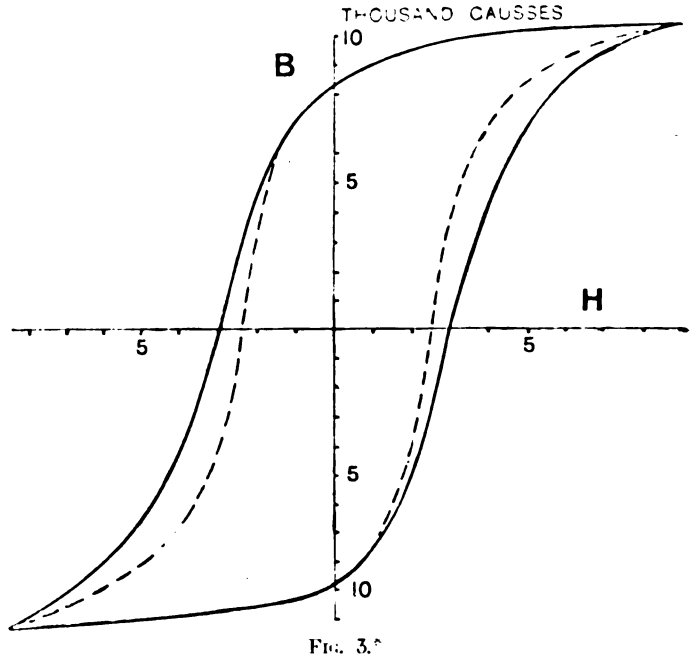

Fig. 3.*

would be done if the time taken were very large is considerable. The curve given here, Fig. 3, is a good instance. The full line is the curve when the integral of the induction up to one second after the application of the magnetising force is taken as the ordinate, while the dotted line shows the area

* Why *do* people invariably leave out the most essential information?

† Vol. XXVI., p. 724, April 17, 1891.

‡ *The Electrician*, Vol. XXVII., p. 50, May 15, 1891.

*As no names have yet been given to the units, we have been compelled to invent our own:—

1 Thom = 1 C.-G. S. unit of induction.

1 Gauss = 1 Thom per sq. cm.

Digitized by Google

when a comparatively long time, perhaps half a minute, is allowed to elapse between the application of the force and the measurement of the amount of induction. The difference in the areas amounts to 19 per cent. of the smaller curve. It will be understood that this particular curve is an extreme case; but it is noticeable that all our curves give losses larger than those given for similar materials in Prof. Ewing's tables.*

All curves except ours have been taken by static methods† which would give the area of the dotted curve; and if the difference between the work done in the two cases mentioned is so great, why should it not be far greater when the time occupied is only $\frac{1}{100}$th the part of a second? Indeed it seemed highly probable that the difference might be very considerable, and preliminary experiments had led us to anticipate that a difference of 50 per cent. was not unlikely. Obviously to determine the point it was necessary to measure the power wasted when the transformer was run on an alternating current, and compare it with the loss when put through the same cycle comparatively slowly.

That such a comparison is not without commercial value the following considerations will show. The number of lamps on the circuits of the alternate current supply companies in London alone must exceed the equivalent of 120,000 thirty-watt lamps. The transformers running these are mostly small in size, and it takes at least 5 per cent. of their full load output to excite them; hysteresis losses being responsible for 80 per cent. of this. The money value of this power—170 units per hour—to the supply companies, cannot be less than £10,000 a year, money which is being absolutely thrown away, and any inquiry into the causes of this waste cannot but be of commercial importance. Observe that in this calculation the efficiency of the transformers has been based on the assumption that the *static* curve gives the hysteresis loss; it follows, therefore, that if there were an additional waste amounting to anything like 50 per cent., another £5,000 at least would have to be added to the above figure. But, apart from this, the question is one of considerable scientific interest.

We will now proceed to describe the experiments by which the point may be settled. The first and most satisfactory method is the use of a watt-meter. If the back electromotive force of the pressure coil is kept very low, and no metal in any part of the instrument is allowed to produce eddy current errors, the method is, of course, perfectly accurate. Such a watt-meter, however, takes time to construct, and we were impatient to have some information on the subject; we therefore determined to make preliminary experiments by the thermometric method.

The process was as follows: The actual rate of rise of temperature, corrected for cooling, was determined, and then compared with the rise predicted from the following data:

(1.) The area of the B.H. curve taken from the actual piece of iron used.

This gives the watts spent in hysteresis, when the iron is going through its cycle once in about two seconds.

(2.) The watts spent in eddy currents in the iron from the mean induction density. This waste is so small compared with the amount of energy lost by hysteresis that no elaborate mathematical treatment is required.

From 1 and 2 we get the rate of conversion of energy into heat.

The specific heat of the transformer should also be determined, and we are then in a position to predict the rate of heating—when no cooling takes place—and on the assumption that the area of the B.H. curve is the same for such widely different frequencies as 100 $\sim$ per second and 0·5 $\sim$ per second. Any difference between predicted and observed effects may be set down to viscous hysteresis.

The Transformer.

The transformer was built up of twenty charcoal-iron circular stampings, the inner diameter of which was 4·15cm., outer diameter 9·25cm. The mean thickness of each stamping from 40 measurements was ·0414cm. Embedded in the core thus formed was the bulb of a clinical thermometer, having a range of 10° – 35°C. in tenths of degrees, and capable of being easily read to 0·025°C.

A secondary circuit of 300 turns was wound evenly all round the ring for the purpose of measuring the induction in conjunction with a Cardew voltmeter. The primary winding consisted of one straight cable, on which the transformer was threaded, without touching it at any point. The idea of this precaution was to render the heating due to C^2R in this cable of as little importance as possible.

The following table contains complete dimensions, &c. worked out from the above data:—

Transformer.—

Area of section across induction path	= 2·12 sq. cm.
Average length of induction path.....	= 21·02 cm.
Volume of iron	= 44·55 cc.
Weight of transformer including secondary	= 377 grammes.
Secondary circuit	– 300 turns.
,, resistance	= 7·5 ohms.
Resistance of Cardew voltmeter	= 55 ohms.
Effective E.M.F. in secondary circuit	= Reading of Cardew $\times \frac{(55+7\cdot5)}{55}$

Measurement of Specific Heat of Transformer.

Since the specific heat of iron is known to lie between 0·11 and 0·12, it was easily determined with sufficient accuracy in the following manner:—The transformer was heated to 100°C., and the total rise of temperature produced by immersing it in a vessel containing a certain weight of water at a known initial temperature, was compared with that produced by a known weight of boiling water when mixed in the same vessel with the same amount of cooling water at nearly the same initial temperature. Since we know that somewhere about 0·11 of the weight of transformer must be the weight of the water added to obtain the same rise of temperature, the two experiments are easily made practically identical as regards cooling; the same vessel being used and the air temperature being constant.

The transformer, being built of iron plates insulated with thin paper, naturally carried over from the bath in which it was heated a considerable amount of water; and it is in the weight of water occluded that the greatest chance of variation occurs. Several measurements, however, showed that the variations in weight, on lifting the transformer from the water bath, were within the limits of accuracy required.

Put algebraically, if

w = weight of dry transformer,
v = ,, ,, water occluded,
W = ,, ,, ,, in cooling vessel,
g = ,, ,, ,, used for comparison in second experiment.
x = specific heat of transformer,
y = ,, ,, ,, water,
T = initial temp. of transformer, i = ,, ,, ,, bath ..... } in Expt. I.,
t = final temp. of iron and bath
T = initial temp. of water used for comparison, J = ,, ,, ,, bath ..... } in Expt. II.,
θ = final temp. of both .....
q = heat lost by radiation and convection from bath,

then the equation

Total heat before immersion = total heat after immersion + quantity lost, or—

$$wx\mathrm{T} + vy\mathrm{T} + \mathrm{W}yi = wxt + vyt + \mathrm{W}yt + q. \quad . \quad (1)$$

represents the result of the first experiment, the second experiment being of course necessary to eliminate q.

The corresponding equation for the second experiment is—

$$gy\mathrm{T} + \mathrm{W}yj = gy\theta + \mathrm{W}y\theta + q \quad . \quad . \quad . \quad (2)$$

Since the conditions as to cooling during the rise of temperature of the bath are practically identical, no appreciable error can be caused by assuming the quantity of heat lost, q, to be the same in both experiments.

Eliminating q from equations (1) and (2), and writing $y=1$ we find the value of specific heat of the transformer compared with water, viz. :—

$$x=\frac{W(t-i)+g(T-\theta)-W(\theta-j)-v(T-t)}{w(T-t)} \quad . \quad (3)$$

Substituting the following values in this equation :—

W = 10,630	grains	T = 100°C.
g = 1,080	„	i = 12·7°C.
v = 675	„	t = 21·4°C.
w = 5,815	„	j = 12·2°C.
		θ = 19·3°C.

we arrive at the value

$$x = 0{\cdot}112 \text{ gramme-degree-centigrade.}$$

Remembering that 4·2 joules = 1 gramme-degree-centigrade, we find the specific heat of the transformer to be

$$4{\cdot}2 \times 0{\cdot}112 = 0{\cdot}47 \text{ joules.}$$

It is evident, therefore, that the insulating tape and paper and the copper secondary circuit have practically no effect on the value of the specific heat, which is generally given in text-books as 0·112 for soft iron.

The transformer was then taken to pieces, dried, and rebuilt, Experiment I. having reduced it to a sloppy mass.

*Measurement of Waste of Power.**

The order of procedure was as follows :—Having previously calculated the volts on the Cardew which would be produced by a maximum induction-density of 10,000 gausses,† the primary current was started and raised as rapidly as possible to a value giving the required reading on the voltmeter. We may note that this adjustment must be made exceedingly quickly, as the range of the thermometer is short and the whole of the heating curve is taken in less than 10 minutes.

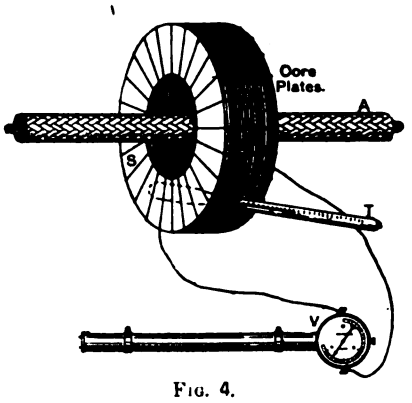

Fig. 4.

Observations are taken by two experimenters of the times at which the transit of the mercury over each degree of the scale takes place ; while a third keeps the speed of the alternator constant ; a small adjustment being made from time to time of the primary current as the circuits rise in temperature.‡ When the thermometer is about to reach the top of its scale, the primary and secondary currents are rapidly replaced by direct currents of the same effective value ; and time readings of the thermometer are taken as the transformer cools. As the rate of cooling depends on the difference of temperature between the transformer and the air, frequent observations must be made of the air temperature in the neighbourhood.

It may not be without interest to compare this method with other thermometric methods which have been used or proposed for the purpose. Mr. Mordey attempted to determine the final temperature, and to do this he had to maintain the power supplied to the transformer and the frequency constant for many hours, encountering additional difficulties in the variation of the temperature of the air and surrounding objects, accentuated by the use of a "shilling thermometer." Prof. Ewing, on the other hand, has suggested* the use of a thermo-electric couple in place of the thermometer, but we should anticipate difficulties from currents induced in the thermo-electric circuit. Mr. Alex. Siemens has recently published some measurements of the power wasted in a transformer core, determined from observations of two temperatures, giving two points on the curve corresponding to our curve J ; thus making a great advance on the somewhat crude method of observing final temperatures. The method we used, similar in principle, gives however ten or twenty points

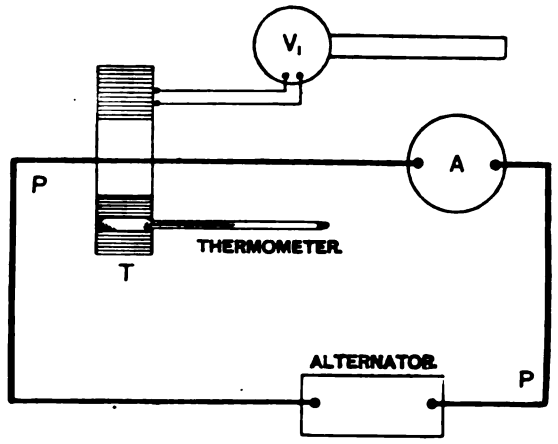

Fig. 5.

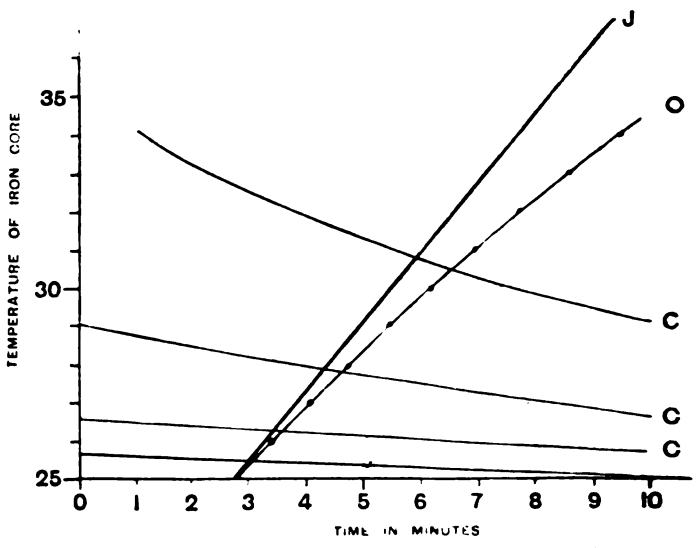
on the curve in the space of ten minutes, the discrepancy of these affording an excellent criterion of the accuracy of observation. Moreover, the use of an accurate thermometer gives the temperature without further complication, and it is much easier to determine a number of times by the observation of the transit of the mercury over successive divisions than by measurement of a series of resistances.

Fig. 4 is a perspective view of the arrangement we adopted, the circuits being arranged as shown in Fig. 5. The transformer in the present case is laminated in the plane of the ring, and not as shown in Fig. 5.



O. Observed rise of temperature. C. Cooling Curve. J. Corrected rise of temperature.

Fig. 6.—Curves showing Rate of Production of Heat in Iron Core.

The results of Experiment II. are plotted in Fig. 6 where O is the heating curve, C the cooling curve When the former is corrected for cooling in the manner described in our first article the curve J is obtained, indicating the rate of heating which would take place if no cooling occurred ; in other words, the rate of conversion of energy in the core of the transformer.

The power spent in the core (in watts) is obtained from J in the following manner :—Experiment I. shows that the work

required to raise 1 gramme of transformer 1°C is 0·47* joules.

Multiplying this into the weight of the transformer, viz. 377 grammes, gives 177 joules required to raise the transformer 1°C. The rise from curve J is found to be 0·0305°C. per second; and, therefore, the number of joules per second (watts) converted into heat is 177 × 0·0305; or *5·4 watts.*

GEARING.

BY E. TREMLETT CARTER.

(*Continued from page 561.*)

Flywheel Details.

We have seen in the last article that a flywheel must possess a certain moment of inertia, which is determined by the work it has to do, and that this moment of inertia can be obtained either by having a large mass of metal at a small radius or a less weight at a greater radius. It was remarked that in practice the radius of the rim is not allowed to exceed that value which would allow the rim to have a certain velocity when the engine was turning at its fastest rate. We have now to consider the reasons for these limitations, and why it is advisable to adopt certain rules in proportioning the parts of a flywheel.

If a weight is fastened to the end of a string, the other end of which is held in the hand, the weight being whirled round a circle at a rapid rate, one is conscious of a pull in the string which increases as the rate of revolution is increased or as the radius is diminished. The tension in the string, of which the pull on the hand is but one end, causes an opposite force on the weight. The hand is pulled away from the centre by a force which is called *centrifugal*, and the weight is pulled towards the centre by an equal but opposite force which is called *centripetal*. These two forces constitute a tensile stress in the radial link or string. Every part of a moving flywheel is placed under this tensile stress, and, since cast iron is a very weak and unreliable material when under tension, there arises the necessity for a high factor of safety in the design of this engine detail. We will consider firstly the stresses in the rim of the wheel, and subsequently those in the arms.

In Fig. 15 let the two concentric circles represent an element of the flywheel rim at a radius, r, moving with a velocity v ft. per second, and let b be the breadth of the rim. The rim is made of a material having a density Δ, and a strength per square inch equal to S; the whole mass of the circular element being called M. If we consider any small portion of the rim, subtending any angle $d\phi$ at the centre, and making an angle ϕ with the plane of any given section A B, we find that there is

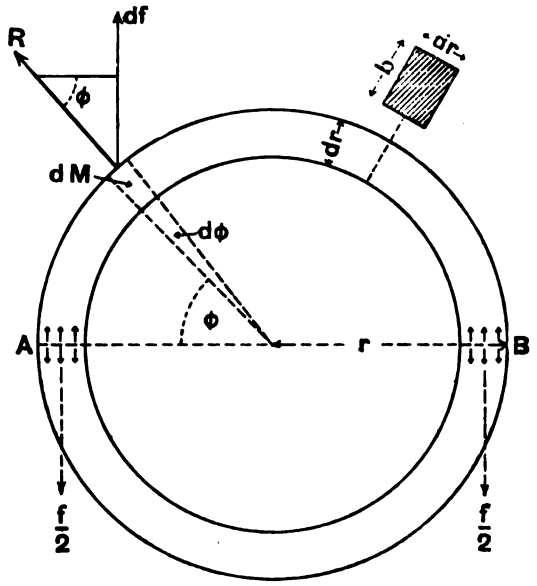

Fig. 15.

a force equal to R acting radially upon it, and that the component of this force at a normal to the plane of section is df, the integral of all the normal forces being f. Then,

$$R = dM \cdot \frac{v^2}{r},$$

and
$$dM = \frac{\Delta}{g} \cdot b \cdot r\,dr \cdot d\phi$$

Therefore,
$$R = \frac{\Delta v^2}{g} \cdot b \cdot dr \cdot d\phi,$$

therefore,
$$df = \frac{\Delta v^2}{g} b \cdot dr \cdot \sin\phi \cdot d\phi$$

and
$$f = \int_0^{\pi} \frac{\Delta v^2}{g} \cdot b \cdot dr \cdot \sin\phi \cdot d\phi = \frac{2\Delta \cdot v^2}{g} \cdot b \cdot dr.$$

Now the section placed under this stress is equal to

$$\text{area} = 2\,b \cdot dr \times 144 \text{ (sq. ins.)};$$

whence the stress per square inch is

$$\frac{\Delta v^2}{144 \cdot g} = \frac{v^2}{10} \text{(approx. for cast iron)}.$$

It is evident that the rim will burst when the velocity is such that this stress becomes equal to the ultimate strength, from which the maximum velocity is

$$v\,(\max) = 12\sqrt{\frac{g\,s}{\Delta}};$$

and the safe velocity is

$$v\,(\text{safe}) = 12\sqrt{\frac{g.f\,\text{safe}}{\Delta}}.$$

It will thus be seen that the safe velocity of a rim is not determined by its diameter or other dimensions, being the same for all sizes and thicknesses of rim if the linear speed is unaltered. One cannot strengthen a rim by putting more metal into it, for thereby the mass is increased and the stress in proportion, the stress per unit of section remaining as before.

The above investigation is applicable only to the case of a rim which is free to assume the circular form at all speeds; and does not, without modification, apply to a rim which is

* See *ante.*

Digitized by Google

constrained at several points by practically rigid arms. The following table gives the values of the stress per square inch for different velocities :—

v =	30	40	50	60	70	80	90	100	110	120 ft. per sec.
f =	90	160	250	360	490	640	810	1000	1210	1440 lbs. per sq. in.

It is difficult to see why so small a stress at comparatively high velocities is so frequently accompanied by rupture of the rim. With disc wheels the constraint is uniformly distributed over the rim, yet these are as liable to burst as the wheels with a limited number of arms. In the latter there is, of course, a stress which is not found in the former, on account of the bulging out of the segments between the arms ; this causing a more or less severe bending action on the rim. It is probable, however, that with curved arms this bulging action is not sufficiently severe to account for the tendency of cast iron to burst at low speeds ; and that the cause must be sought in other actions. The writer is of the opinion that the rupture of wheels is due to rapid but transient stresses of considerable magnitude, superposed on a normal stress which has already brought the metal into a state of greatly reduced strength. When cast iron is under tensile stress, even well within the elastic limit, a very trifling jar or vibration will cause fracture. Precisely this kind of momentary stress is to be found in steam and other reciprocating engines, in which, to the ordinary jars of the machinery, are added the variations in effort on the crank shaft. It is advisable to design the flywheel, when it is to be of cast iron, so that the maximum velocity of the rim shall not exceed from 80 to 100ft. per second. Where the speed of the shaft is so high that it is impracticable to keep the rim velocity within this limit, as in dynamo work, it is usual to employ cast-steel flywheels, or to strengthen the wheel by shrinking on iron hoops.

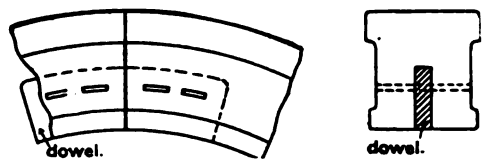

Fig. 16.

When less than 8ft. in diameter, flywheels are usually cast in one piece, but for larger sizes it is found more convenient to build the wheel of a number of segmental castings. If the rim is to be cogged it is not well to cast the teeth on, but to cast them in separate segmental plates, or to mortise them into segmental frames, bolting these on the face of the flywheel. Teeth increase the weight of the wheel without increasing the strength, and consequently necessitate a lower velocity of running. Wheel segments are fastened by several methods, the best of which is known as *dowelling*. A dowelled joint is shown in Fig. 16, which explains itself. The dowel, which is sandwiched into the segments, is of wrought iron or mild steel, and is secured by four through cotters of the same material. Side cover-straps let into the rim are sometimes bolted to the segments ; or a cover-strap is laid on the inside of the wheel at the seam between two segments. A less common and unreliable method consists in shrinking a wrought-iron ring over two lugs, one on each segment, the contracting ring taking a firm grip of each lug and binding the segments together. But the contraction sets up weakening stresses in the ring and renders it unsafe at high speeds. The whole flywheel is keyed to the crank-shaft by means of from two to four steel taper keys sunk into the nave of the wheel and running on flats on the shaft.

The arms of a flywheel are subjected to the following stresses : They have to withstand the dead load of the rim, which causes a tensile stress on the lower and a compressive stress on the upper arms ; they have to resist the tendency of the rim to fly off at a tangent, which sets up severe tensile stresses in all the arms ; and they have to resist the bending actions which arise from the inequality of speeds of the flywheel rim and the shaft, which set up tensile stresses on one half and compressive stresses on the other half of each arm. Formulæ could be deduced for these several stresses, as well as for their aggregate action, but no advantage could be derived from doing so, since no safe rule for the design of the arms would be indicated. In fact, the arms of flywheels are designed from experience, and *not* from theory. It may be mentioned, however, that in small and medium-sized wheels, where the mass of the arms is small compared with that of the rim, the arms should be curved and not radial, in order to eliminate the compressive stress which would otherwise arise on the metal contracting during cooling after casting.

Motor Gearing.

We come now to the consideration of some of the principal forms of gearing which have been used for coupling an electromotor to the machine it has had to drive. As most of these forms of gear have been used for traction purposes, and, indeed, principally so, we shall mainly discuss them in this relation. The various kinds of gearing which have already been considered might, of course, be used for some kinds of motor work ; but it is generally found that a more positive form of force-transmitting appliance, as well as one more compact, is desirable or even essential. In traction work it is absolutely essential that the gearing should be compact, light in weight, durable, simple yet certain in action, free from noise and vibration, and of a reasonable cost. The writer has already, in the introduction, commented on the value of eliminating gearing altogether, but a few remarks may properly be added on the gearless motor. It is hoped that before the readers have arrived at the end of this series of papers they will have seen enough to convince them of the trouble which attends even the best forms of gearing when used on traction motors. Instances will be given of this, and of the defective working of almost every form of motor gear. But the time of gearless motor is hardly yet arrived, and engineers are in most cases compelled to couple their motor to some intermediate mechanism. It is true that the gearless motor is at work, and doing excellent work, on the City and South London Railway ; but the motors there are of exceptionally large power as regards the present development of the branch of engineering, and they are found to be subjected to troubles which could well have been eliminated by the use of gearing. The writer does not advocate the use of gearing on such powerful motor-cars, but is merely pointing out that the absence of it involves the motor armature in dangers which might in certain cases be fatal to success. The experience of the engineers of the South London Railway proves this. Motors without gear cannot well be coupled to the wheels by an elastic cushion or spring, which would take off the shock of the jolts and jars, and are thus liable to have their armatures very severely injured. The frequent burn-outs of the armatures of gearless motors arise largely from this cause. Again, small motors cannot possibly be designed to give the requisite amount of power at low speeds ; so that for tramcars it is still essential to have some form of speed reduction gear and to run the motor at a high rate of revolution.

Steel Spiral Cord Gear.

The first electric tramcar was fitted with this form of gear. This car commenced running in 1881 on the Berlin-Lichterfeld line, and was engineered by Messrs. Siemens and Halske. The motor was coupled to the car axles by means of 27 small steel spiral cords, which ran in V-grooves. Thirteen of these cords drove one of the axles, the remainder driving the other. The centre distance between the driving pulley and each of the axle pulleys was only 2ft. 10½in. ; and the cords were of two strands, $\frac{7}{32}$in. in diameter. This form of gear ran very smoothly and with little loss of power, but it was not found to be positive enough to take the car up a steep gradient ; at starting, a considerable amount of slipping occurred, so that speed was not reached very quickly. The writer does not know of any other traction line on which this gear has been used ; it has been abandoned on the Lichterfeld line, and seems to have only a historic interest. It might, however, well be used in certain cases of stationary motor work, such as in running lathes or sewing machines.

(To be continued.)

HOLDEN, DRAKE, AND GORHAM'S RECORDING INSTRUMENTS.

The ingenious electrical instruments designed by Captain Holden, which have been heard of from time to time, are now being placed upon the market by Messrs. Drake and Gorham. No less than nine kinds of electrical recording instruments are being brought out—there seems, indeed, to be hardly room for so many varieties—but among them several are likely to meet a real want, and to come into general use. The recording ammeter is of peculiar interest, because the action is so powerful, and the friction of the pen need not cause any trouble. Two metal strips shown in Fig. 1, and diagrammatically by A and B, Fig. 2, are secured to upright supports. The upper one only

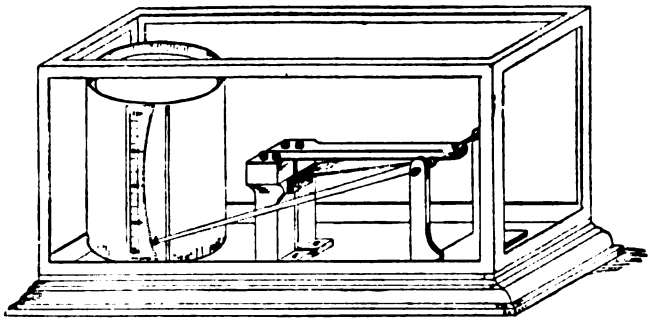

Fig. 1.—Recording Hot-Strip Ammeter.

carries the current, and for this purpose it is slit, the current passing up one side and down the other. The strip B is used only as a tie. The action is shown in Fig. 2.

The two metal strips, A and B, are of the same length. They are fastened together by rivets, at the point E, and also rigidly secured at C and D. If not fastened together at E, they might be supposed to be capable of turning about the points C and D describing the arcs C_1 and D_1, respectively. But, as the strips are rigidly connected at E, if only the upper strip A is caused to extend by a rise of temperature produced in it by the passage of the current, the position which the system of strips will be forced to take up will be one in which the equilibrium is obtained, and this position depends only on the extension of the top strip. For instance, suppose that the amount of extension of the top strip A is equal to the length of the line F G, then the dotted line C G D will represent the position of the system when the strip A has extended by that amount;

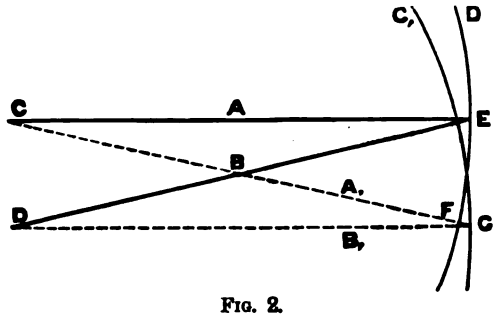

Fig. 2.

it may, therefore, be said that the position is dependent upon a certain current. A rise of temperature in both strips simultaneously, such as would be produced by atmospheric causes, will not affect the system at all, since each strip will lengthen to the same extent independently, and there will be no turning movement.

The record is made on paper attached to a vertical drum revolved by clockwork by means of a pen containing aniline ink, giving a continuous record. The pen is attached by an aluminium arm to an arbor which is turned through a greater or less angle, according to the amount of expansion of the strip. A fixed scale close to the pen enables the amount of current passing at any moment to be read by the eye. This instrument is suitable for either alternating or direct current circuits, and takes little power. As with all such instruments, the scale is not evenly divided. To effect this with an electro-magnetic instrument is almost hopeless, but with a hot strip instrument, the available force is so great that mechanism might be introduced to correct the scale. The advantage of a record with a uniform ampere scale is, that the ampere-hours may be read off direct with a planimeter, giving very useful information in connection with storage batteries. We understand that, though not starting from zero, the scale of the present instrument is fairly uniform.

The feature of the recording voltmeter is its extremely open reading. The electrical portion of the apparatus consists of an open triangular shaped coil shown in Fig. 3 mounted on an arbor working in jewelled mercurial bearings, and moving in a magnetic

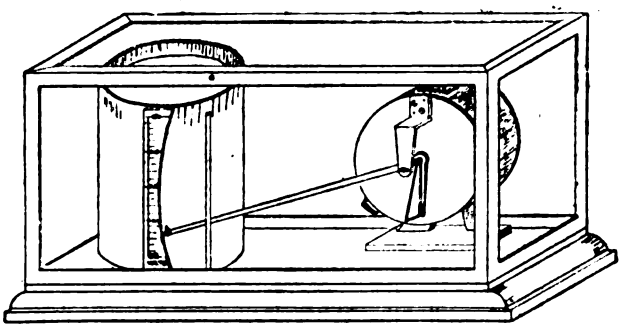

Fig. 3.—Recording Voltmeter.

field. The coil is at first repelled by a radial pole piece, and afterwards attracted by an opposite pole which may be seen in the illustration coming from behind the large coil. The pen is intermittently pressed against the paper by means of an electromagnet in the base of the instrument, worked by means of a main current or by a single separate cell if desired, the contacts controlling this movement are carried by the clockwork in the drum.

It would appear that the Cardew principle was better suited for recording voltmeters than the electromagnetic, for the same reason that we have suggested in the case of the recording ammeter; but Messrs. Drake and Gorham have already tried such an application of the Cardew voltmeter, and it may be presumed that they find the electromagnetic type is more suitable.

Photographic recording instruments, ammeters for direct and for alternating currents, voltmeters and combined voltmeters and ammeters for direct currents are externally all of the same

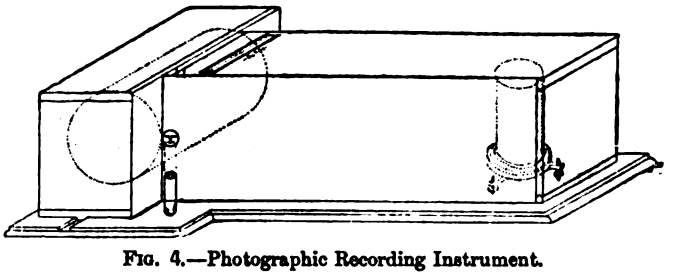

Fig. 4.—Photographic Recording Instrument.

appearance and size, differing only in their internal details. They are about 4ft. long and 18in. wide, and are arranged as shown in Fig. 4.

The revolving clock covered with sensitised paper is contained in a removable box on the left. This box can be removed to the dark room, after closing the shutter, for the paper to be changed and the record developed. The source of light employed may be gas or electric, the beam impinges on the mirror of a Holden D'Arsonval dead beat galvanometer and is therefrom reflected to the surface of the drum; a small portion of the beam is, however, directed upwards and forms a visual pointer on a ground glass scale at the top of the box. The power taken by these instruments does not exceed one watt.

INVESTIGATION OF THE ENERGY CONSUMED BY INCANDESCENT LAMPS.*

BY CH. HAUBTMANN.

Each type of lamp tested was always represented by a batch of ten connected in parallel and grouped in a row. The lamps were tested at the potential marked by the maker, and at a higher potential. Lamps marked 102 volts were generally taken, and 10 were tested at this potential and 10 similar ones at 110 volts. The current was supplied by a battery of E.P.S. cells, and the total number of amperes, as well as the pressu for each row, was recorded by a Richard instrument. Every 50 :60 hours the lamps were taken down and tested one by one, th. exact consumption and the candle-power of each of them being accurately noted. In this way the curves and tables which follow were obtained.

Table I.—*Lamps 16 c.p., 102 volts, made by the Compagnie "La Française." (Vitrite base. Looped filament.)*

102-volt Test.

No. of lamps under test.	Hours.	Candle-power.	Amperes.	Watts per effective candle.
10	0	15·02	0·44	2·98
10	250	10·00	0·43	4·38
9	500	7·01	0·43	6·25

10	250	13·8	0·475	3·87
8	500	11·2	0·475	4·30
7	750	10·3	0·470	5·20
6	1,000	7·0	0·460	6·40

In the 102-volt test of these lamps it was found that the effective candle-power was always below the nominal figure, and that the light fell off very rapidly after the hundredth hour. There was—

1 lamp destroyed after..... 350 hours.
2 ,, ,, ,, ... 750 ,,
5 ,, ,, ,, ...1,300 ,,
1 ,, ,, ,, ...2,150 ,,
1 ,, ,, ,, more than ...3,250 ,,

The average life may be taken at 1,400 hours. The total energy consumed was between 44 and 48 watts, and the mean candle-power was 8 to 8·5 candles (*bougi s décimales*). The curve (Fig. 1) relates to the lamp which lasted 2,150 hours. In all these curves the full line represents current, the dotted line watts per effective candle, as measured on the photometer, and the chain-dotted line candle-power. The abscissæ correspond to periods of 250 hours, and the ordinates to 0·2 ampere, 2 watts, and 5 candles. In the lamps in question the watts per candle become very large after 250 hours.

In tests at 102 volts of a batch of 10 c.p. lamps of the same make (La Française), one lamp gave out after 400 hours, one after 625 hours, and eight lasted about 1,500 hours. The average life of these lamps may be taken at about 1,000 hours. Their candle-power was sensibly 8 candles. and the energy consumed per lamp was about 36 watts. At 110 volts these lamps had from all points of view a higher efficiency. They steadily absorbed 39 watts during their existence, and their average candle-power was 9·25 candles; however, they gave out somewhat more rapidly than at 102 volts.

Table II.—*Lamp 16 c.p., 102 volts. Siemens. (Brass and plaster base).*

0	1,000	0	0	0

* Abstract of an article in *L'Electricien* of September 24, 1892.

The average life of these lamps (Siemens) was about 600 hours, the average candle-power 14 candles, and the energy absorbed 61 watts. At 102 volts the lamps gave out as follows :—

1 lamp after 200 hours. 1 lamp after 950 hours.
2 ,, ,, 350 ,, 1 ,, ,, 1000 ,,
1 ,, ,, 500 ,, 1 ,, ,, 1400 ,,
3 ,, ,, 550 ,,

It may be observed that these lamps differed very little from each other in regard both to consumption and candle-power, which may be attributed to their careful manufacture. At 110 volts they behaved, from the point of view of life, slightly worse than at 102 volts. The curves of one of the 102-volt lamps are given in Fig. 2.

Table III.—*Lamps 16 c.p., 102 volts, "Gabriel." (Brass and vitrite base. Looped filament.)*

102-volt Test.

No. of lamps under test.	Hours.	Candle-power.	Amperes.	Watts per candle.
10	0	18·00	0·63	3·57
10	250	16·54	0·62	3·81

9	750	18·00	0·65	3·00
9	1,000	15·00	0·63	4·62

At 102 volts one lamp was destroyed after 650 hours, two lamps after 1,500 hours, seven lamps lasted more than 2,000 hours. The average life of the "Gabriel" lamps was 1,800 hours, they consumed 63 watts each, with an average candle-power of from 15½ to 16 candles. The curves relating to one of these lamps is given in Fig. 3. The 10 c.p. 102-volt lamps of the same make took 41 watts, lasted 1,500 hours, and gave a mean of 9·5 candles.

At 102 volts the lamps gave out as follows :—

1 lamp after 800 hours. 2 lamp after 1,700 hours.
3 ,, ,, 1,200 ,, 3 ,, at about 2,000 ,,
1 ,, ,, 1,500 ,,

The average life was 1,500 hours, the energy consumed 67 watts, and the candle-power 15. In Fig. 4 the mean curves of these lamps are given.

1 lamp gave out after..... 300 hours.
1 ,, ,, ,, ... 800 ,,
6 ,, ,, ,, ... 1,300 ,,
2 ,, ,, ,, ... 1,500 ,,

These lamps lasted on an average 1,000 hours, they consumed about 60 watts and gave a mean light of 12 candles. They are intended to be replaced after 400 hours' use. The curves of one of these lamps are given in Fig. 8. The 10 p.c. 103-volt lamps of the same makers gave at 102 volts an average light of 8·5 candles, consumed 34·7 watts, and lasted approximately 1,300 hours.

Table IX.—*Lamps 16 c.p., 100 volts. Société Hongroise. (Vitrite base. Looped filament.)*

8	750	16·00	0·66	4·53
7	1,000	15·30	0·66	4·75

One lamp gave out after 600 hours, eight after 1,300 hours, one after 1,600 hours. The life of these lamps is almost 1,250 hours, they consume 62 watts, and have an average candle-power of 16 candles. It is to be remarked that the maximum candle-power is not reached until after 75 to 100 hours, and that these lamps heat considerably. The curves of one of the lamps are given in Fig. 9.

Table X.—*Lamps 16 c.p., 110 volts, made by the Société de Zürich. (Screw base.)*

110-volt Test.

No. of lamps under test.	Hours.	Candle-power.	Amperes.	Watts per candle.
10	0	17·62	0·438	2·73
8	250	16·65	0·416	2·75
6	500	11·00	0·375	3·79
4	750	10·11	0·381	4·19
2	1,000	7·35	0·340	5·15

Average consumption, 45 watts; life, 600 hours; candle-power, 16 candles. Of the lamps which lasted more than 1,000 hours, one had lost 60 per cent. more of its candle-power than the other, which caused the high figure in the fifth column. The curves in Fig. 10 relate to one of these lamps. The 10 c.p. 110-volt lamps of the same firm had an average life of 300 hours, consumed 33 watts, and gave 10 candles.

Some 10 c.p. 110-volt lamps, called "lampes rationnelles Gérard," had an average life of 500 hours, consumed 34 watts, and gave a light of 13 candles.

Table XI.—*General Results of 102-Volt Test for 1,000 Hours.*

Make of lamp.	Candle-power. Nominal.	Maxima at the commencement.	Minima after 1,000 hours.	Average.	Watts per lamp.	Average life.
La Française	16	15·02	5·08	8·50	44·80	1,400

Allg. Elect. Gesell.....	16	15·00	8·80	12·00	50 00	1,000
—	10	10·00	5·08	8·50	34·70	1,200
Société Hongroise	16	21·00	13·25	16·00	62·00	1,250
Société de Zürich	16	17·62	7·35	12·00	45·00	600
—	10	12·92	9 70	10·00	33·00	300
Gérard.....	10	13 80	11·00	13·00	34·00	500

In the latter makes of lamp tested it will be seen from the table that some with a mean illuminating power of 12 to 13 candles (16 nominal) did not take more than 45 watts, and lasted 600 hours. The 10 c.p. Gérard lamps could, if need be, be used in place of 16 c.p. lamps, since they take on the average 50 per cent. less power than old 16 c.p. lamps, the average candle-power of which is not better than that of the 10 c.p. lamps.

THE CONDENSATION OF STEAM.*

It is known that in all steam engines liquefaction takes place in the cylinder, and this is invariably explained on the assumption that the metal being cooler than the steam with which it comes in contact, a transfer of heat takes place from the steam to the iron, condensation ensuing as a natural consequence. No doubt this is the truth, but is it the entire truth? Is this explanation consistent with facts and phenomena taken as a whole? Is the hypothesis competent to explain everything connected with liquefaction in steam cylinders? There is reason to think that the reply must be in the negative; and if so, then we are presented with a very interesting region for physical research; one that can be better explored, moreover, by the physicist than by the engineer, because it is easier to carry out the requisite experiments with the great accuracy required in the laboratory than in the engine room. Our object now is to state the case for inquiry; not to dogmatise, but to suggest.

It was at one time held that cylinder condensation largely depended for its amount on the range of temperature in the cylinder. We have heard it stated, for example, that if the range of temperature in a cylinder were, say, 100deg. and the condensation x lb. per hour, then, all the other conditions remaining unaltered, if the range of temperature were doubled the condensation would become $2x$ lb. per hour; and engineers holding this view very naturally said that the compound and triple-expansion engines were more economical than simple engines, mainly because the range of temperature in each cylinder of the multi-cylinder engine was reduced, as compared with the range in the single cylinder. Reasoning of this kind is seldom or never heard now; because it is well known that cylinder condensation is greater in the triple than any other form of expansion engine, unless it be the quadruple engine. In a word, facts all go to show that cylinder condensation is largely independent of range of temperature. But if this is really, as it is apparently true, then it seems to be clear that we must seek for some other cause of liquefaction. Furthermore, the amount of liquefaction shows itself to be royally independent, bearing no fixed relation to any condition. Thus in two engines practically identical, and working under similar circumstances, we shall find one condensing far more steam than the other.

The whole theory of liquefaction, as commonly stated, is that it can only be brought about by the steam coming into contact with something colder than itself. This assumption is taken for granted; it is held to be capable of convincing proof that so long as steam is kept in a vessel, the walls of which are at its own temperature, no condensation can take place. We are quite willing to grant this, but with a limitation; that is to say, it is quite true of steam kept at rest. The point in doubt is whether it is or is not true of steam in motion. A recent experience—not an experiment—throws some light on this question. Drains fitted to certain steam pipes, all supplied by the same battery of boilers, showed that small steam pipes invariably supplied wetter steam than larger pipes. The steam pipes were all carefully clothed, clothed, indeed, to a quite unusual degree, and the loss by radiation must have been very small; but small or great, there was the water. It is very difficult to believe that in this case—concerning which we may have more to say at another time—the temperature of the metal of the steam pipe could have had much to do with the amount of condensation. Let us consider for a moment what is the nature of the fluid—steam—with which we are dealing. It is of all others perhaps the most unstable that it is possible to produce. A touch with a feather is sufficient to upset the balance in the solid iodide of nitrogen, and an explosion ensues. A touch with a drop of cold water suffices to upset the equilibrium of steam, and the water molecules fall together like a flash. Again, we know that if a permanent gas expands doing work the while, its sensible temperature falls; but when steam expanding does work a portion of it is liquefied. Here there is no question of transfer of heat from a hotter to a colder body. Again, we can go on compressing gas within comparatively enormously wide limits without producing liquefaction; but in the case of steam, if there be water present in sufficient quantity—somewhere about 30 per cent. will suffice—after a certain degree of compression has been reached, no further rise in pressure can be obtained. The steam proceeds to liquefy. The action is as though the water present absorbed it like a sponge. Here, again, we have liquefaction without transfer of heat from a hotter to a colder body. Thus, then, it will be seen that steam will liquefy whether it is doing or has work done upon it; and the action is often apparent in actual indicator diagrams, liquefaction taking place because of the presence of water during the compression period. But this is not all. The presence of some solid body appears to be essential to liquefaction. It has been shown by Mr. John Aitken that if air—that is space, for the air plays a secondary part—saturated with moisture be cooled, the moisture will not deposit unless there are dust particles present on which condensation can take place. During the delivery of a very interesting lecture on liquids and gases delivered by Professor W. Ramsay, on May 8th, 1891, at the Royal Institution, he showed an experiment to illustrate Mr. Aitken's statement of fact. "If," said the lecturer, "air be suddenly expanded it will do work against atmospheric pressure, and will cool itself. This globe contains air, but the air has been filtered carefully through cotton-wool, with the object of excluding dust particles. It is saturated with moisture. On taking a stroke of the pump, so as to exhaust the air in the globe, no change is evident; no condensation has occurred, although the air has been so cooled that the moisture should condense, were it possible. On repeating the operation with the same globe after admitting dusty air—ordinary air from the room—a slight fog is produced, and owing to the light behind, a circular rainbow is seen; a slight shower of rain has taken place. There are comparatively few dust particles, because only a little dusty air has been admitted. On again repeating, the fog is denser; there are more particles on which moisture may condense." This is a highly-suggestive experiment, if regarded in a proper spirit. The difference between vapour suspended in the atmosphere and steam of any pressure is little more than one of degree. If vapour, although cooled, will not condense unless dust particles are present, it is fair to assume, first, that steam would not condense; and, secondly, we may proceed to ask, What effect a difference in the size of the dust particles and in their material would produce on the phenomena?

We believe that in the face of all the facts we have briefly placed before our readers, it is impossible to maintain that steam can only be liquefied by the direct abstraction of heat. We may now proceed a step further, and consider what may happen when steam is in rapid motion round turns and bends. Let us take it for granted, for example, that steam, rushing into a cylinder through crooked ports, comes into contact with metal just of the same temperature as itself, and the conditions are such that this metal can never get hotter than the steam. We have seen that the fluid with which we have to do is in a state of unstable equilibrium. The water molecules are only kept apart by the energy which has been imparted to them by the heat called "latent," but which is really no longer heat. If, now, something occurs to initiate liquefaction, there is no reason why it should not proceed until at least the metallic surface becomes covered with moisture, and the steam is no longer in contact with it. What, it may be asked, can initiate liquefaction under such conditions? The answer can be only tentatively suggestive. The thermo-dynamic theory of gases is supposed to apply to steam. According to it, the molecules are in rapid motion, bombarding the surfaces of the containing envelope, from which they recoil without loss of energy; but this recoil without loss of energy can only hold true of molecules which are perfectly elastic. Let it be granted for argument's sake that the molecules in the steam are imperfectly elastic. So long as the steam is not in motion—and the motion of a current of steam must not be confounded with its intra-molecular motion—the difference in elasticity between steam and a perfect gas is too small to produce an appreciable effect. Let us suppose now that we have an india-rubber ball, which, when dropped on the floor, will always return to the hand so long as it is only thrown down with a certain force, but let the force be augmented sufficiently to injure the ball and it can no longer return. Or to take another case, a steel shot is driven against an armour plate which it is unable to penetrate with a given charge of powder, and it rebounds uninjured from the plate. The charge of powder is increased and the shot breaks up. Now it is evident that the molecules of steam which first rush into a cylinder when the port is opened, are driven clear across to the other side, and violently impelled against the metal; and knowing how fine is the distinction between steam and water, how nice the balance of forces, is it too much to say that the imperfectly elastic molecules will not rebound, but will part with some of their energy to the metal, and falling together will assume the condition of water. All this is pure hypothesis. But it is hypothesis which is consistent with existing theories and existing experiments. Let us, on the other hand, reject the idea that the knocking of steam about, its collision with cylinder walls, the bends in steam pipes, and such like, can have any effect; let us take it for granted that it is impossible, do what we may with steam, to condense it so long as it is in contact with a surface possessing the same sensible temperature. How are we, then, to reconcile this proposition with the facts which we meet with at every turn—the enormous amount of condensation which takes place in the well-jacketed high-pressure cylinder of a triple-expansion engine; the increase in condensation due to the use of small or crooked steam pipes, as compared with those that are larger or straighter; or the circumstance that steam separators, which depend for their operation on the "knocking" of the water out of the steam, often prove failures, taking out a good deal of water, and yet leaving the steam nearly as wet as they received it?

It is, we think, time that the questions we have raised were fairly and dispassionately examined. Either it is or is not true

* From *The Engineer*.

Digitized by Google

that other influences than mere difference of temperature can cause steam to part with its heat. It would not involve the expenditure of very much time, trouble, or money to carry out at least a preliminary trial, which would throw a good deal of light on the points at issue. Thus, for example, a length of 100ft. of straight steam pipe might be fitted up, steam at a given pressure allowed to flow through it, and the amount of condensation measured by collecting, at the end furthest from the boiler, the water deposited. A similar experiment might then be made with a tube of the same length and dimensions, but put together with numerous sharp bends. Different experiments of this kind will suggest themselves. It has long been known to engineers that steam engines with short straight ports are better than engines with crooked and long steam passages. It would be instructive to ascertain to what the economy of the former is due. Is the cylinder condensation less in one case than the other? Finally, we would repeat what we said at the outset, namely, that we do not pretend to dogmatise; all that we have attempted is to show that there is a good case for further inquiry concerning the phenomena of condensation. The subject should be approached with an open mind, and the inquirer should not let himself be persuaded that everything is already known about steam that can be known.

THE FUTURE OHM.*

BY CH. ED. GUILLEAUME.

My readers know that the English propose to abandon the time-honoured British Association unit, and, neglecting the *legal* ohm, to adopt the 106·3 ohm. I propose to-day to inquire into the reason of this reform and to point out its practical bearing.

As early as 1884 several electricians, amongst others Lord Rayleigh and M. Mascart, demanded the adoption of the 106·3 ohm, but the few very low values obtained by well-known physicists caused the mean determination 106 to be adopted, a result which satisfied no one, everyone maintaining the correctness of his own figure. Prof. Rowland, whose determination carried out with great care was yet another argument in support of 106·3, proposed in a circular to reconsider the decisions of the Congress. But people were weary of the discussion and the reform was deemed premature. Moreover, Prof. Rowland's argument seemed absolutely convincing, attributing as he did the coefficient 6 to the high values and coefficients down to as little as 0 to the low values, he could not help finding as his mean the number which he proposed as the result of his calculations.

However, fresh determinations before long proved decisive arguments in the debate. Kohlrausch and Dorn, who had found respectively the values 105·51 and 105·46, passed over to the opposite camp with the numbers 106·30 and 106·24. Wild's determination, when corrected for a fault in his resistance box, rose from 105·68 to 106·18; the lowest numbers as to which there was still some slight uncertainty. Finally, an excellent determination of M. Wuilleumier gave the figure 106·27. This gentleman had employed the formula of MM. Mascart, de Nerville and Benoît for reducing to 0° the mercury unit which he made use of. The determination which I have recently made† of the variation of the resistance of mercury slightly raises this number and brings it up to 106·29. It is unnecessary to discuss these results, suffice it to say that the mean of the determinations worthy of being taken into account is almost exactly 106·3, with individual deviations which do not amount to half unity from the fourth figure. The exact mean seems accurate to within less than two units of the fifth figure. In other words it is very probable that the true ohm is to be found between 106·28 and 106·32, and we cannot reasonably expect to see this more precisely known except after many years. Thus the first point gained is that in adopting the 106·3 ohm we shall no longer work under an uncertainty; the commercial ohm will have what will long remain the most probable value of the true ohm.

It may be objected that the partial adoption of a new ohm will not suppress any of the old ones and will only increase the confusion. An investigation of the facts leads to the opposite conclusion. The *legal* ohm, as I have remarked above, satisfied nobody, and the dissatisfaction was shown by matters being left in *statu quo*. Germany is to-day still using the Siemens unit, England has kept to the B.A. unit, which it is now about to definitely abandon, and France, the most promising country for the reformers, is divided between the *legal* ohm and the B.A. unit. Germany now seems very disposed to adopt the proposals of the British Association, though I am given to understand that this decision was not arrived at without a lively discussion between Prof. von Helmholtz and Dr. von Siemens; nevertheless, the step is taken. The value definitely adopted, acceding as it does to the wishes of French physicists, cannot but be well received in this country, especially as it will put an end to a difference existing between the various State departments. In any case, the Siemens unit and the B. A. unit have had their day, and the new ohm may be considered identical with the true ohm. The only competitor would be the *legal* ohm of 1884, and if this is abandoned, as I hope it will be, the system will be unified. It is, moreover, probable that the resistance boxes have gone ahead of this step, and that coils constructed a few years ago and adjusted to the *legal* ohm have reached, if not passed, the true ohm.

The definition proposed by the British Association may seem uncouth. It would seem, in fact, as if the adoption of an experimental length (106·3) could only be assigned by the *à priori* definition of a cross-section expressed by a whole number, such as the square millimetre. Yet now we have this factor expressed by six significant figures (14·4521 grammes of mercury in the tube). This last definition has only been given for the metrologists. In reality the square millimetre remains the elementary definition, but with the specification that this is arrived at by mercurial weighings, taking unity as the value of the density of water, and 13·5956 as that of mercury. The metrologic definition would have been quite as accurate, and certainly more comprehensible, if, instead of indicating the total mass of mercury contained in a tube 106·3cms. long, the mercury column had been defined as weighing 13·5956 grammes per metre. Let me remark that Barus has shown that the specific resistance of mercury diminishes by 0·00003 of its value when the pressure to which it is submitted is increased by one atmosphere. It would be proper, therefore, to add the following words to the original definition, "under normal atmospheric pressure," which would also be for the use of metrologists only.

With the adoption of an international ohm, one of those differences so prejudicial to progress will cease; prejudicial, because they cause time to be lost in a fastidiously refined work of determination which might be employed on true scientific work. The unification of measures has made such a prodigious stride during the last twenty or thirty years that we may hope in a few years to understand one another's writings without having to make constant use of a conversion table.

INFLUENCE OF THE ELECTRIC LIGHT ON THE STRUCTURES OF TREES, WHEN CONTINUOUSLY AND INTERMITTENTLY APPLIED.*

BY GASTON BONNIER.

Previous attempts at cultivation by aid of the electric light have had more especially for their object the general development of the plants. In my own investigations I have sought to discover what modifications of anatomical structure it was possible to obtain by submitting plants to a light of sensibly constant intensity. Two similar groups of plants were submitted, one to a sensibly constant electric light, the other to the same light from 6 a.m. to 6 p.m., and to darkness between times. A third group placed in open air under normal conditions was used as a means of comparison. The experiments were carried out in the electric lighting station at the Halles Centrales (Paris), where the plants were in a sensibly constant temperature of about 13° to 15° C. (55° F. to 59° F.) and where the air was renewed somewhat slowly. The light was obtained from globe-covered arc lamps and the plants were under glass. The surroundings did not permit of the cultivation of any kind of plant. Austrian and Scotch pines, oak, beech, and birch were experimented on.

The outcome of these experiments goes to show that the electric light continuously applied does not merely retard the formation of the vegetable tissues, but gives rise to considerable modifications of structure in the leaves and shoots of young trees. If a plant respires, assimilates and transpires in an unvarying manner during the whole of the twenty-four hours it seems as if it were troubled by this state of things, and its tissues have in consequence a more simple structure. On the other hand, when the electric light is cut off for twelve hours a day the organic structure more closely approximates the normal.

* Abstract of a Paper read before the Académie des Sciences, September 19th. *Comptes Rendus*, Vol. CXV., No. 12, p. 447.

ELECTRIC LIGHTING PROVISIONAL ORDERS.

In a report dated June 23rd, but only just published, the Permanent Secretary to the Board of Trade states that during the year 1891-92 32 electric lighting orders were applied for. Of these applications 17 originated from Local Authorities and 14 from companies, and 1 from a firm of electrical engineers; 11 related to the metropolis. Last year the total number of applications was 70, of which 37 were made by Local Authorities and 33 by companies, 12 applications relating to London.

As will be seen by the table below, 24 orders in all were granted, and all the Bills confirming these grants subsequently received the Royal Assent. Of the 25 Orders granted, 17 were granted to Local Authorities and 7 to companies.

Digitized by Google

C. = Company. L.A. = Local Authority.

Order.	How dealt with.
	METROPOLIS.
County of London, N. (C.)	Granted in part (County of London Electric Lighting Company).
County of London, S. (C.)	Granted in part (County of London Electric Lighting Company).
East London—Hackney (C.)	The Board of Trade declined to grant the Order, as the promoters (East London Electric Supply Company) failed to satisfy them that they were in a position to discharge the duties and obligations that would be imposed upon them by the Order, if granted.
Hampstead (L.A.)	Granted.
Lambeth (L.A.)	Granted.
North London (C.).	The Order was granted on the understanding that before the introduction of the Confirming Bill the Promoters (Camberwell and Islington Electric Light and Power Supply) should satisfy the Board of Trade that they were in a position to discharge the duties and obligations that would be imposed upon them. They, however, failed to do so, and the Bill was not introduced.
St. Mary (Islington) (C.)	The Promoters (Messrs. Sharp and Kent) failed to produce the consent of the Local Authority or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the Order.
Shoreditch (L.A.)	Granted.
South London (C.)	The Order was granted on the understanding that before the introduction of the Confirming Bill the Promoters (Camberwell and Islington Electric Light and Power Supply) should satisfy the Board of Trade that they were in a position to discharge the duties and obligations that would be imposed upon them. They, however, failed to do so, and the Bill was not introduced.
West London (C.)	The Board of Trade declined to grant the Order, as the promoters (Putney and Hammersmith Electric Light and Power Supply) failed to satisfy them that they were in a position to discharge the duties and obligations that would be imposed upon them by the Order, if granted.
Whitechapel (L.A.)	Granted.
	PROVINCES.
Aberystwith (L.A.)	Granted.
Ashton-under-Lyne (L.A.).	Granted.
Brighton (C.) ...	The Promoters (The Brighton and Hove Electric Light Company) failed to produce the consent of the Local Authority or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the Order.
Dublin (L.A). ..	Granted.
Fareham (C.) ...	Granted.
Govan (L.A.) ...	Granted.
Halifax (L.A.)...	Granted.
Harwich (L.A.)	Granted.
Kilkenny (L.A.)	Granted.
Limerick (L.A.)	Granted.
Liverpool (C.)...	Granted.
Maidstone (L.A.)	Granted.
Newbury (L.A.)	Granted.
Oxford (C.) ...	Granted.
Sheffield (C.) ...	Granted.
Sutton (Surrey) (L.A.)	Granted.
Walton-on-Thames (C.)	The Board of Trade declined to grant the Order, as the Promoters (Weybridge Electric Supply Company) failed to satisfy them that they were in a position to discharge the duties and obligations that would be imposed upon them by the Order, if granted
Waterford (L.A.)	Granted.
Waterford (C.)	Refused. (City of Waterford Electric Supply Company.)
West Ham (L.A.)	Granted.
Woking (C.) ...	Granted.

The following applications for licences have been received since the date of the last report, and are at present under consideration:—The Ogmore Valley Electric Light and Power Supply Company (a portion of the district of the Ogmore and Garw Local Board); the Shropshire Electric Light and Power Company (a portion of the borough of Shrewsbury); the Isle of Wight Electric Lighting Company (the Urban Sanitary District of West Cowes).

Appended to the report is a list of the Provisional Orders confirmed by Parliament (prior to the 1891-92 Session) and of the licences granted by the Board of Trade, since the passing of the Electric Lighting Act, 1882, showing those which have since been revoked or repealed. From this list it appears that, including the Provisional Orders contained in the above table, no less than 116 Local Authorities and 60 Companies possess electric lighting powers.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 17, 1892.

The Western Union Company.—The Western Union Telegraph Company has decided to increase its capital stock to $100,000,000. The present capitalisation of the Company being $86,200,000, this proposed increase of $13,800,000, it is said, represents money expended for extensions and improvements.

Electrically Propelled Vehicles in Chicago.—Considerable interest is manifested in Chicago in the subject of electrically propelled vehicles in view of the fact that the possible field of usefulness of such vehicles at the time of the World's Fair may be large. An electric carriage, under the control of Mr. J. B. McDonald, president of the American Battery Company of Chicago, was operated last week on the streets of that city, and from the reports made the working of the vehicle seems to have been a success. The total number of cells carried on the vehicle is 24. Each of these cells is of 150 ampere hours' capacity, with a total available E.M.F. of 48 volts. The cells are arranged in sets of eight each, one set being placed under each of the three seats of the carriage. The motor used is rated at 2½ H.P., is series wound, and is connected to the rear axle of the carriage through a train of ordinary gearing. The rear carriage wheel is four feet in diameter, and may be driven at a speed corresponding to six or seven miles per hour. The controlling apparatus, which consists of a contact bar and a reversing switch, is attached to the under side of the carriage floor. The steering apparatus is of peculiar construction; each of the two front wheels bears upon a swivelled bearing, so as to swing horizontally and independently of the axle, which is rigidly fixed in a position parallel to the rear axle. A yoke bar connects the two front wheels, and to this bar is connected the gear wheel upon the steering lever, which permits of the two wheels being swung to the right or left as desired. Some recent tests with this carriage, made by Mr. Pumpelly, show that the average current called for when carrying a load of six people varies from 25 to 35 amperes under ordinary running, and rises as high as 50 amperes when starting from a full stop.

The Proposed Chicago-St. Louis Electric Railway.—Work was commenced last week on a section of the proposed Chicago and St. Louis Electric Railway, and the construction will be pushed forward as rapidly as possible. A good deal of doubt has been expressed as to the genuineness of the intentions of the Company promoting this scheme, but, notwithstanding a good deal of opposition from the technical press, the scheme seems to be well founded and to have excellent backing. Dr. Wellington Adams, it is announced, will make a trip to Europe in a week or two in connection with the car equipment, which will probably be manufactured abroad where considerable experience has already been had with multiphase motors.

CORRESPONDENCE.

NAVAL SIGNALLING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have noticed a letter from Mr. Kelway in your issue of the 23rd inst. in which, if he will pardon me saying so, I think he has totally mistaken the signalling requirements of the Navy. It is of very little importance to the Navy at large that signals may be read by every casual observer; in fact, in many cases such a thing may be highly objectionable. It is impossible except at great length to lay down exactly what system we require, since signalling at night may take either the form of a lengthy communication or of an executive signal which may require instant recognition and immediate action. The most untechnical person can easily see the vast difference between the *desiderata* of the two.

In the Navy the system we try to get is "the best to suit our requirements," and although I am perfectly aware of the

Digitized by Google

great disadvantages of our system of flashing lights, still I am equally aware of the enormous disadvantages that many other systems possess, and the numerous difficulties that beset the whole question of which persons unacquainted with our requirements are totally ignorant. Mr. Kelway may rest assured that if he has presented his system of signalling to the Admiralty it will receive their full consideration, and if there is in their opinion the slightest chance of its ultimate success it will be handed over for trial to men of considerable experience and thoroughly qualified to judge of its capability. One word more. I know there is a prevalent opinion that we naval officers are behind the times, and ultra-conservative as regards improvements, but such judgments I venture to think are hastily arrived at. We possess considerable practical knowledge of life and the conditions that surround life at sea, experience that rarely falls to shoregoing people, and at the same time we have to arrange all our appliances for war time as well as for peace, and if to this we add the fact that adoption of instruments, machines or systems of communication affect several hundred ships, I think we may well be excused if we act with deliberation, and are not carried away like the Athenian of old "by every new thing."—Yours, &c.,

R. H. Bacon, Lieut. R.N.

H. M. S. "Vernon."

EARTH CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: With reference to your article on Earth Currents in issue of August 5th, the following may be of interest:—On July 12th from 5:30 to 7:30 p.m. (Greenwich time) we had very strong E.C.'s on north and south of here, and again on 16th from 10:30 a.m. to 9 p.m. (Greenwich time) E.C.'s were excessively strong, and caused great difficulty in working at times. The same trouble was experienced south.—Yours, &c.,

William H. Mardock.

The Western and Brazilian Telegraph Company,
Ceara Station, August 29, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Tenders Invited.—The Dundee Gas Commissioners invite tenders for the supply and erection of two overhead travelling cranes for the electric lighting station. Particulars can be had from Mr. T. Thornton, clerk to the Commissioners, to whom tenders must be delivered on or before October 10th. Further particulars are given in our advertisement columns.

——— The Glasgow Police Commissioners invite offers to renew and maintain the Street Fire Alarm and Telegraph Lines belonging to the Fire Department. Tenders must be in by 10 a m. on 7th prox.

——— The Derby Corporation are prepared to receive tenders for the builders' work in the engine and boiler house, &c., and accessories, at the Central Station. Tenders must be in by 12 on 10th prox.

——— The Town Council of Windsor invite tenders for the supply of gas or other illuminant for the public lamps, for one year. Tenders to be in by the 8th prox.

Tenders Accepted.—Mr. T. Barton, of Blackburn, has received the contract for supplying and fixing electric light fittings for the new police-courts at Nelson.

Appointment Vacant.—The Electric Light Committee of the Dublin Town Council require a clerk and storekeeper not more than 30 years old, at a salary of 30s. per week. A knowledge of electricity is desirable. Particulars of Mr. Beveridge, town clerk, Dublin, to whom applications must be sent by 5 p.m. on October 3rd.

Edison General Electric Company.—We understand that this Company is about to be reorganised, and that it is intended to close the London office.

Bankruptcy.—*In re James Collins.*—An inquiry into the circumstances attending the failure of this bankrupt took place at Brighton last week, the result being that the debtor passed his examination.

In Liquidation.—The New British Iron Company, one of the leading Staffordshire marked bar iron houses, has gone into voluntary liquidation. The Company is a very old-established one, and is the owner of the well-known Corngreaves Ironworks.

General Electric Power and Traction Company (Limited).—Messrs. Harpers (Limited), of Aberdeen, have placed an order for the electric lighting of their very extensive new workshops with the above firm.

Personal.—Mr. Albion T. Snell is practising as a consulting engineer, making a specialty of electrical transmission of power, more particularly with reference to colliery and mining work, and is working in conjunction with Messrs. Walker and Hardwick, of Sheffield and London. Mr. Snell's offices are at Suffolk House, Laurence Pountney-hill, E.C., and North Church-street, Sheffield.

Messrs. Mavor and Coulson.—This firm have completed the installation of the electric light at Ardrossan Harbour.

Messrs. Evered and Co. (Limited).—This firm will shortly issue their new catalogue, which will contain a number of new designs in electric light and combination fittings. A large assortment of pillar lamps has been added to the former lists, many of these being marked at prices much below previous quotations. A feature of the list is the new six-light billiard-table group (E482) marked at £9. 9s., and several examples of dining-room suspender lamps, which are made to take any kind of silk shade. Numbers E852 and E853 in the list are particularly good examples of these dining-room lamps, which are stocked in triple lights, and are made to order for any number of lamps. Novelties are also shown in vestibule lights, and some choice specimens of wrought-iron work will be found included. Illustrations E974 and E975 show a new method of sliding arrangement for pedestal lights, by which the flexible wire is fed through the centre of the pedestal, instead of entering at the top or being attached from the outside. Messrs. Evered and Co. have a patent switch, which they make in all sizes, an advantage claimed being their high insulation. The new catalogue also contains illustrated particulars of a variety of electrical accessories manufactured by the firm.

Messrs. Drake and Gorham.—Amongst the contracts recently obtained by this firm for lighting are those for the offices of Messrs. John Dickinson and Co., Old Bailey; the Alliance Assurance Corporation, St. James's-street; Lord Knutsford's London residence in Eaton-square; Mr. James Lowther's residence in Wilton-crescent. Plants are being put down for the Manchester and Liverpool District Banking Company at Manchester, for Mr. C. Swinfen Eady at Weybridge, and a turbine installation at Ewell Court, in addition to extensions to the Inner Temple installation.

Messrs. L. M. Ericsson and Co.—This firm, whose works and offices are situate at Stockholm, Sweden, have just issued the third edition of their illustrated catalogue of telephonic, telegraphic and general electrical apparatus. The book is well arranged and neatly printed in English and German parallel columns throughout. Some admirable illustrations of the various manufactures of the firm are given, the whole occupying 80 quarto pages.

Electric Launches.—Mr. K. Brown, of the Ray Mead Works, Maidenhead, has recently built an electric launch suitable for the Norfolk Broads. This is one of a flotilla of similar boats to be ultimately supplied. The launch batteries are at present charged at the works of Messrs. Laurence, Scott and Co., Limited, but it is anticipated that charging stations will shortly be erected at Oulton, Wroxham, and Yarmouth, in addition to Norwich.

Telephone Extension.—The *Financial News* states that a new Telephone Company is about to be started in Mexico, promoted and managed by Messrs. Ernest and Enrique Ascorve, with a capital of $160,000, in $100 shares.

Exhibition.—It is stated that the electrical section of the exhibition shortly to be held in Rome will be international in character.

Belfast.—At the last meeting of the Lighting Committee of the Corporation it was, we understand, decided to recommend the introduction of the electric light, the idea being to make a commencement with 10,000 lights. This recommendation will doubtless be approved at the meeting on Saturday next. As showing the interest the subject is arousing, a representative of a leading Belfast paper is at present in London collecting material to enable that journal to put before its readers the many advantages of the electric light, the question having recently come prominently forward in connection with the difficulty of extending the present gas-works.——It is reported that the installation of the electric light at the Cogry Mills, Belfast, has been so successful that it is probable the light will be introduced on a large scale into neighbouring establishments.

Bowness.—At a meeting held last week, the Bowness Local Board had under consideration the question of the electric light installation, the result being that the Board was in favour of a Company undertaking the lighting of the town, on condition that

Digitized by Google

the contract was entered into with the Local Authority on terms favourable to the ratepayers. Messrs. R. H. Fell and Son will most probably be granted permission to lay electric cables along the main roads of the district.

CHATHAM.—A scheme for the purchase by the Town Council of the property of the Water and Electric Light Companies came before the last meeting of the Council, but was adjourned to the next meeting, not, however, before some notes which had been prepared by the Mayor had been distributed. It is understood that the proposal is viewed with favour by many members of the Council.

DEWSBURY.—It is stated that a poll of the inhabitants of Dewsbury will shortly be taken to settle the question whether the township is to be lighted by electricity or gas.

MIDDLESBOROUGH.—It has been decided to form a sub-committee to prepare a report on the question of electric lighting for the town.

SYDNEY, NEW SOUTH WALES.—In reference to the electric lighting of Sydney, a Paper was recently read before the Royal Society, Sydney, by Prof. Selman, suggesting that the high-tension direct current transformer system should be used in lieu of the scheme which has been previously under consideration.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

September 3, 1892.

15,833. W. P. THOMPSON. Liverpool. Improvements in telegraphic apparatus. (L. Dill, Germany.)

15,840. R. E. B. COMPTON and E. A. N. POCHIN. London. Improvements in electric arc lamps.

15,865. C. W. ATKINSON. London. Improvements in electrical switches.

September 5, 1892.

15,876. J. MUIRHEAD. Glasgow. Improvements in and relating to telephonic instruments.

15,887. H. H. FREI. London. Improvements in, and apparatus for, obtaining metals by electrolysis.

September 6, 1892.

15,958. C. J. J. COX. London. Cox's "Multum in Parvo" electric top band for boots.

15,959. E. S. and E. S. D'ODIARDI. London. Improvements in pneumo-dynamo meters.

15,960. E. S. and E. S. D'ODIARDI. London. Improvements in means of conveying or administering electricity for medical purposes or others.

15,961. E. S. and E. S. D'ODIARDI. London. Improvements in charging vapours for inhaling purposes or others with electricity.

15,962. E. S. and E. S. D'ODIARDI. London. Improved means for administering electricity to animals or human beings.

15,963. E. S. and E. S. D'ODIARDI. London. Improved means for administering or conveying electricity for medical or other purposes.

15,969. G. J. SPEED. London. Improved electric cork-ribbed belt.

15,972. SIEMENS BROS. AND CO. (LIMITED). London. Improved arrangements of pulleys and bands for driving machines from electromotors. (Messrs. Siemens and Halske, Germany.)

15,991. P. H. HOLMES. London. The manufacture and production of compositions of matter suitable for use for bearings, packings, projectile guides or rings, electrical conductors and analogous articles.

15,992. P. H. HOLMES. London. Improvements in the manufacture of composition bearings, packings, projectile guides, or rings, or analogous articles, applicable also for use as electric conductors.

15,994. P. H. HOLMES. London. Improvements in electrical conductors.

15,998. A. V. NEWTON. London. Improvements in the manufacture of electric circuits and cables. (J. A. Barrett, United States.)

15,999. A. V. NEWTON. London. Improvements in the manufacture of electrical circuits, cables and other articles alike subject to flexure. (J. A. Barrett, United States.)

September 7, 1892.

16,014. J. W. MACKINTOSH. London. Improvements in phonographs.

16,046. H. Y. CASTNER. London. An improved process of an apparatus for the electrolytic decomposition of alkaline salts.

16,055. T. R. FREEMAN and W. W. POPE. London. Improvements in dynamo-electric machinery.

September 8, 1892.

16,114. E. CURTICE. London. Improvements in signalling, announcing and advertising by electric light on the clouds or other vapour and in apparatus therefor.

15,124. A. R. BENNETT. London. Improvements relating to telephonic switching apparatus.

16,126. W. MOSELEY. London. Improvements in soldering joints of electric wires.

September 9, 1892.

16,138. H. A. C. SAUNDERS. London. Improved means for transmitting telegraphic signals through submarine and like cables.

16,142. J. F. HOFFGAARD. Manchester. Improvements in telegraphic receiving instruments. (H. P. Fryd, Denmark.)

16,143. S. HUGHES. Birmingham. Improvements in telegraphic receiving instruments.

16,154. J. F. MILLS. London. A new or improved lubricating inking apparatus for telegraphic purposes.

16,176. E. H. P. HUMPHREYS and W. FRIESE-GREENE. London. Improvements in the means or apparatus for measuring electricity.

September 10, 1892.

16,201. J. B. FACHRIS. London. Improvements in galvanic batteries.

16,254. S. T. WYAND and L. SCHRAMM. London. An improvement relating to electrical switches, sockets, cut-outs, and like electrical appliances.

16,262. C. A. FAURE. London. Improvements in the electrolytical decomposition of alkaline chlorides for the production of chlorine and alkalies and in apparatus therefor.

September 12, 1892.

16,284. W. JENNINGS. Hertfordshire. Improvements in electric call-bell indicators.

16,300. H. H. FREI. London. Improved method of and means for supplying electricity to the carbon electrodes employed in the electrolysis of fused electrolytes.

16,301. H. T. WILSON and N. SCHWAB. Birmingham. Improvements in electrical fire and burglar alarm connections.

16,315. F. E. W. BOWEN. London. Improvements relating to electric telegraphs.

16,328. E. SPRATT. London. A new principle of conveying to or from the earth electricity to human beings.

September 13, 1892.

16,335. E. M. HARRISON. London. Improvements in electric telephones.

16,371. W. H. SOLEY, W. W. PEBKINS, J. WOLSTENCROFT, W. O'NEIL and W. H. YELLAND. London. Improvements in electric lo omotives

September 14, 1892.

16,427. G. A. NUSSBAUM. London. Improvements in magneto generators, battery switch bells, and the like.

16,434. C. M. DORNAN and R. A. SMITH. Manchester. Improvements in the construction of electric light switches, cut-outs, ceiling plates, wall connectors, lampholders, and the like.

16,456. E. F. MOY and F. TEAGUE. London. Improvements in or relating to ammeters or voltmeters.

16,461. W. MAIN. London. Improvements in secondary batteries. [Date applied for under Patents Act 1883, Sec. 103, February 15, 1892, being date of application in United States.]

16,469. C. E. WEBBER. London. Improved contact fittings for movable electric lamps.

September 15, 1892.

16,489. A. L. TAYLOR. Liverpool. An arrangement for working an electrical rock drill or similar apparatus.

September 16, 1892.

16,545. A. E. J. BALL. Plymouth. Improvements in and relating to dry and other galvanic batteries.

16,550. J. F. HOFFGAARD. Manchester. Improvements in electric telegraphs. (H. P. Fryd, Denmark).

16,561. A. W. MESTON. London. Improvements in dynamo-electric machines and motors.

16,570. F. E. ELMORE. London. An improved method and apparatus for electrical propulsion of vehicles.

16,571. WOODHOUSE AND RAWSON UNITED, LIMITED, and W. S. RAWSON. London. Improvements in the connections of electric motors with the sources of electricity from which they are supplied.

16,588. P. GARUTI. London. Production of oxygen and hydrogen by electrolysis of water. [Date applied for under Patents Act 1883, Sec. 103, April 25th being date of application in Italy.]

September 17, 1892.

16,613. J. H. GREENWOOD. London. Improvements in fire alarm telegraphs.

COMPANIES' MEETINGS & REPORTS.

Brush Electrical Engineering Company (Limited).

The following is the third annual report of the Directors of this Company, to be presented to the shareholders at the general meeting to be held at Cannon-street Hotel, London, E.C., this day (Friday), the 30th inst., at 3 p.m.:—

The profit and loss account to 30th June last shows a gross profit of £55.757. 11s. 3d., inclusive of the amount brought forward from last account. After deducting standing charges, maintenance of buildings, plant and patents, and interest on debentures and New Debenture Stock, there remains a balance of £27,660. 15s. 8d. The Directors recommend that, as in former years, £3,000 be applied to reduction of property, patents, and goodwill accounts, and £800 to reduction of preliminary and other expenses account. An interim dividend at the rate of 6 per cent. per annum, upon both Preference and Ordinary shares, absorbing £11,553. 16s. 1d. has been paid for the six months ended December 31, 1891, and the Directors recommend that £11,553. 16s. 1d. be applied to the payment of a further dividend, making 6 per cent. per annum upon both classes of shares, the balance of £753. 3s. 6d. being carried forward to next account.

With a view to providing additional capital for extensions at the Loughborough Works, and to enable the Company to deal adequately with contracts on hand for electric lighting and other work in the City of London and elsewhere, the capital account has during the past year been increased by the issue of shares to the amount of £11,223. During the year the £75,000 Six per Cent. Mortgage Debentures of the Company have been redeemed by the issue of £125,000 Four and a-Half per Cent. Perpetual Debenture Stock, of which the major portion was issued to holders of the £75,000 Mortgage Debentures at the rate of £110 Four and a-Half per Cent. Debenture Stock for each £100 Six per Cent. Mortgage Debenture. The amount of this premium has been added to the property, patents, and goodwill account.

The capacity of the Company's works at Loughborough has been increased during the past year by the erection of additional buildings and plant, and the Company is now in a favourable position for undertaking large central station and other contracts. Further additions, with a view to the concentration of the Company's manufacturing operations at Loughborough, are now in progress. The locomotive and rolling stock department continues satisfactory, and important contracts have been carried out during the year. The vertical steam engines manufactured by the Company specially for driving electrical machinery also continue to grow in favour, and numbers have been supplied to other firms engaged in the electrical industry.

Satisfactory advance has been made with the City of London electric lighting contract referred to in the last report, and the plant already installed is now regularly supplying public and private electric lighting in a large part of the City of London. The plant, so far erected for the City of London Electric Lighting Company, represents only a small portion of the total work to be done for that Company, and, in view of the numerous applications which have been received for light in the City of London, it may fairly be anticipated that the work to be executed during the current year under this contract will add very materially to the volume of business. The Company has also during the past year secured large contracts from municipalities for the equipment of electricity supply stations in several of the leading towns of Great Britain; and the prospects of other local authorities deciding to carry out central station works, and of this Company sharing fully in the execution of such orders, are encouraging.

The Directors deemed it advisable to make a comprehensive exhibit of the Company's manufactures at the recent Crystal Palace Electrical Exhibition, and there is every indication that the results will justify the course adopted. The whole of the cost connected therewith has been written off in the profit and loss account before arriving at the net balance shown.

The Directors submit, as before, a separate balance-sheet of the Company's foreign and colonial branches at Vienna, Temesvar, and Australia. The Austrian and Hungarian businesses of the Company have made good progress during the past year. Negotiations in connection with a re-arrangement of the Company's interests in both businesses are still in progress. The policy of establishing a branch of the Company in the Australasian Colonies is now bearing fruit. Some important contracts and sales have been effected, and others are under negotiation. The Company own the Edison patents throughout Australasia; and recent decisions in

Digitized by Google

the New South Wales Courts have confirmed these patents as controlling the sole right to the manufacture and supply of incandescence lamps.

Mr. E. Garcke has resigned the position of Managing Director, but retains his seat at the Board. Messrs. John S. Raworth and R. Percy Sellon, who formerly held the positions of Chief Engineer and Assistant-Manager respectively, have been appointed Joint Managers. Mossrs. E. Woods and E. Garcke retire by rotation, and offer themselves for re-election, and Messrs. Cooper Brothers and Co., the auditors, offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

BATES STEEL COMPANY (LIMITED).—Capital £350,000, in £10 shares. To acquire, develop, and turn to account certain patents and patent rights granted to F. G. Bates for an improved process for use in converting iron or low-grade steel into high-grade steel.

CHARLES JORDAN AND SONS (LIMITED),—This Company has been registered with a capital of £30,000, in £10 shares, to carry on at Newport (Mon.) and elsewhere the business of steel, iron, and brass founders, mechanical and manufacturing engineers, ship repairers, &c.

DI-BASIC IRON AND STEEL (PIONEER) COMPANY (LIMITED).—This Company was registered on September 24, 1892, with a capital of £200,000, in £2 shares, to acquire, develop, and turn to account the inventions of Messrs. John Heaton and G. H. Holden, of 41, Corporation-street, Manchester, relating to the manufacture of iron and steel, and to carry on the business of metal workers, boiler-makers, electricians, mechanical and electrical engineers, manufacturing chemists, &c.

GLOBE ENGINEERING COMPANY (LIMITED).—This Company has been registered, with a capital of £40,000, in £5 shares, to carry into effect an agreement between A. G. Brown and this Company, for the acquisition of the undertaking of ironfounders, iron and steel manufacturers, engineers (mechanical and electrical), tool makers, &c., to acquire patents and inventions of every description, and to develop and turn to account the same.

MISCELLANEOUS.—BROOKES AND CO. (LIMITED), iron and steel workers, wire drawers, &c.; capital, £5,000, in £1 shares.——EXCELSIOR STEEL AND IRON COMPANY (LIMITED), iron and steel manufacturers, mechanical and electrical engineers, &c.; capital, £5,000, in £10 shares.——REFEREE CYCLE COMPANY (LIMITED), cycle manufacturers, electricians, electrical engineers, &c.; capital, £25,000, in £1 shares.

CHINA AND JAPAN TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to June 7, 1892, was filed on the 13th. The Company was registered on January 31, 1883, with a capital of £200,000 in £1 shares. At the time of making up 14,761 shares had been taken up, and all had been issued as fully paid.

COLUMN PRINTING TELEGRAPH SYNDICATE (LIMITED).—The annual return of this Company, made up to February 15, 1892, was filed on August 20th. The Company was registered on August 3, 1889, with a capital of £10,000 in £50 shares; and in May, 1890, the capital was raised to £25,000 by the creation of 300 new shares of £50 each. At the time of making up 209 shares had been taken up, of which 100 had been issued as fully paid. Upon the remaining 109 shares £31. 5s. per share had been called, resulting in the payment of £3,177, and leaving £212. 10s. in arrears (*i.e.*, according to the return, which figures are, however, incorrect).

CORIFACT SYNDICATE (LIMITED).—An agreement was filed on September 5th between William A. Burrows and John W. Savage of the one part, and the above-named Company of the other part, providing for the sale to the Company of certain letters patent, inventions, and secrets for the industrial utilisation of heather waste for the sum of £11,100, to be satisfied by the allotment of 11,100 fully-paid shares in that Company. The Company was registered on April 23, 1892, with a capital of £15,000 in £1 shares, to carry on the business of artificial leather and leather board manufacturers, electrical apparatus manufacturers, insulated wire manufacturers, &c.

EASTON AND ANDERSON (LIMITED).—The annual return of this Company, made up to May 13, 1892, was filed on May 21st. The Company was registered on June 4, 1888, with a capital of £250,000 in £100 shares, being afterwards divided into 2,060 ordinary and 440 Five per Cent. Preference Shares of £100 each. At the time of making up all the ordinary and 184 preference shares had been taken up, the ordinary shares having been issued as fully paid. The full amounts have been called and paid on the preference shares.

EXCHANGE TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to August 12th, was filed on the 19th. The Company was registered on March 28, 1872, with a capital of £200,000, in £10 shares, to erect, maintain, and work telegraphs and transmit telegrams in accordance with a licence granted by the Postmaster-General. At the time of making up the capital consisted of £246,250, divided into 8,125 "A" and 16,500 "B" shares of £10 each, all of which have been taken up, and 2,125 "A" shares have £8 considered as paid on each, and 16,200 "B" shares have been issued as fully paid upon the remaining 6,000 "A" shares, the full amount had been called resulting in the payment of £53,898, leaving £102 in arrears.

EXETER ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to August 20th, was filed on the 23rd. The Company was registered on March 9, 1888, with a capital of £20,000, divided into 1,990 ordinary and 10 founders' shares of £10 each. At the time of making up, 1,008 shares had been taken up, the full amounts called resulting in the payment of £9,880, leaving £200 as yet unpaid.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY.—The Directors of this Company have declared an interim dividend for the quarter ended September 30th of 12s. 6d. per cent. on the ordinary stock, and 25s. per cent. on the preferred stock, less income-tax, payable on November 1st to the stockholders registered on the books of the Company on September 30th.

BLACKPOOL ELECTRIC TRAMWAY COMPANY (LIMITED).—An extraordinary general meeting of this Company was held at Blackpool on Saturday for the purpose of winding up the Company, the Directors having accepted an offer of £15,750 from the Corporation for the whole of the plant, stock, &c. Mr. J. Horsfall presided, and proposed that the Company should be voluntarily wound up. Mr. Thomas Bottomley, of Marsden, near Huddersfield, seconded the motion, and after a short discussion the resolution was passed unanimously. Upon a vote of thanks to the Chairman being proposed, Mr. J. Wheway said that the Blackpool Corporation had not treated the Company with the consideration they merited. The tramway had been one of the principal means of bringing people into the town, but the bargain which the Corporation had struck in purchasing the trams reflected dishonourably upon them. After some confusion the vote of thanks was carried, and the proceedings concluded.

BRITISH GUIANA ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).—The half-yearly meeting of this Company was held on August 25th, Mr. A. Weber in the chair. The six months' working had resulted in a deficit of $4,947·60, but the causes were held by the Chairman to be of an exceptional character, and not likely to recur. The revenue from private lighting was rapidly increasing, the receipts for the six months ended June 30, 1892, being $3,609, as compared with $1,172 in the corresponding period of 1891.

CALLS DUE.—*Oct. 1.*—COLLIER TELEPHONE AND ELECTRICAL MANUFACTURING COMPANY, £2. 10s. on 5,000 ordinary £10 shares; ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY, 15s. (final) on 20,500 perpetual Ten per Cent. Preference £2 shares. *Oct. 3:* NEW TELEPHONE COMPANY, £2 on 48,800 ordinary £10 shares. *Oct. 31:* ISLINGTON AND GENERAL ELECTRIC SUPPLY, £1 on 45,000 £5 shares.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended Sept. 25th were £768, as against £708 for the corresponding period of last year, being an increase of £60. The total receipts for half-year amount to £9,971, against £9,126 in the corresponding period of 1891, being an increase of £845.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The list of subscriptions opened on Wednesday last, and closes this day (Friday) at 4 p.m. for both town and country, of an issue of 20,000 Six per Cent. Preference Shares of £10 each in the above Company. The shares are issued at par, and are payable £1 on application, £1 on allotment, £2 on November 15th, £2 on January 16th, £2 on March 15th, and £2 on May 15th next. Applications from holders of the ordinary shares will have preference. The issue is for one-half of the £400,000 which the Directors have power to issue, and it is intended to issue the remaining 20,000 shares towards the middle of 1893 at a premium. The prospectus states that at the present time current is being supplied to public street lamps and to about 16,000 incandescent lamps of private consumers, and that it is estimated that the additional capital now issued will enable the Company to supply current to about 150,000 private lights. The Company has laid more than 320 miles of mains, and 90 miles of cable have been already drawn in. The Directors estimate that the net revenue derivable from the private lamps, for which applications have already been received, will more than cover the full interest on the present issue, for which it is intended to apply for a Stock Exchange quotation. Prospectuses, &c., can be obtained from the bankers and brokers, the former being the London and Westminster Bank, Lothbury, E.C.; and Messrs. Sir Samuel Scott (Bart.) and Co., of Lothbury, E.C., and 1, Cavendish-square, W., and the latter, Messrs. Foster and Braithwaite, 25, Austinfriars, E C. The offices of the Company are situate at 1 and 2, Great Winchester-street, E.C., the secretary being Mr. J. Cecil Bull.——Application has been made to the Stock Exchange Committee to allow the further issue of 9,848 of the Company's ordinary shares, Nos. 70,153 to 80,000, to be quoted in the Official List.

COMMERCIAL CABLE COMPANY.—The Commercial Cable Company's office at 4, Charing-cross, has been removed to 1, Northumberland-avenue (opposite the Grand Hotel), W.C.

DIVIDENDS PAYABLE.—*Oct. 1:* COMMERCIAL CABLE; DIRECT SPANISH TELEGRAPH; HENLEY'S TELEGRAPH WORKS. *Oct. 14:* EASTERN TELEGRAPH. *Oct. 15:* EASTERN EXTENSION TELEGRAPH. *Oct. 18:* GLOBE TELEGRAPH AND TRUST.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—Mr. J. Spencer Balfour, M.P., has resigned his position as a Director of the above Company.

EVERED AND CO. (LIMITED).—The Directors of this Company have declared an interim dividend at the rate of 7½ per cent. per annum for the half-year ended June 30th last.

WATERLOW AND SONS (LIMITED).—A dividend of 3 per cent. on the preference shares, making 6 per cent. for the year, and an interim of 4 per cent. on the ordinary shares, has been declared, both payable this day (Friday).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Sept. 23, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,009.

WESTERN UNION TELEGRAPH COMPANY.—The Directors have declared the regular quarterly dividend of 1¼ per cent. It has been decided to recommend to the next annual meeting of stockholders, to be held next month, that the capital stock of the Company be increased from $86,000,000, as it now is, to $100,000,000.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 751.—Vol. XXIX. FRIDAY, OCTOBER 7, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The means for producing considerable quantities of liquid oxygen which have been provided at the Royal Institution, yielded during the earliest experiments most interesting results of a qualitative character, notably the discovery of the increase of the magnetic susceptibility of oxygen. As we informed our readers a fortnight ago, the low temperatures which Prof. Dewar can command have been employed by him, in collaboration with Dr. Fleming, to extend our knowledge of the electrical resistance of metals. A short Paper on this subject appears in the current number of the *Philosophical Magazine*, and is reproduced elsewhere in our present issue. It may be confidently expected that, since a large number of careful measurements have been made, some further account of them will be published, and the authors, indeed, refer to charts illustrative of their results, though no such diagrams accompany their present communication.

As the graphic representation of such observations as those which Profs. Dewar and Fleming have made are very much more easily appreciated than tables of figures, we have plotted the results and have appended the diagrams to their communication. In these diagrams we have not attempted to run regular curves through the observed points, but have merely joined them together by straight lines to prevent confusion. In order to save space, the scales are different in each case, but we have given absolute zero and zero specific resistance in all of them. The convergence of the resistances of the pure metals towards absolute zero is very clear, though a greater curvature might have been expected; in the case of nickel, for instance, it appears that perfect conductivity would be reached at about 220deg. The small slope of the alloys is well marked, and the suggestion contained in the Paper on the relation between this slope and the purity of the metals is of great interest, and promises to be of no little importance.

While the resistances of pure metals converge, as Clausius suggested in 1858, towards absolute zero, a glance at Fig. 8, p. 614, shows that the curves of carbon converge to a high temperature. The abrupt change of state of carbon at its point of volatilisation, and the enormous apparent latent heat of carbon vapour suggest that at this temperature carbon, which then behaves as an electrolyte, undergoes an important change. It is apparent from the diagram and as well, indeed, from the tables, when attention is thus drawn to the figures, that the specific resistance of carbon diminishes $1{\cdot}23 \times 10^3$ to $1{\cdot}82 \times 10^3$ C.-G.-S. units per 1°C., taking the extremes only, since the curves are practically straight lines. At this rate the resistance would disappear altogether at 3020°, 3220°, and 3520°C., for the three varieties of carbon examined. Rosetti gave the temperature of the crater of the positive carbon at 3200°C. The admirable coincidence of this result with our calculations is unfortunately rather upset by an estimate by Prof. Dewar himself, of 6,000°C. as the temperature of the arc, but, coincidence or no, the result is at least suggestive.

The communication by Lord Rayleigh in the *Philosophical Magazine* for October on the intensity of light reflected from water and mercury at nearly perpendicular incidence, has too slender a connection with electrical science and engineering to warrant its reproduction in these columns, but one or two points in the experiments and the results are of considerable practical interest. The object of the research was a photometric comparison of a direct and of a reflected ray from a glow lamp. Photography was used, and the integration of the effect during an exposure of several minutes allowed the adjustments to be made with greater facility. Owing to veins in the glass bulb it was necessary to cover it with tissue paper, and as rays proceeding from the lamp in opposite directions were used, it was rotated slowly during the whole time of exposure. At first ordinary plates were used, but as these plates were scarcely sensitive to yellow and green light, the effective light was liable to considerable variation with the current used to light the lamp. Isochromatic plates were then employed, and a yellow glass was used. The spectrum was photographed, and was well defined, lying with almost perfect symmetry between the sodium and the thallium lines. The effective wave-length was, therefore, about 5620. Under favourable circumstances it was possible to detect a difference of $3\frac{1}{2}$ per cent. in the photographic records; a few experiments could, therefore, be expected to give the required result within 1 per cent. Lord Rayleigh's photographic method of photometry, the value of which depends on the observance of these simple but important conditions, may be expected to be of considerable value in ordinary photometric work.

With the reflective power of water, viz., 0·02076 to 0·022, as measured by Lord Rayleigh, we are not much concerned,

Digitized by Google

but the efficiency of mercury, 0·758, is of considerable importance in connection with the use of reflectors for electric light. It is not probable that reflectors coated with metallic silver are materially better than the best mirrors with mercury amalgam, and allowing for the glass and for tarnish, it must not be expected that more than 70 per cent. of the light falling on such reflectors can be returned. Accurative determinations of the reflective power, according to Lord RAYLEIGH's method, would be vitiated by very small departure from strictly plane reflectors; but a very small surface would suffice.

THE efficiency of metallic reflectors is not so important for practical purposes as that of silvered glass, because of their liability to tarnish. The following figures may, however, be of interest:—ZÖLLNER gave the reflecting power of mercury at 0·648; speculum metal, 0·535; glass, 0·040; water, 0·021. The last of these agrees well with Lord RAYLEIGH's determination, but there is a considerable divergence in the first. Sir J. CONROY found silver to be 0·70; speculum metal, 0·66; steel, 0·54 and tin, 0·4; but from the account of his experiments in *Proc.* Roy. Soc., XXXV. and XXXVI., he does not appear to have made his observations immediately after polishing the mirrors. HERSCHEL gave 0·6 as the reflecting power of mercury, and put silver as high as 0·91.

THE problem of the transmission of alternating currents along inductive cables was solved some years ago in a very complete manner by Mr. OLIVER HEAVISIDE in the pages of *The Electrician*. Several of the results then obtained have been re-proved in an article by Drs. BEDELL and CREHORE, the first part of which we publish in this issue, and the conclusions have been rendered more easily intelligible by means of curves, and by working out cases numerically. Complicated mathematics of the character here employed remains quite useless till it emerges from the symbolic form, and is reduced to actual figures. All formulæ which are useful are of a simple character; but until the practical conditions of a problem are thoroughly grasped it is impossible to foresee where approximations in the mathematical processes can safely be made. With alternating currents of ordinary frequency, the solution of Mr. HEAVISIDE can be much simplified, as was shown by Dr. FLEMING in a Paper read before the Institution of Electrical Engineers in connection with the so-called Ferranti effect. Indeed, it is obvious that, as the wave-length of ordinary alternating currents is about 2,000 miles, the conclusions of the present article regarding the effects happening at a distance of half a wave-length do not often apply on this planet. With the more rapid currents used in telephony the results became more applicable, though they have not yet been reduced to a form such that their truth can be easily put to a practical test. The problem of improving signalling on long telephone or telegraph cables is obviously one of great importance, and, unfortunately, theorists and practical men appear quite at variance as to the best way of seeking for improvement.

THE system of granting rebates to the customers of an electricity supply company, having for basis the number of units consumed *per lamp installed*, is undoubtedly the most equitable to the consumer and the most advantageous to the company, since it affords relief not only to the large but to the small consumer and tends to prevent the fixing of unnecessary lamps. But, as we remarked last week, discounts on all quarterly bills exceeding a certain minimum, although theoretically less correct, may in practice give more satisfaction, since it is possible to pay too high a price in the shape of a complex sliding scale for the boon of a perfectly fair tariff.

OUR objection to the Leeds tariff was first of all that the meaning of "supply demanded" was ambiguous; and that, presuming it meant total lamps installed, the high figure of 250 hours per lamp per quarter, or 1,000 hours per lamp per annum which had to be reached before any reduction was made in the standard price of 8d. per unit, rendered the proffered rebates somewhat illusory and, therefore, likely to cause dissatisfaction amongst consumers. Taking the experience of London supply companies, 10s. per annum per lamp connected may be considered an average income; this means at 7d. per unit a consumption of 17 units per annum, that is to say, each so-called 30-watt lamp connected to the company's mains is alight 566 hours per annum, or a little more than 1½ hour per diem.

FROM this it will be seen that the conditions at Leeds will have to be—as indeed they may—something totally different to those which obtain in London, if the average customer is to get his 10 per cent. reduction. At Exeter, on the other hand, as will be seen by Mr. T. P. WILMSHURST's table in another column, the first rebate is made when each lamp installed has been alight two hours per diem, so that in Exeter the average customer's bill may possibly be affected. The whole thing seems really too complicated, and hardly worthy of the attention of any but very large consumers, and these would, in any case, naturally make some sort of bargain.

THE Works Committee of the Dundee Gas Commission received a letter at their last meeting from Sir COURTENAY BOYLE, to whom, by-the-bye, *The Times* alluded repeatedly in a recent leading article as Mr. COURTENAY BOYLE. The *Dundee Courier* follows the example of *The Times* when quoting part of this letter, together with a number of rules and regulations for the erection and construction of fittings. The official letter from the Board of Trade approves of the system adopted by Dundee, but goes on to say that "in the case of a system of laying mains . . . in which the conductors consist of bare copper strips, supported on insulators in conduits, serious damage and even danger may result from allowing any accidental contact with earth to remain on the system." In connection with this warning it is worthy of remark that no case of damage or danger has been heard of where such mains have been laid according to the plans of the originator of the system, Mr. CROMPTON, but difficulties have in several cases beset those who have followed his lead.

THE rules, which were published in the local journal to which we have alluded, appeared at first sight to have

Digitized by Google

emanated from the Board of Trade. We gathered from some remarks of the Chairman at the meeting of the City of London Electric Lighting Company on September 1st, that the Board of Trade contemplated the publication of yet another batch of rules, relating this time to arc lights and motors. But on making inquiry yesterday at the Electrical Department we were informed that nothing was known of these rules, and they have therefore been drawn up and promulgated apparently upon the responsibility of the Gas Commission of Dundee. The Dundee decrees forbid the wiring of gas fittings, and go into details about the fixing of meters. The cost of making a connection and fixing meter and cut-out is put at 5s. Motors are to be insulated from earth. Where arc lamps are to be "often turned on or off, a resistance must be provided to reduce the rate at which the current is thrown on." Sundry rules are made about the insulation of arc lamps and even of the holders of glow lamps, where these are used on lamp posts. The carrying out of all these paternal precepts will, of course, go on smoothly, for everything is to be done "to the satisfaction of the inspector."

Owing to pressure on our space we have been again compelled to hold over an article by Lord Kelvin, P.R.S., entitled, "To Draw a Mercator Chart on One Sheet, Representing the Whole of any Completely Continuous Closed Surface." For the same reason a lengthy letter from Mr. C. E. Kelway in reply to one from Lieut. Bacon, R.N., which appeared on page 595 of our last issue, has been kept back until next week.

The Edison Lamp Patent.—This Patent has been upheld by the United States Supreme Court.

Middlesborough.—The Town Council have decided to apply for an Electric Lighting Provisional Order.

The Endowment of Science.—The Conseil Général de l'Isère have voted £20 towards the foundation of a course of electricity at the Grenoble Faculté des Sciences.

St. Marylebone Vestry.—The Works Committee of this Vestry have under consideration the desirability of adopting electric lighting in the main streets of the parish.

The North Metropolitan Tramways Company.—At their last meeting the London County Council decided by 92 votes to 24 to purchase a portion of this Company's system.

Accrington.—At a meeting on Monday last the Town Council sanctioned the scheme for the purchase of land, and the erection, at a cost of under £10,000, of an electric lighting station.

Stuttgart.—The electric tramway built by the Allgemeine Elektricitäts Gesellschaft in Stuttgart has been completed, and is now being worked for the stipulated period of three months before being taken over by the authorities.

Obituary.—We regret to announce the death, at the age of 63, of Dr. Alexander C. Kirk, senior partner in the firm of Messrs. Robert Napier and Co., shipbuilders, of Glasgow, well-known as constructors of the principal cable ships.

Manchester.—A deputation of members of the Manchester Corporation visited Glasgow last week for the purpose of getting information as to the gas and electric lighting undertakings which the Glasgow Corporation have under their charge.

Glasgow.—The Electric Lighting Committee expect to be in a position to begin supplying current from the new station to private consumers not later than December 1st. It is further expected that the illumination of the principal streets in the central district of the city will be accomplished before the close of this year.

Military Projectors.—Experiments have recently been carried out at St. Petersburg on the illumination of the ground surface by means of electric projectors placed on a balloon floating at a height of nearly 2,000ft. More exhaustive tests will shortly be carried out at some forthcoming siege operations at Ivangorod.

Blackpool.—According to a statement made at the Town Council on Tuesday, the arrangements for providing the town with the electric light are near completion. A tender of £18,709 for the whole of the plant was accepted by the Council, who intend to use the same dynamos for running the trams during the day and for generating current at night.

Inter-urban Telephony in Australia.—The establishment of telephonic communication between Melbourne, Sydney, and Adelaide has been reported against by the Inter-Colonial Postal Conference. The initial cost of the line between Melbourne and Adelaide (350 miles) was put down at £18,223, and the annual outlay necessary at £3,233; for the line between Melbourne and Sydney (400 miles) the estimated cost was £18,000, and the annual outlay £3,200.

Electric Lamps for Customs Officers.—In order to avoid the possibility of explosion while searching for contraband goods on board tank and other vessels carrying petroleum or explosives, the Customs officers are in future, by order of the Customs Board, to be supplied with electric lamps of a special pattern. Ruby-coloured lights for the examination of imported cases of photographic negatives in a dark chamber are also to be supplied to obviate the risk of premature development.

The Cape Colony Telegraphs.—The Postmaster-General of Cape Colony, in his report for the year ending July last, states that the revenue of his department was £250,056, being £14,500 over the revenue for 1891. The only decrease was £1,227 in telegraph receipts, which fell to £66,761. The number of paid messages, 839,292, and of Government messages, 104,049, showed a decrease of 13,965 and 5,581 respectively; but the railway messages, 377,402, showed an increase of 29,812.

Copper.—On the 30th September the total stocks in England and France and the shipments advised from Chili and Australia aggregated 58,482 tons, against 59,718 tons on the 31st August. This diminution has been caused by a falling off in supplies rather than by an increase in deliveries. The former were only 7,132 tons—with one exception the smallest monthly aggregate in the present year. The deliveries are returned at 8,368 tons—also, with one exception, the smallest of the year.

Steel Trolley Wires.—A recent extension of the electric street railway system of Ottawa, Ont., is made interesting says the *Western Electrician*, by the use of steel instead of copper for the trolley wires. Sliding instead of rolling contacts are used, and it is intended to ultimately use copper cross wires from the feeders instead of steel, as at present. The idea is to make use of a harder metal to withstand the friction of the trolley contact, and to make up for the loss of conductivity resulting from this substitution by the use of copper instead of steel cross wires.

A Curious Lightning Discharge.—In a letter to *Nature* Dr. Oliver Lodge reports that on July 3rd last what was described as a fire ball was seen to strike the ground near the lake in Sefton Park (Liverpool), a column of water about 60ft. high being shot up from the lake itself. On examining the spot, holes 4ft. deep and from 7in. to 2in. in diameter were found, terminating in a drain pipe which was shattered. It seems curious that the lightning should have made use of a drain pipe 4ft. below the soil to get at the water of the lake. The spot struck was a simple grass slope about midway between a tall boathouse and a drinking fountain; small trees were also in the neighbourhood.

Lectures to Electrical Trades Artizans.—A local branch of the Electrical Trades Union has been formed at Glasgow, and by way of showing that it is sought to make the members

Digitized by Google

proficient in their work, the Union Committee has organised a course of lectures on trade subjects for the ensuing winter. The course will be inaugurated next month by Mr. H. A. Mavor, M.I.E.E., and on that occasion Lord Kelvin will preside. The other lectures, which are to be given monthly, are to be delivered by Mr. Rankin Kennedy, Mr. Sam. Mavor, Mr. William McWhirter, Mr. W. B. Mountain, and Mr. R. D. Smillie, all of whom are closely identified with the electrical industries of Glasgow and the West of Scotland.

Artificial India-Rubber.—Dr. W. A. Tilden discovered some months ago that isoprene, which can be prepared from turpentine, under certain circumstances changes into what appears to be genuine india-rubber. Bouchardat had also found that the same change could be brought about by heat. The material so produced resembles pure Para rubber in every way, and, whether it is genuine rubber or not, it may be equally good for all practical purposes. It vulcanises, for instance. It, therefore, seems possible, says *Industries*, that we may soon be able to make india-rubber commercially. If this is possible, a fortune awaits the inventor who can make good rubber from turpentine at a reasonable price. It is a subject well worthy of the devotion of prolonged labour.

The Scott Flash-Signalling Lantern.—The Brazilian cruisre "Tiradentes," built and equipped at Elswick, went through her trials a few weeks back. After the trials the signalling lamp, invented by Commander Scott, of H.M.S. "Excellent," was exhibited and created great interest. The lamp in question, which was described in *The Electrician*, Vol. XXV., pp. 171 and 473, is designed to send signals by the usual flashing method. The lamp can be placed on the top of the mast, or on a special signalling pole; an all-round sphere of action is therefore afforded to it. The operator, however, can be posted wherever convenient. He works the lamp by means of a key. Each time the key is pressed the lamp emits a flash, shutters surrounding a glow lamp being actuated by a system of electro-magnets.

Prize for a Microphone.—*Nature* announces that Baron Léon de Lenval, of Nice, offers a prize of 3,000 francs to the inventor of the best application of the principles of the microphone in the construction of a portable apparatus for the improvement of hearing in deaf persons. Instruments for competition should be sent to Prof. Adam Politzer, or Prof. Victor von Lang, Vienna, before December 31, 1892. The prize will be awarded at the Fifth International Otological Congress at Florence in September, 1893. If no instrument is judged worthy of the prize, the jury reserve the right of announcing another competition, unless Baron Lenval decides to dispose of the prize otherwise, The following are the members of the jury:—Prof. Adam Politzer (President), and Prof. Victor von Lang, Vienna; Dr. Benni, Warsaw; Dr. Gellé, Paris; Prof. Urban Pritchard, London; Prof. St. John Roosa, New York; Prof. Grazzi, Florence.

The Franklin Institute (Philadelphia).—We have received an advance proof of the programme of lectures at this Institute for the season 1892-93. Amongst the lectures we note the following ones of interest to electrical engineers:—November 21st, Mr. G. H. Babcock, "The Genesis and Exodus of Steam;" December 2nd, Mr. J. M. Dodge, "Rope Power Transmissions;" December 12th, Mr. T. C. Martin, "Electricity in the Modern City;" December 19th, Mr. George Faunce, Superintendent Pennsylvania Lead Company, Pittsburg, Pa., "Electro-Metallurgy and its Applications to Silver Refining and Incidentally to other Metals;" January 2, 1893, Mr. Pedro G. Salom, "The Storage Battery Question;" January 23rd, Dr. Louis Duncan, "Electric Power Transmission;" February 6th, Mr. Elmer G. Willyoung, "Electricity and the Ether;" February 24th, Mr. Nikola Tesla, "An Experimental Study of Light Effects Propuced by Alternating High Potentials;" February 27th, Mr. Clayton W. Pike, "How we Measure Electricity."

Scarborough.—At a special meeting of the Town Council held last Friday, the minutes of the Sanitary and Lighting Committee, which contained a report of the Electric Lighting Sub-committee, were adopted. The principal clauses in the report were to the effect that Mr. A. A. Campbell Swinton should be allowed to form a company to take over the powers granted to the Corporation in 1891, such company to be formed within a period of eight weeks from October 1st. The Corporation are to have the option of acquiring the undertaking at the end of 21 years upon paying for the undertaking as a going concern including goodwill (but without any allowance for compulsory purchase), such valuation to be made on a basis that the powers of the Company will cease at the end of the thirty-second year, and upon the further basis that the dividend paid by the Company shall be taken not to have exceeded a cumulative dividend of 10 per cent. The maximum price of current for public lamps is to be 6d. per unit, with sliding scale reductions, after payment of an 8 per cent. dividend, and after making due allowance for depreciation and reserve. The maximum price of current to private consumers is to be 7d. per unit.

Carlow.—The *Journal of Gas Lighting* has the following remarks with reference to the Carlow incident reported in our issue of September 23rd:—

We should like to know if the facts are as stated. If so, it will only mean that somebody connected with the Carlow Gas Company has displayed a not unnatural result of mental aberration, superinduced possibly by some troublesome consumer who has been playing fast and loose between gas and electricity. There is not the remotest chance that the same performance will be repeated in any considerable town. Gas managers in general are a patient, long-suffering race. They know that their duty is to "take a back seat" whenever an electric light speculator comes into their district. They must abide in patience when the new electric lamps flaunt their hardest in the most conspicuous shops, and must allow the gas-meters to remain for the purpose of a stand-by in case anything goes wrong with the electricity. They must, without grumbling, rest content with such crumbs of rental as meters thus used bring in; and on no account must they hint that this kind of treatment strikes them as "not good enough." It is not only for the pleasure of electricians that gas companies are called upon to fill the part of the "friend in need." Whenever a local authority thinks fit to play for awhile with street oil-lamps, the gas company must pretend to take no heed, but must go on making every necessary provision in case the authority should decide to fall back upon gas at a day's notice. In the case of powerful gas companies the irritating vagaries of a few consumers do not disturb the even tenor of the way of the management; but in small places gas directors and managers, who remember that gas supply is only a business like any other, and who are not devoid of tradesmen's jealousy, are apt to act occasionally like angry men do all the world over in and out of gas works—that is to say, hastily and mistakenly.

Printing Mathematical Symbols.—The following letter from Prof. Silvanus Thompson, which appeared in *Nature* of September 29, will, we hope, appeal to that ever-increasing multitude of individuals who write incomprehensible equations in undecipherable symbols:—

Everyone who has had to correct printers' proofs of mathematical formulæ must be painfully alive to the pitfalls into which the non-mathematical compositor continually blunders. To such as know the extreme difficulty of getting such formulæ properly set up there have doubtless occurred from time to time suggestions for such simplifications of notation as shall render the composition less liable to derangement. One most sensible step of the kind I allude to is the introduction by Sir G. Stokes of the solidus notation for quotients, whereby

$$\frac{dy}{dx} \text{ is now written } dy/dx.$$

The immediate purpose of this letter is not to propound any wholesale scheme of reform, but to advocate one other simple step, and to induce some of my *confrères* to give the world their own suggestions.

Exponentials are a continual stumbling-block to the compositor, and to the printer's reader, who, when he comes to an expression like

$$Ae^{-ax}$$

does his best to make it look a little straighter, and turns it into

$$Ae^{-ax},$$

or into

$$A_e{}^{-ax},$$

or perhaps worse.

The reform I advocate is to write the thing as follows:—

$$A\ exp[-ax],$$

the square brackets being possibly omitted in all cases when their omission would occasion no confusion. One gain in this notation is the reduction of the whole of the symbols to one level, so not breaking the line of type.

Another useful reform, though one on which I fear the probability of agreement is less likely, is the use of the Continental notation for inverse trigonometrical functions, writing, for example,

$$\text{arc tan } x,$$

instead of

$$\tan^{-1}x$$

for the angle whose tangent is x. Our notation is not only liable to continual misprinting, but is very confusing to Continental readers, who again and again read the latter expression as meaning

$$(\tan x)^{-1}, \text{ or cotan } x.$$

I have even seen it reprinted in a German technical journal as

$$\tan - 1x.$$

THE MEASUREMENT OF HYSTERESIS AND EDDY-CURRENT LOSSES IN TRANSFORMERS.

BY SYDNEY EVERSHED AND ERNEST B. VIGNOLES.

(*Concluded from page 587.*)

II.

Comparison of Observed with Calculated Loss.

In order to compare this observed loss with that calculated from the B.H. cycle obtained by our ballistic-galvanometer method added to the calculated waste by eddy currents, the transformer was put through the cycle referred to with the following results, care being taken that the maximum induction density was the same as that in Experiment II.

Experiment III.—B.H. *cycle.*

Transformer used in Experiment II. wound with $P_1 = 20$ turns; $P_2 = 40$ turns; secondary = 300 turns.

Table II.

Rising.		Falling.	
Total mag. force.	Total induction.	Total mag. force.	Total induction.
− 126	930	228·0	43,100
− 75·5	1,460	111·0	42,400
− 25	2,720	+10	40,000
+ 30	7,450	− 25	35,800
+ 49·4	15,500	− 55·5	25,900
+ 77·6	29,000	− 56·0	25,400
+112·0	36,400	− 63·0	22,400
+144·0	39,000	− 90·7	12,500
+231·0	42,800	− 87·6	13,350

These results are plotted as a curve in Fig. 7. In order to give the loss per cubic centimetre per cycle, for comparison with other curves, the curve has been plotted from the co-ordinates:—

$$H = \frac{\text{Total magnetising force}}{\text{length of iron path}};$$

$$B = \frac{\text{Total induction}}{\text{area of iron}};$$

but these co-ordinates have no physical meaning, as the length of the induction path varies nearly 100 per cent.

The falling curve is only taken to see if the difference in area due to time lag amounts to much in this sample. The curve plotted is obtained by folding back the rising curve in the manner described. Note the time-lag at the top reading. On "make" the induction is 42,800, while on breaking, although the current has fallen to 228 from 231, the induction is higher, 43,100.

The area of this curve is a measure of the average loss per cubic centimetre in the ring due to hysteresis, when the iron is carried through its cycle in about two seconds, as explained in connection with Fig. 3.

Calculating the work from the area of the curve by the formula—

$$\text{Total work in ring} = \frac{\text{area of curve}}{4\pi} \times \text{volume of ring.}$$

$$= 443{,}000 \text{ ergs per cycle.}$$

Therefore, at 100 ∿, the loss would be $4{\cdot}43 \times 10^7$ ergs per second, or 4·43 watts.

Calculation of Eddy Current Loss.

The eddy current loss was calculated from the following formula:—

$$W = \frac{\pi (\dot{B})^2 t}{6 n \rho \log_e \frac{R}{r}}$$

Where $(\dot{B})$ = effective rate of change of total induction (in volts).
t = thickness of each lamina in ring.
ρ = specific resistance of the iron in ohms.
R = outer radius, r = inner radius } of the ring.
n = number of laminæ.

(A proof of this formula will be found at the end of the present article.)

Substituting the following values in the above equation; namely:—

$$(\dot{B}) = \frac{4{\cdot}4 \times \text{total induction} \times \text{frequency}}{10^8} \text{ volts,}$$

$$= \frac{4{\cdot}4 \times 21{,}300 \times 100}{10^8} \text{ volts,}$$

$$= \frac{9{\cdot}37}{10^2} \text{, volts,}$$

$t = 0{\cdot}0414$ cm.,

$\rho = \frac{13{\cdot}5}{10^6}$ ohms, (average of 3 determinations of actual iron used),

R = 4·64 cm., r = 2·08 cm., $\log_e \frac{R}{r} = 0{\cdot}803$,

$n = 20$,

we find the total energy spent in eddy currents in the core is

$$W = 0{\cdot}88 \text{ watts.}$$

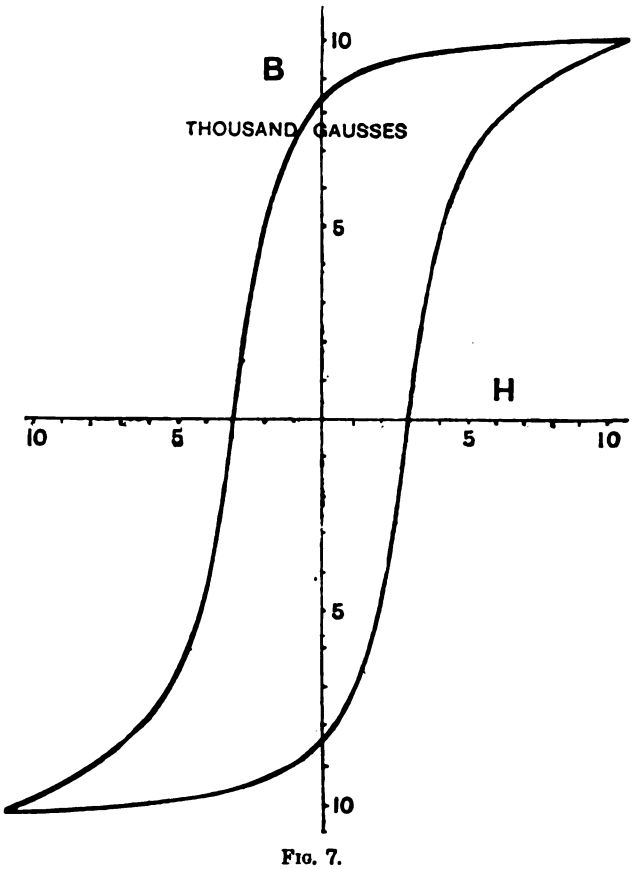

Fig. 7.

As we point out at the end of this article, this value is, for several reasons, slightly too high; but since it is only one-sixth of the total waste, an error of 6 per cent. in the estimation of the eddy current loss will only produce one of 1 per cent. in the total.

Adding these two figures, 4·43 and 0·88 watts, we get the total predicted loss, on the assumption that the work done in overcoming hysteresis at a frequency of 100 ∿ is the same as it is found to be by measurement at a frequency of about 0·5 ∿.

We have, then,

Hysteresis loss	= 4·43 watts
Eddy currents	= 0·88 „
Predicted total	= 5·31 watts
Measured total by thermometric method	= 5·40 watts
Difference between observed and predicted loss	= 1·8 per cent.

Digitized by Google

Practical Conclusions.—The result just given will, we venture to hope, finally set at rest the vexed question of magnetic time-lag, so far as it affects electrical engineering.

Clearly the difference in the work done in carrying a piece of iron through a complete magnetic cycle in periods even so widely different as 2 seconds and 0·01 second is too small to be detected with certainty by the methods of experiment employed—it cannot possibly be greater than 4 or 5 per cent., and is probably under 2 per cent.; in other words, in designing a transformer or an alternator the hysteresis can be determined with abundant accuracy from the cyclic curve, of a sample of the iron to be used, taken by a ballistic galvanometer method. If the method used in our investigations is adopted, and the rising curve of induction only is used, no correction for time-lag is required; if, however, a method of testing is employed involving a necessarily slow cyclic period —of the order minutes rather than seconds—an indeterminate error is introduced which may amount to 20 per cent. or more of the estimated loss.

Another important conclusion should be drawn from our results by engineers, and that is that every one of the published tables of hysteresis losses for "charcoal iron of good quality" is a trap for the unwary. Prof. Ewing was, we

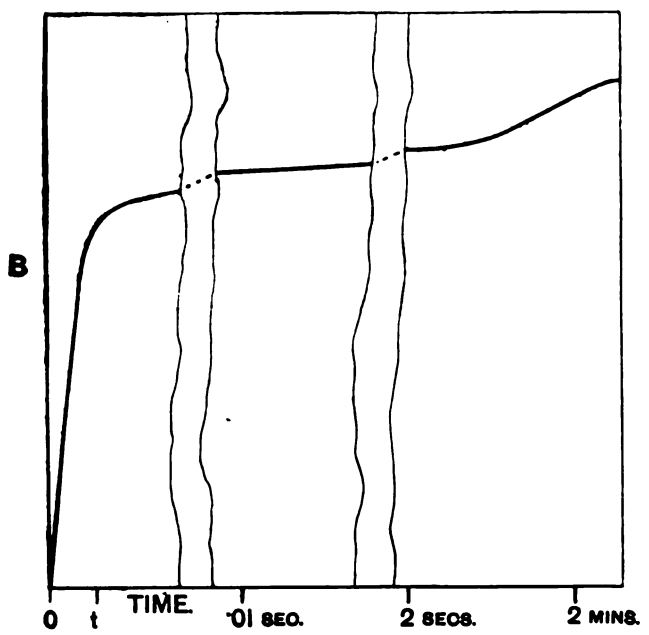

FIG. 8.—Curve illustrating Growth of **B** in Iron with time after application of **H**. t represents a time comparable with the vibration period of an iron molecule.

believe, the first to publish such a table, and his figures have been almost universally copied and adopted. Unfortunately no material is more variable in its qualities than the so-called "charcoal iron," and Prof. Ewing's results can only be held to be true for the particular samples which he used.

Mr. Alexander Siemens, Mr. Swinburne, and, since writing this article, M. Dobrowolsky have all published tests showing far higher hysteresis losses in iron than those given by Prof. Ewing; for example, Mr. Siemens found the waste some 70 or 80 per cent. in excess, and M. Dobrowolsky confirms this result. We have ourselves tested samples of charcoal iron which gave results about 20 or 30 per cent. above those of Prof. Ewing's table, but the transformer core used in the present experiments has a hysteresis waste about 90 per cent. in excess of Prof. Ewing's iron; and it must be distinctly understood that this iron and the sample just referred to were made at the same mills, sold as the same quality, and have nearly the same permeability. So that unless a manufacturer of alternators and transformers is prepared to leave the temperature of the cores to chance, letting them vary as much as 100 per cent., he must test every batch of iron sheet or wire received from the mills. The same remarks apply but of course with less force to the armature cores of direct current dynamos.

The introduction of some simple and direct method of testing samples of iron for hysteresis waste would go far towards securing more attention to quality on the part of iron manufacturers, with the natural result of greater uniformity, and we shall no doubt see the day when it will be as much a matter of course to buy and sell iron on a specification of "not more than 6,000 ergs per cc. per cycle," as it now is to specify for copper of 98 per cent. conductivity. Prof. Ewing is already in the field with a magnetic curve tracer, and his ingenious device is probably the "Puffing Billy" of magnetic testing; the "Rocket" has yet to be built.

So much for practical results. We may just emphasise the theoretical point of interest which is very clearly indicated by the experiments described. When we trace a cyclic curve very slowly—taking, say, a minute or so to complete one cycle, the curve has a certain area—to fix our ideas, say an area of 100. When we use the method already described in which the iron completes its cycle in about two seconds, we find the area has increased to about 120, but by decreasing the time to $\frac{1}{100}$ second, we do not appreciably add to the area; it is certainly not increased to more than 125.

Evidently, then, the creeping up of the induction is a slow process, for the value of the induction is practically the same after two seconds as it is after 0·1 second; but give the iron a minute or so and the magnetic chains slowly break up and the induction as slowly increases. The question naturally presents itself, would the value of the induction one-millionth of a second after the application of the force differ from that after one-hundredth of a second? The experiments hardly do more than suggest an answer, but it seems unlikely that any appreciable difference would be found until the interval of time approached the value of molecular vibration-periods. In Fig. 8 we give a curve which is a rough illustration of this view of the relation between the value of **B**, and time after application of **H**; the curve has, of course, no pretence to scale or proportion.

In this connection "molecular vibration-periods" must be understood to mean periods of the *magnetic* molecule, or *Ewing particle*, which is not necessarily identical with the chemical or physical molecule; and by exploring the hypothetical curve in Fig. 8 towards zero we might arrive at some quantitative idea of the structure of magnetic substances.

Appendix.—The formula used in the preceding article for the calculation of eddy current losses may be obtained as follows:—

Consider one stamping of the core, of inner and outer radius r and R and t cms. thick; let the axis of figure be the axis of x; any radial line bisecting the section of iron the axis of y.

Then, if M be the magnetising force due to the exciting current, the induction *density* at any radius y is

$$\beta = \frac{\mu M}{2\pi y},$$

and the E.M.F. in an element dy, dx, $y\,d\theta$ is

$$E = \dot{\beta} \times \text{area} = \frac{\mu \dot{M}}{2\pi y}\, x\, dy.$$

The resistance of the element is $\frac{\rho\, dy}{y\, dx\, d\theta}$, so that the power spent in it

$$dW = \frac{\mu^2 \dot{M}^2 x^2}{4\pi^2 \rho y}\, dy\, dx\, d\theta,$$

and the power spent in the whole stamping is

$$W = \int_0^{2\pi} \int_{-\frac{t}{2}}^{+\frac{t}{2}} \int_r^R \frac{\mu^2 \dot{M}^2 x^2}{4\pi^2 \rho y}\, dy\, dx\, d\theta$$

$$= \frac{\mu^2 \dot{M}^2 t^3}{24\pi\rho} \log_e \frac{R}{r} \quad \ldots\ldots\ldots \text{(i.)}$$

But actually not M, but the *total* induction (**B**) was known. Now,

$$(B) = \int_r^R n\, t\, \beta\, dy = \int_r^R \frac{n\, t\, \mu M}{2\pi y}\, dy = \frac{n\, t\, \mu M}{2\pi} \log_e \frac{R}{r} \quad \text{(ii.)}$$

Digitized by Google

where n is the number of stampings in the core. Combining I. and II. we find for the power in the whole core

$$W = \frac{\pi t (\dot{B})^2}{6 \rho n \log_e \frac{R}{r}} \quad . \quad . \quad . \quad . \quad . \quad (iii.)$$

the formula which has been used in the text.

Several assumptions have been made in arriving at this result.

First that $\beta = \mu H$,

that is say, that the induction density is proportional to the magnetising force; we know that it is not, but the density is so low that no appreciable error is introduced; we are dealing with total induction only, and a different distribution of that total in the section hardly affects the result.

Secondly, we assume the magnetising force to be the same at the centre of a lamina as it is at the outside. A formula recently given by Prof. J. J. Thomson shows that it is really about 2 per cent. less; but here again the fact that the induction is a little displaced towards the outside of the iron diminishes the power spent by an entirely negligible amount.

Thirdly, we assume the conductivity of the lamina at right angles to its plane to be infinite, and this also tends to make the formula give too high a result, the error being of the *order* 2 per cent. in this case.

Now as an error of 6 per cent. in the estimation of the eddy current loss only leads to an error of 1 per cent. in the estimated value for the waste due to hysteresis and eddy currents together, it is clear that all these assumptions are justified. We must remember that the result given by the formula cannot possibly be too low, but *may* be 2 per cent. too high. To the non-mathematical mind the fact that the calculated differs from the measured loss by less than 2 per cent., will be the most satisfactory proof of the accuracy of the formula.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 559.*)

19. Final Splice and Completion of Repair.—The end of cable just unmoored from buoy and secured on board is now connected up to testing-room for the purpose of communicating with the shore on that side. It will be remembered that at the time of first cutting in, before buoying, the electrician instructed this end to keep watch day and night after a certain day and hour, decided by him to be about the time the ship would fetch the buoy on her return. In the old days of single cables the station whose end was buoyed was, per force, in ignorance of all that might happen to the ship during picking up and repairing, and only learnt the news upon her return to the buoy after finishing the repair. The staff would, accordingly, commence to keep watch after the specified hour, generally preferring for this purpose the mirror instrument, in which the beam of light thrown onthe wall is an effective means of attracting the attention, the slightest movement of the beam being noticeable, without the necessity of always being close to the instrument. Day and night the spot of light would be watched, three men taking it in turn to relieve each other during the twenty-four hours, and frequently, owing either to bad weather or special difficulties encountered by the ship in picking up or localising, they might be kept at this for several days, without any idea of how matters were progressing at sea. "No signs of ship" was probably a more frequent entry in the diary in those days than in the present days of duplicate cables, for now the station whose end is cut and buoyed at sea can still learn *viâ* the duplicate cable what the ship is doing, and by this means the time spent in keeping watch is very greatly reduced, for the ship does not require watch kept until she notifies by the other cable that she is up to buoy.

Speaking of interrupted communication, whether caused by the ship cutting in for repairs or a break in the cable, there is a very great contrast on important lines between the old *régime*, say of 10 years back, with only one cable, and the present with two or three to depend on. That curious experience for an important foreign or colonial seaport town to undergo, namely, to have its telegraphic communication with Europe and the civilised world completely severed for days together, is now of very rare occurrence, and we have grown so accustomed to look into our papers for news of what has occurred only a few hours ago in the remotest regions of the globe, and the commerce of the world is so largely controlled by telegraph that the habit of rapid intercourse has become a second nature, and a total interruption affects an increasingly large section of the community.

Looking back for a moment on the interruptions occurring in the days of single cables it was the usual custom to bridge over the period of interruption by sending the accumulated "through" messages on by the first steamer leaving; or if none were about to proceed that way, by one chartered specially. On the arrival of such a budget at a station there was no small excitement to transmit the same onwards at the utmost speed attainable by the operators' skill, and the capacity of the lines. Copies of all messages were, of course, kept, because the cable might be put through while the chartered vessel was on the high seas, and in that case she would be landing a batch of messages already delivered at their destination thousands of miles away, days ago. But it often happened that an interruption lasted long enough to allow several batches to cross each other by sea before communication was restored. As concerned the "local" traffic, or that immediately confined to the interrupted stations, people either posted their messages by mail or by the chartered steamer, but it was curious to notice that some whose news was of greater importance preferred to pay the piper and gain the two, three, or four days, as the case might be, by sending their messages round the other way. As the result of this there was something inconceivably odd in transmitting a message, say from Bombay to Aden, on its way to London from Hong Kong, its ultimate destination being Shanghai.

The sender of such a message would probably gain three days over the mail between these two ports in China. But it is curious that in getting from one port to the other the message would pass twice over the continents of Asia and Europe by different routes, the return route being by the Siberian lines and Vladivostock. The two ports in China above mentioned have now triplicate communication, two cables and one land line, and most lines are either directly duplicated or the duplicate cable is taken by a different route in order to call in at fresh places on the way. With such wise provision it is extremely rare nowadays to hear that any important town or colony is totally interrupted. Such can only be conceived to occur in the event of a volcanic upheaval affecting cables lying in the same region, as happened in the year 1890, on the night of July 10th, when the three cables between Java and Australia were simultaneously interrupted near the former island. There exists, of course, a large number of single cables which it would not pay at present to duplicate, but the foregoing allusions have been made to what might be called the great trunk systems connecting China, Japan, India, Australia, America and Africa with the continent of Europe.

But to return. The ship, having called up the buoyed end asks for "Free 30 seconds," in order to prove insulation good, and then "Earth 30 seconds," to ascertain correct resistance of conductor and distance from shore. Likewise, having cut the end of payed-out cable to allow sufficient length for splice, this end is connected to testing-room, and a similar "free" and "earth" taken. This gives the correct length of the line in ohms, and is compared with the length of cable in knots as increased by the repair. Sometimes the capacity is measured as well, but only if there has been some doubt about it in a recent localisation test. These tests finished, a message is sent to headquarters in terms somewhat as follow:—"Communication restored; now make final splice and return." It happens sometimes that a fault has broken out in some other cable and that instructions are sent to the ship to proceed thither as soon as she has completed this one. The electrician also sends the

*. All rights reserved.

Digitized by Google

message "Free one hour, then look out" to the superintendents at each station to cover the time for making the joint and splice. Meanwhile the revolutions of the drum during paying out, as seen by the rotometer, are noted, from which the length of cable payed out is calculated. This will exceed the length picked up by a small amount, and is worked out to three places of decimals, and the record of the length of cable corrected accordingly. Further, while the splice is being made a sounding is taken, with specimen of bottom and the temperature; also the latitude and longitude of the position is entered in the log, together with the type of the two ends of cable joined together.

Turning now to the splice, it has been observed that both ends are stoppered at the bows, and further secured by slip ropes stoppered to the cables at C C (as in Fig. 70), and wound round the bollards at B B. The joint and splice are, of course, similar to others, and have previously been described, but the writer takes this opportunity of describing what is called the overlapping splice, which is in very frequent use on repairs. The sketches in Figs. 69 and 70, relative to this subject, have been kindly supplied by Mr. F. C. H. Sinclair, of the Eastern Telegraph Company. For this splice the sheathing wires on one end, which we may call the left wires, are opened out for a length of 50ft. or 60ft., and the core so exposed cut away so as to leave only about three feet for jointing. The sheathing wires on the other side

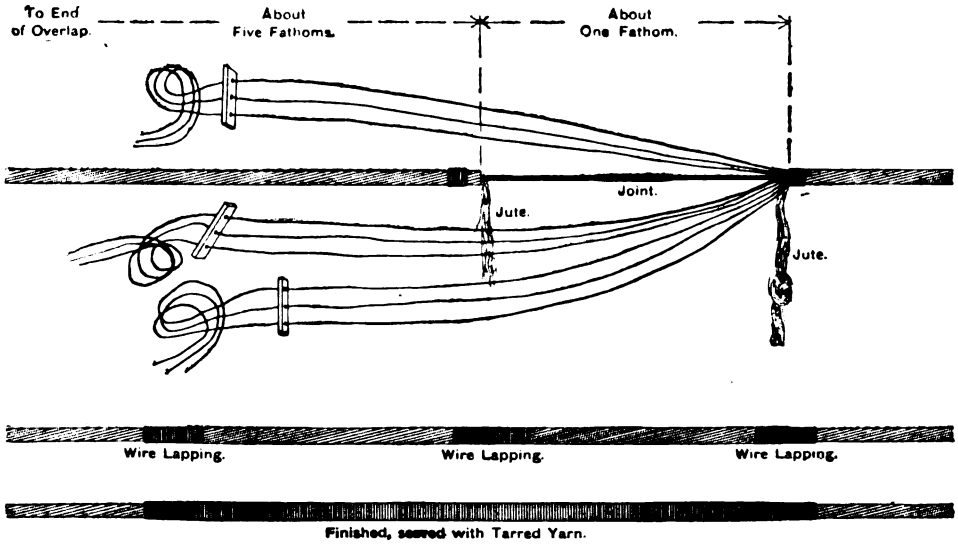

Fig. 69.—The Overlapping Splice.

—the right wires—are then cut off at a distance of about three feet, the ends being bound round with a piece of twine or yarn to prevent them opening out. This leaves three feet of core exposed on this side. The joint in the core is then made as previously described, and the jute serving, of which a sufficient length has been retained on the cable, is wrapped round it and the bare part of core. The splice between the sheathing wires is now made. The left wires are

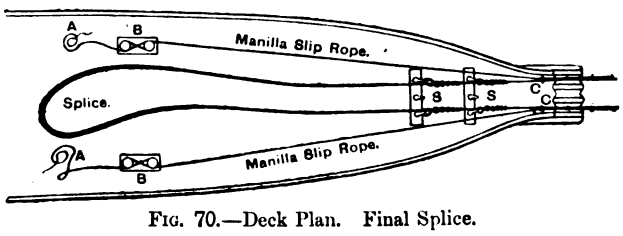

Fig. 70.—Deck Plan. Final Splice.

taken and divided for convenience in handling into bunches of three or four wires each, and in order to keep them always in the same position abreast of each other the ends of each bunch are given a twist or threaded through holes in small wood cleats, and then twisted (Fig. 69). This also gives something for the hands to lay hold of and pull on while laying the wires. The ends of the bunches are now taken in hand, and the wires laid spirally over the jute, all the wires coming properly abreast in their right positions. This first covers the joint and core, and has to be done gently until the wires are laid as far as the ends of the right wires. Then, with the assistance of the splicing tool, the wires are overlapped firmly over the sheathing of the other end, and as this proceeds soft iron wire is bound round at intervals to keep the wires in place. The splice is also tapered off by cutting away the ends of the wires at different lengths, and the whole is then served over with tarred yarn by means of serving mallets. This gives the splice a neat finish, and further increases the adhesion between the sheathings. The sketch represents first the wires opened out ready to make the splice; second the overlap as finished, with wire serving at intervals; and third, the finished splice, yarn served.

Splices are usually from 6 to 10 fathoms in length, the shorter splices being for types used in shallow water, and therefore not exposed to much strain. It is found in some types that when the wires are of iron they can be laid quite as firmly and well by hand without the aid of the splicing tool, and this is often done; but in cable of type C, where the sheathing is made up of wires alternated with yarns, or in types having sheathing wires of stiff springy steel, the work is much facilitated by the tool.

The overlapping splice just described is most often made when the two ends of cable are of different types, or, though of the same type, when they differ in lay. The lay of a cable is the distance, measured in the direction of the cable's length, in which any one sheathing wire makes a complete turn round the core. The longer the lay the less the length of sheathing wire to a given length of cable. For instance in a cable of 7in. lay, having a diameter of $1\frac{1}{2}$in. (that is, the diameter of what might be called the pitch circle of the sheathing wires, or a circle passing through their centres), each wire would be $8\frac{1}{2}$in. long in one lay, or $8\frac{1}{2}$ miles long in seven miles of cable; while in the same length of deep sea type having a 10in. lay there would only be $7\frac{3}{4}$ miles. These calculations depend upon the fact that the proportions between the length of a complete spiral, the corresponding length of cable, and the circumference of the pitch circle are the same as the hypothenuse, perpendicular and base respectively of a right angle triangle. This can be easily understood by wrapping a rectangular piece of paper once round a cylindrical surface such as a ruler. After cutting the paper or folding it so that the edges just butt on the surface, a spiral line is drawn from one end of the paper to the other, starting from the seam at one end and coming back to it at the other. Taking the piece of paper off and straightening it, it is seen that what was the spiral line is now a straight line from one corner to the other, and the ratios as given above are at once apparent. Hence in the above example the mean circumference being 4·7in., the square of the hypothenuse, or the spiral, is equal to the sum of the squares on the perpendicular and base or $7^2 \times 4{\cdot}7^2 = 71$, and the root of this

Digitized by Google

is 8½in., which is the length of sheathing wire in one complete lay of 7in. in a cable of this size.

In the splice just described the wires on the left are not picked out in alternate pairs to leave spaces in which to lay the right wires. While this system of picking out and laying in makes a neater job and binds the wires together better, it cannot be done when the cables are of different types or lay, and the overlapping splice has proved itself thoroughly reliable when made in sufficient length to suit the type of cable, and it also takes less time to make than the other.

The splice being complete has now to be slipped overboard. For this purpose the stoppers are cast off and a turn or two of the slip ropes round the bollards taken off, while two gangs of men stationed at A A (Fig. 70) stand by the slip ropes and ease them away carefully, taking care to do so at equal speed. The weight of the bight of cable as it descends of course exerts a considerable pulling force on the ropes, but the turns round the bollards easily hold it, and the slip ropes can be eased away to a nicety. As the end of the ropes stoppered

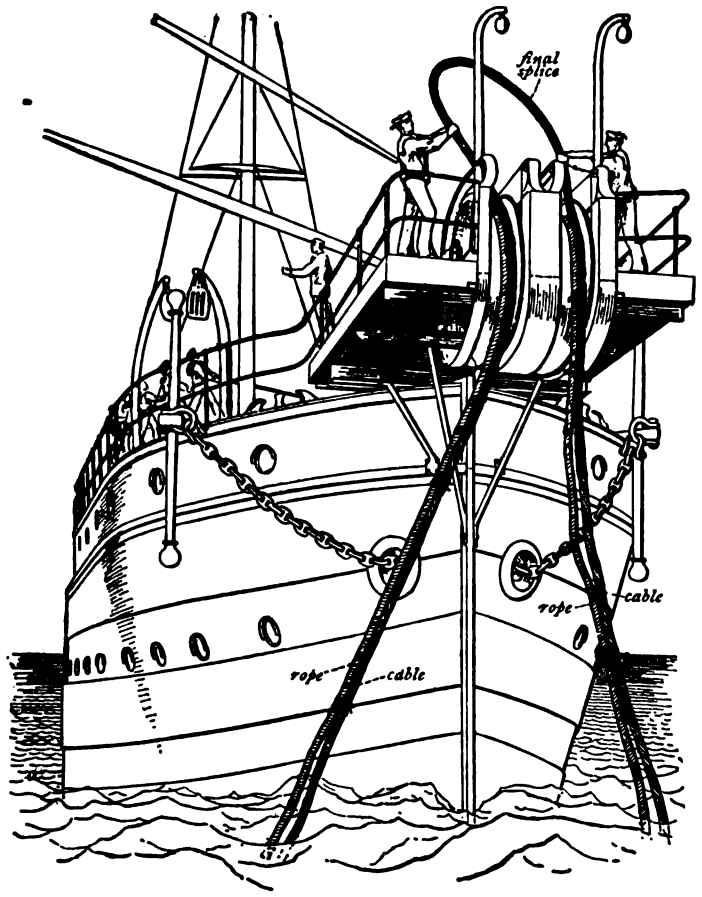

Fig. 71.—Clearing Final Splice over Bows.

to cable approach the bow sheaves the ropes are tied to the cables closer inboard, so that rope and cable on either side pass over the sheaves close together (*see* Fig. 71). This is done by men at the bows, one on each side, who continue to bind the rope and cable together with spun yarn at intervals of a few feet in this manner, while others carry the bight along the deck, keeping it open and clear of obstructions. When the bend of the bight reaches the bows it is lifted over clear of the sheaves, as shown in the illustration. The bight is then clear of the ship, and is still lowered by the ropes over the sheaves until it reaches the surface of the water. The men stationed at A A then cease to slacken out, and make fast, while a block of wood is placed at the bows under the two ropes, which are then cut through simultaneously with a sharp axe, the ends flying overboard, and the cable sinking to its resting place. The form of bow sheaves represented in Fig. 71 are provided with "whiskers" or cheeks between the sheaves for the purpose of preventing cable or grapnel rope jumping from one sheave to another when the strain comes on sideways.

We have now followed the movements and methods of practice on board a modern cable-repairing steamer from the moment of first dropping mark buoy to the moment of completing the repair and casting the final splice overboard. Incidentally some points of technical and general interest have been alluded to; but the ground to be covered in any study of this subject is very wide and full of interest, and all the more so because no two cable ships are exactly alike, and practice and methods differ in different companies. The author proposes now to discuss some of the most distinctive features of interest in different ships.

Erratum.—In paragraph 18, p. 557, *The Electrician*, September 23, Fig. 64 should have been stated to be from a photograph by Mr. W. J. Murphy, electrician on board the "Electra."

(To be continued.)

THE SUPPLY OF CURRENT BY METER.

BY T. P. WILMSHURST.

The method of charging for current adopted by the Yorkshire House-to-House Company, as published in *The Electrician* of the 30th ult., raises a question of some importance. A large number of supply companies have adopted the plan of allowing sliding scales of discounts to consumers, and of those who have no such published tables the majority find it expedient to make to their larger customers a substantial reduction of price, based on the quantity of current used.

The system in vogue is to allow a rebate to a consumer after a certain number of units have passed through his meter, irrespective of the number of lights that consumer may have. This, though undoubtedly the simplest method, is by no means an equitable one. Take the following instance. A customer, A, has 100 lamps which he uses an average of one hour per day throughout the year; B has 10 lights, and uses them 10 hours per day throughout the year. The number of units consumed by each is the same, and hence each receives the same rebate. B, however, is a far better customer to the supply company, for he helps to equalise their load curve, and only requires the use of one-tenth of the generating plant that A does,

To obtain a more even distribution of this load curve throughout the 24 hours is the fervent wish of central station officials. It was predicted that the more extended use of motors would bring about this happy result; but, unfortunately, it is found in practice that the hours of motor load overlap the hours of lighting load. One company, I believe, actually proposes to influence the lower parts of the curve by flooding the market with such apparatus as electric griddles, electric curling-tongs, and the like.

The simplest way out of this uneconomical state of affairs is, in my opinion, the application of an equitable system of rebates, which shall operate not simply on the numbers of units consumed per annum, but on the number of units consumed *per lamp* per annum. This will place the consumer with a small installation (but who wishes to use his light freely) on an equal footing with the consumer with a larger installation. Bearing these points in mind, the following table has been worked out for use at the Exeter supply station:—

Cost to a consumer of a 30-watt lamp in use for 365 days for the hours named in first column, at a sliding scale charge of—

7½d. per unit up to 12 units, 6½d. above 12 and not exceeding 16, 5½d. above 16 and not exceeding 20, and 4½d. above 20.

Hours of burning each day.	Units used per annum per 30-watt lamp.	No. of units at 7½d.	6½d.	5½d.	4½d.	Annual cost under sliding scale. £ s. d.	Average price paid per unit.	Price if at 7½d. £ s. d.
1	10·95	10·95	...	...	...	0 6 10½	7½d.	0 6 10½
2	21·9	12	4	4	1·9	0 12 3	6½d.	0 13 9
3	32·85	12	4	4	12·85	0 16 4½	6d.	1 0 7½
4	43·8	12	4	4	23·8	1 0 6	5½d.	1 7 6
5	54·75	12	4	4	34·75	1 4 6	5¼d.	1 14 4
6	65·7	12	4	4	45·7	1 8 7	5·2	2 1 0
7	76·65	12	4	4	56·65	1 12 8	5·1	2 7 9½
8	87·64	12	4	4	67·6	1 16 10	5·05	2 14 9½

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Nearly ready.*

DRUM ARMATURE WINDING, AND COMMUTATORS: In Theory and Practice. By F. M. WEYMOUTH. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRICITY AS A MOTIVE POWER. By A. T. SNELL. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

FULL CATALOGUE POST FREE ON APPLICATION.

All kinds of Technical and General Printing and Publishing undertaken by "THE ELECTRICIAN" *Company. Estimates free.*

STEEL-PLATE PORTRAITS

Of Willoughby Smith, W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, G.C.M.G.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz, Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), and Lord Rayleigh, F.R.S., have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

IRON LOSSES IN TRANSFORMERS.

While investigations on the magnetic properties of iron are being completed in the gradual but sure manner to which we alluded in our leading article last week, progress is being made in the kindred subject of the efficiency of transformers, and doubtful points are being cleared up. The alternate current transformer has come to be regarded, not so much as a piece of apparatus, but as natural production, a sort of animal whose habits are to be observed, or as a chemical compound which is to be analysed. In the early history of the transformer there was a difference of opinion as to how energy should be supplied to it. A change was made at the Grosvenor Gallery from series to parallel, a change of immense importance so far as both the generating and the distributing circuits and their regulation were concerned, but little or nothing was said about the transformer. Much ingenuity has been expended in designing economical stampings for the cores and in arrangement of coils to prevent magnetic leakage, but for one line on the design of transformers we read twenty on their efficiency. This may be accounted for to some extent by the fact that the subject is discussed from two very different points of view. The practical engineer is taunted by the low pressure continuous current man about his coal bill, and he vindicates his apparatus in his own way; the mathematician, on the other hand, finds that after making a few convenient assumptions about details on which he has little or no information, he can reel out yards of calculations, which, according to him, prove this, that, and the other. The practical man not understanding a word of it, cannot refute him, but sets to work to make experiments.

Digitized by Google

From experiments, however, whether carried out with the express intention of investigation, or, as in the case of what was once known as the Ferranti effect, arising out of practical working, almost all our knowledge of this intricate subject is due. But, owing to the difficulties of measurement and unsuspected causes, several paradoxes have arisen. The behaviour of these strange creatures, transformers, when harnessed in tandem on mains having appreciable capacity, attracted a good deal of attention about two years ago, and the discussion dropped only after elaborate experiments had been described. Losses in the iron of transformers have given rise to another riddle, propounded by Mr. MORDEY, and which seemed to be backed up by experiments made by Prof. AYRTON and others. The experiments were said to be "conclusive" and "absolutely and entirely correct," and it was related how the losses in a 2½-kilowatt transformer fell off on full load to three watts. The news was most welcome to alternate current men, and not least to the breeder of the particular transformer.

We have from the first refused to accept this result ourselves, chiefly because it was supported by experiment alone. No attempt at a scientific explanation was offered, but surmises about variations in the magnetising value of an ampere turn and other sundry guesses were made, some of which are recorded in our leading article on the subject on March 20th of last year. Hysteresis in these experiments, we there remarked, was treated as a residuum, and was, after all, nearly the same order as the errors of observation. It was, in fact, the petty cash of the balance-sheet. The mystery has now been dispelled by the use of Dr. SUMPNER'S method of testing transformers, fully described in these columns on July 1st, 1891. This is "the article in the technical press" to which reference is made in the Paper by Prof. AYRTON and Dr. SUMPNER, lately read before the British Association, or rather before an audience of about a dozen during luncheon-time, and which will be found elsewhere in our present issue. If it be worth while, the former misleading experiments might be repeated with the view of discovering the error, but the important fact remains that no occult property of iron, no inscrutable conduct of the ampere turns, and no incomprehensible trick of the transformer eager as it were for "collar-work," remains to be discovered to account for diminution of iron losses. These losses prove to be practically constant.

The myth of magnetic lag is dispelled one day, and the next sees the overthrow of a conjecture which was, while it lasted, a stumbling-block in the science of magnetism. Orthodox magnetic theory is thus confirmed, and now that confidence is restored, it is possible to calculate the efficiency of a transformer at any load when the open circuit losses and copper resistances are known. Another interesting result of this Paper is the proof afforded that the efficiency increases with the frequency, owing to a falling off in the open circuit losses. This conclusion is important from the point of view of the all-day efficiency of transformers. It is, however, to some extent counteracted by the effect of frequency on regulation. Prof. AYRTON and Mr. E. W. SMITH in another Paper read at Edinburgh showed that the lower the frequency, the better the regulation of the transformer for different loads. This result may be of as much importance as the mere alteration of efficiency. Slow frequencies have been proposed by Mr. CROMPTON, and more recently by Prof. FORBES. It may be remarked that that curious beast, the Hedgehog transformer, living in a drain pipe, and declining to behave like any other of its tribe, refused to submit to Dr. SUMPNER'S treatment, and exhibited curves, bristling with peculiarities, "sometimes of a curious character" which Prof. AYRTON and his colleague "have not yet had time to fully explain." That this investigation would be made, and that definite results would be forthcoming, was to be naturally expected after the publication of Dr. SUMPNER'S method of testing transformers. It was admittedly based, *mutatis mutandis*, on Dr. HOPKINSON'S method of testing dynamos, and attacking as it does the very quantity to be examined—the losses—is of considerable importance. No sooner was it published than we heard that it had been in use every day for months past for running transformers in a factory, but such a use of what is only after all a mode of coupling up the terminals, is very different to the careful research which has been conducted at the Central Institution with the assistance of Messrs. BAILLIE, BAYLEY, and CLIFT. So numerous, indeed, have been the experiments, that in forwarding the Paper for publication to different journals different curves were sent.

ON THE ELECTRICAL RESISTANCE OF PURE METALS, ALLOYS, AND NON-METALS AT THE BOILING-POINT OF OXYGEN.*

BY PROF. JAMES DEWAR, F.R.S., AND PROF. J. A. FLEMING, F.R.S.

Several observers have studied the behaviour of metals as regards electrical conductivity at low temperatures. In particular MM. Cailletet and Bouty (*Journ. de Physique*, July, 1885) have made observations of the resistance and resistance-change with temperature of various metals at—100°C. by the employment of liquid ethylene as a cooling agent. Wroblewski (*Comptes Rendus*, 1885, Vol. CI., p. 161) measured the electrical resistances of wires of electrolytic copper at various temperatures, 100°C., 20°C., 0°C. – 100°C., and gives also figures for the comparative resistance of the same wires at the critical point of nitrogen, the boiling-point of nitrogen, and the temperature of the solidification of nitrogen. The possession of means for producing very considerable quantities of liquid oxygen as well as liquid ethylene has placed at our disposal an opportunity of carrying out some investigations on the comparative electrical resistance of a number of pure metals, alloys, and non-metals at the low temperatures obtainable by the evaporation of liquid oxygen at ordinary barometric pressures and the ebullition of liquid oxygen under reduced pressures of about 25 or 30 millim. Since liquid oxygen, as already pointed out by one of us, is a very perfect insulating fluid, it is quite a simple matter, if once sufficient of the liquid gas is obtained, to measure the electrical resistance of a wire or small rod of the metal when immersed in liquid oxygen, and thus entirely at the same temperature as the evaporating liquid. A series of observations has accordingly been made by us on the specific electrical resistances of various metals, non-metals, and alloys over a range of temperature varying from + 100°C. to nearly – 200°C., and although these investigations are as yet incomplete, the observations already made seem to be of sufficient interest to render it worth while to place them on record.

A number of small resistance coils were prepared of wires of different metals and alloys in the following way. A thin rectangular sheet of mica about 5 centim. long and 1 or 2 centim. in width, had a number of nicks cut in the edges, and round this was wound loosely the wire whose resistance was to be determined. The ends of the wire were brought out through two holes in the mica and soldered to two stout copper terminal wires formed of high-conductivity copper wire well insulated with india-rubber. The ends of these terminal wires were bent over so as to dip into mercury cups. The small resistance-coil so formed could then be lowered into a test-tube full of the liquid gas or other fluid, by means of which the temperature of the wire was determined. The majority of the wires used had a length of 50 or 100 centim. and a diameter of ·003 of an inch (3 mils). The electrical resistance of these

* From the *Philosophical Magazine*.

Digitized by Google

small coils of wire was measured by a Wheatstone's bridge, kindly lent for the purpose by Messrs. Elliott Bros. The coils of this bridge were of platinum silver, and adjusted to read in B. A. units at 15°·5 Cent. The balance was determined by the use of a highly sensitive mirror-galvanometer, using the current from a single Helsen's dry cell. The experiments were carried out in the Royal Institution laboratories, in a room which remained approximately at about 20°C. during the whole time. A series of wires of pure metals was obtained, and also others of known alloys. Mr. J. S. Sellon and Mr. G. Matthey, of Messrs. Johnson and Matthey, of Hatton Garden, kindly provided for us carefully drawn wires of absolutely pure annealed platinum, pure gold (999·9 degrees of fineness), pure silver, aluminium, and tin. Also wires of alloys of platinum silver, iridium platinum, rhodium platinum, palladium silver, as well as wires of palladium, and of nickel. From the London Electric Wire Company was procured some electrolytic copper wire of the highest conductivity obtainable, and also from Messrs. Griffin and Co. some pure annealed iron wire. Other wires of commercial materials, *e.g.*, German silver, platinoid, tinned copper, tinned iron wire, and commercial tin, were also mounted. The mean diameter of all these wires was measured with the microscope-micrometer to the nearest ten-thousandth of an inch, and the length also carefully ascertained. The electrical resistance of each of these small resistance-coils was then taken at six or seven fixed temperatures, as follows:—

1. At about 100°C. when immersed in a paraffin-oil or glycerine bath heated with boiling water.

2. At about 20°C. when immersed in a paraffin or alcohol bath at normal temperatures.

3. At about 0°C. when in a paraffin oil or alcohol bath cooled by melting ice.

4. At − 80°C. when immersed in a bath of ether and solid carbonic acid.

5. At − 100°C. when immersed in a test-tube full of liquid ethylene boiling freely under atmospheric pressure.

6. At − 182°C. when immersed in a test-tube full of liquid oxygen boiling freely under atmospheric pressure.

7. At − 197°C. when immersed in a closed tube containing liquid oxygen boiling under a reduced pressure of about 25 or 30mm. of mercury.

In the case of the measurements in liquid oxygen and ethylene, the liquid gases were contained in double test-tubes holding about 200 cub. centim., which were kept filled up as fast as the liquid boiled away, in order that the resistance-coil might always be fully covered. Each measurement of resistance was repeated several times. We thus obtained a mean *observed resistance*, which is the mean resistance as measured on the bridge. This had then to be corrected by deducting the resistance of the leads up to and including that of the mercury cups in which the resistance coil terminals were dipped. This correction was found to be equal to 0·025 B. A. units at 20°C. The *corrected resistance* is the resistance of the coil after this deduction. A further correction was then applied for the temperature of the Bridge coils, which were used at a temperature of about 1°9·5 C., or 4°C. above the temperature at which they were correct; and also a reduction to true ohms, effected by the use of the factor 0·9866 recommended by the Board of Trade Electrical Committee (1 B. A. unit = 0·9866 true ohm).

If R is the *corrected resistance* in B. A. units of any coil of wire, the length of which is l centimetres and the mean diameter d mils (1 mil = 0·001 inch), and if ρ is the resistance of one cubic centimetre of the metal between opposed faces, in absolute electro-magnetic units, then it was found that ρ and R were related by the equation

$$\rho = 5000 \frac{d^2}{l} R;$$

in which the numerical constant embodies all the above corrections. In this reduction no correction has been applied for the charge in volume which the wire undergoes when raised or lowered in temperature. Hence the values of ρ thus obtained for various temperatures are not the true equi-volume specific resistances, or resistances across opposed faces of one true centimetre of the metal whatever its temperature; but the values of ρ are the relative resistances at the different temperatures of one cubic centimetre of the metal taken at the atmospheric temperature and allowed to shrink or expand with the temperature. They are, therefore, the relative specific resistances for constant mass and not for constant volume. These latter cannot be obtained until we know the true mean coefficient of cubical or linear expansion of the various metals and alloys between 0°C. and − 100°C. and − 200°C.; but in any case, even for the most expansible metal, the correction would probably not amount to one-half of a per cent., or to less than the error created in the measurement of the resistance by an uncertainty in the temperature to the extent of 1°C.

The following tables give these specific resistances for constant mass (ρ) at the various temperatures ($t°$) of the different pure metals, alloys, and impure metals employed. The mean value of the various results is given, and the temperature in degrees Centigrade placed over the number denoting the specific resistance in absolute electromagnetic units. If these specific resistances are plotted out in a series of curves (*see* Fig. 1*), taking the *absolute temperature* as abscissæ, we find that all the lines of resistance are more or less curved lines which tend downwards in such a way as to show that if prolonged beyond − 200°C. they would probably pass through or near the origin or absolute zero. These curves of resistance can be divided into three classes:—(i.) Those of metals such as iron, nickel, tin, and perhaps copper, which are concave upwards; (ii.) those of metals such as gold, platinum, and palladium, and probably silver, which are concave downwards towards the axis of temperature; and (iii.) those of metals such as aluminium, which are apparently nearly straight

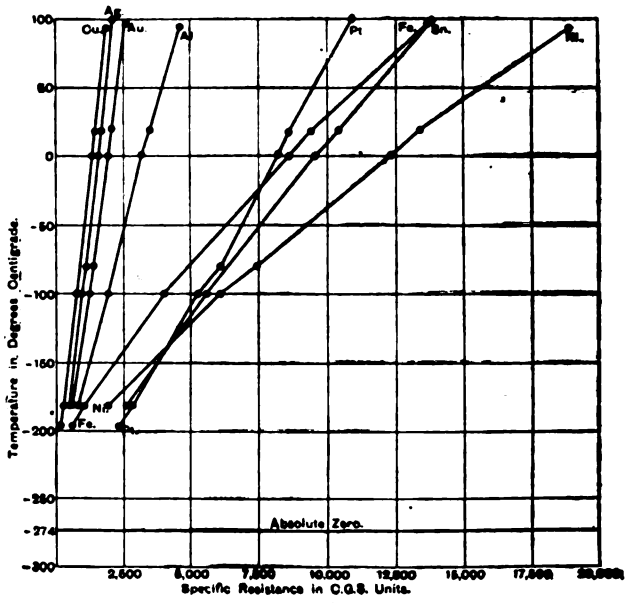

FIG. 1.

lines. In the case of a metal of the first class, such as iron, the resistance changes with the temperature in such a way that the rate of change of resistance with temperature *increases* as the temperature increases. In other words, the second differential of resistance with respect to temperature is *positive*. In the case of a metal of the second class, such as platinum, the second differential of resistance with temperature is *negative*—that is, as the temperature increases the rate of change of resistance with temperature *decreases*. This distinction between such metals as platinum and nickel, in respect of their variation of resistance with temperature, has been noted by Prof. Cargill G. Knott (*Proc.* Roy. Soc. Edin., Vol. XXXIII., 1888, p. 187), in a memoir on the Electrical Resistance of Nickel at High Temperatures. Prof. Knott's observations on the resistance of nickel were made between 0° and 300°C. Our own were between + 100° and − 200°C. Accordingly the distinction between these two

[* Pending the publication of curves by the authors we have taken the liberty of plotting out their observations. After the blocks were engraved we noticed that the authors refer to temperatures as abscissæ.—ED. *E.*]

metals, in this respect, extends over a very large range of temperature.

The most interesting fact which these experiments have brought out is the enormous decrease in specific resistance experienced by the *perfectly pure* metals when cooled to these low temperatures. Thus the electrical resistance of a given pure iron wire at −197°C. is only one twenty-third part of that which it is at + 100°C. In the case of pure copper the ratio of resistance is about one to eleven for the same change of temperature. The very smallest impurity greatly affects this decrease. In the case of some nickel wire supposed to be pure we found that the specific resistance at zero Centigrade was 13387 electromagnetic units, and that the specific resistance at − 182°C. was 6737. On repeating the measurement, however, with some absolutely pure nickel, obtained by Mr. Ludwig Mond's process of depositing the metal on glass by heating the gaseous compound of nickel and carbonic oxide, we found a very different result. In this

Digitized by Google

last case, although the specific resistance at zero Centigrade was not very different, viz., about 12000 units, the specific resistance at – 182°C. was only 1900, showing a far greater decrease. For the perfectly pure metals, therefore, it seems probable that as the temperature is lowered towards the absolute zero the specific electrical resistance decreases so that it either vanishes at the absolute zero or reaches a very small residual value. Clausius made the suggestion in 1858 (Pogg. *Ann.*, Vol. CIV., p. 650) that the electrical resistance of all pure metals is proportional to the absolute temperature. Owing to the marked curvature of the resistance temperature lines this statement is only very approximately true for a few metals, and not at all for others, but it yet remains not improbable that the electrical resistance of all pure metals would at the absolute zero be either null or exceedingly small.

In the course of our experiments we found that the trend of the curve of specific resistance drawn with absolute temperatures as abscissæ seemed to give a very good indication of the chemical purity of the metal. If that curve tended downward so as to indicate that if prolonged it would probably pass through the absolute zero, the metal was indicated as pure. If, however, as in the case of the palladium wire and the first nickel wire used, it did not so tend, then impurity was probably in some way present.

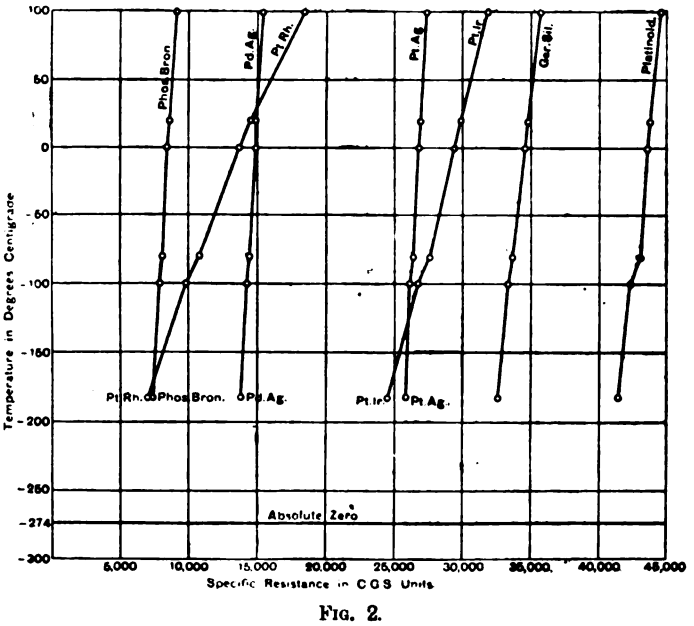

FIG. 2.

We next directed our attention to alloys, and Table II. is a table of the results obtained for them, treated in the same manner as regards temperature:—

On charting (*see* Fig. 2) the above figures for the alloys, it is found that the resistance-lines are very nearly straight lines with but little slope, not one-tenth that of the pure metals, when the constituent metals of the alloy are chemically very different. This is the case with the platinum silver, platinoid, and German silver alloys. When, however, the constituents of the alloy are chemically similar, as in the case of the platinum iridium and platinum rhodium alloys, the resistance-lines plotted in terms of the absolute temperature slope down at a much steeper angle, but never, as in the case of the pure metals, in such manner as to indicate that if prolonged they would pass through the absolute zero. In a similar manner the impure metals also behave. We have laid down on such a resistance-temperature diagram the lines representing the change of specific resistance with temperature for palladium not known to be pure, for nickel not pure, for commercial iron wire, for ordinary bismuth, for gold not pure, and other commercial metals, and found that the resistance-lines of these metals do not slope down at such an angle as to indicate that if prolonged they would pass through or near the origin or absolute zero. The lines for these impure metals are in position more or less like the lines for alloys formed of similar metals.

Another fact of considerable interest has been ascertained. We know that for temperatures above zero Centigrade, carbon behaves like an electrolyte as regards change of resistance with temperature, that is, its specific resistance *decreases* as temperature increases. Hence, it was a matter of importance to examine the behaviour of carbon as regards electric resistance when cooled to – 182° in liquid oxygen. For this purpose we employed the carbon filaments of incandescence lamps, taking the *treated* filaments of Edison-Swan lamps and the dense adamantine carbon employed in the Woodhouse and Rawson incandescence lamp. In both cases we found that when cooled to this low temperature the specific resistance of the carbon continuously *increased* (*see* Fig. 3) instead of decreasing, as do the metals. Table III. gives the specific resistance (ρ) in electromagnetic units of these carbons at various temperatures.

We have not yet completed the examination at similar low temperatures which we propose to make of the behaviour in regard to electrical resistance of such non-metals as selenium and sulphur, and such metals as arsenic and antimony, with marked chemical affinities with non-metals. Also the behaviour of such insulators as mica, glass, gutta-percha, india-rubber remains to be examined. It is known that the electrical resistance of these bodies decreases with rise of temperature. It is not improbable that we may find for such bodies a maximum electrical resistance at the lowest attainable tem-

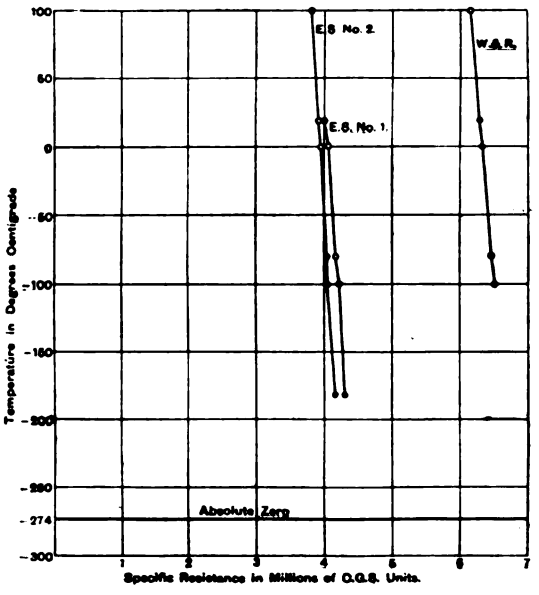

FIG. 3.

peratures, and that it may prove to be the case that pure non-metals approach a *maximum* specific electrical resistance and pure metals a *minimum* specific electrical resistance in proportion as the absolute zero of temperature is approached. In any case it is a matter of considerable interest to complete the examination of the change of conductivity with diminished temperature for all the metals in a state of the greatest chemical purity. MM. Cailletet and Bouty expressed the results of their experiments on the electrical resistance of metals between zero Centigrade and – 100°C. by giving the value of mean coefficient of resistance-change as follows:—If R_t is the electrical resistance of the metal at t°C., and R_0 its resistance at 0°C., then we may write

$$R = R_0(1 \pm \alpha t).$$

When t is in the neighbourhood of – 100°C., α has the following values, stated below, for the different metals. We give in one column the results of the experiments of MM. Cailletet and Bouty, and in the other coefficients for the same temperature range calculated from a part of our results in Table I.

From the values of the coefficients in Table IV. it is seen that nickel and iron have pre-eminence in respect of rate of fall of resistance with temperature. At ordinary temperatures pure iron has a specific electrical resistance of about seven times that of pure copper, and pure nickel has about ten times the resistance; but at the temperature of liquid oxygen boiling at

Digitized by Google

ordinary atmospheric pressure, the specific resistance of iron is only two-thirds of that of pure copper at the ordinary temperature, whilst that of nickel is only about twice as great as that of iron. It is a striking illustration of the effect of great cold on electrical conductivity to realise that at the temperature of boiling liquid oxygen pure iron conducts electricity better than the purest electrolytic copper does at ordinary temperatures. We hope before long to extend and complete the above investigation.

THE EFFICIENCY OF TRANSFORMERS AT DIFFERENT FREQUENCIES.*

BY PROF. W. E. AYRTON, F.R.S. AND W. E. SUMPNER, D.SC.

Some years ago Mr. Mordey published in the *Journal* of the Institution of Electrical Engineers the results of some experiments which appeared to show that, when a transformer of the Mordey type of construction was working at a given load, the waste of power was less at a frequency of 100 than at a higher or lower frequency. In 1888, to test this point, experiments were carried out at the Central Institution by Messrs. Lamb, Smith, and Woods, the power put into and taken out of a Mordey type of transformer being measured by the electrometer method, and it was for the purpose of these tests that there was constructed the large non-inductive resistance that was described by Mr. Mather and one of us before the Physical Society last year.

But, although this method is theoretically one of the best for ascertaining the power given by any current to any circuit, the percentage error in measuring the efficiency is, of course, the percentage error in measuring the power put into or taken out of the transformer. And as it is very difficult to avoid making errors of 1 or 2 per cent. with the electrometer method, it is almost impossible to be sure of changes of this magnitude in the efficiency produced by a variation in the frequency. Subsequently tests were made by others of the students, employing other methods for measuring the power, but it was not until one of us had devised the method that appeared this year in the technical press for measuring *directly* the losses in a transformer that we felt in a position to express an opinion regarding the actual effect produced by variation of frequency on the efficiency of a transformer.

Except under special circumstances, to be subsequently referred to, this method requires, for its employment, two transformers similar in type and output, and a third transformer, which may be of much smaller output, for supplying the energy lost in the coils of the two large transformers. The detailed working of the method will be understood on reference to Fig. 1. The fine wire coils of the two transformers A, B are connected in parallel through the high pressure switches *s*, *s*. The thick coil of A is connected directly with the mains, while the thick coil of B has one of its ends joined with one of the mains, and the other in series with a dynamometer D, a switch S_2, the current coil of the wattmeter W_1, the secondary of the subsidiary transformers C, and finally with the other main load. A switch S_1 is placed in one of the mains, as indicated in the figure, so that the current supplied directly from the mains can be switched off when desired. The primary of transformer C is connected with the mains through an adjustable resistance R_3 and a switch S_3. A wattmeter W_2 has its current coil joined up so as to be traversed by the current entering the parallel circuit formed by the primaries of A and B, and its pressure coil placed in series with the non-inductive resistance R_2 across the mains. The pressure coil of the other wattmeter W_1 is connected in series with the non-inductive resistance R_1 across the secondary of the auxiliary transformer C.

If the switches S_1, S_2, be closed the currents flowing are merely the magnetising currents required for the transformers A and B, and W_2 merely measure the open circuit losses. Unless the secondary of C be short circuited no current will flow through the thick coil of B, for the magnetising current is then supplied by the thin coil after transformation by A. If now switch S_3 be closed, so that the secondary of C supplies a potential difference of, say, 6 volts to the circuit forced by the thick coils of A and B, large currents will flow through the transformers. The potential difference between the terminals of A will be, of course, the voltage of the mains, for example 100, but the potential difference at the terminals of B will be either 106 volts or 94 volts, according as the six volts supplied by the secondary

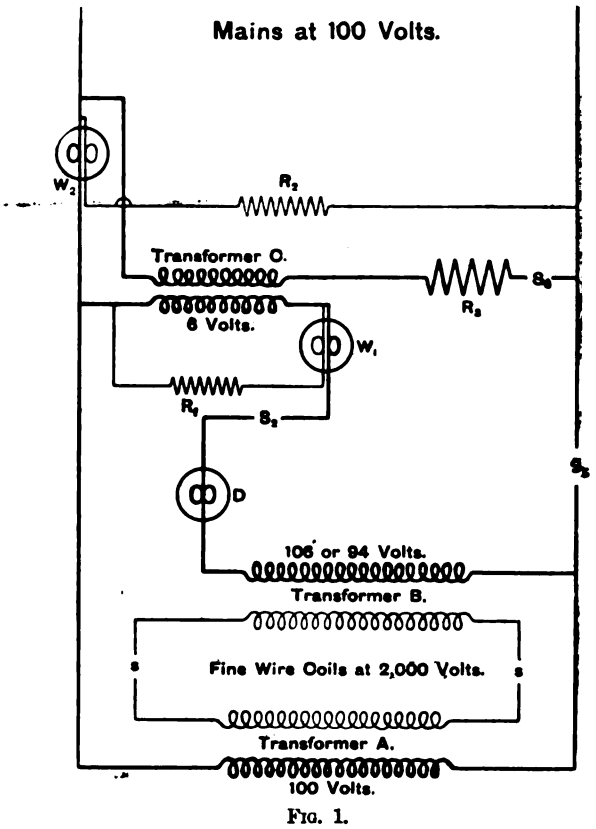

FIG. 1.

of C are in opposite phase, or in the same phase, as the 100 volts between the mains. (Indeed, if there were considerable magnetic leakage in the transformer C, or if R_3 were a highly inductive resistance, the potential difference of the six volts supplied by C would be out of phase with the voltage on the mains, and the potential difference at the terminals of B might be anything between 106 and 94 volts.) If there be a potential difference of 106 volts between the terminals of B, this transformer is being used as a step-up transformer, and A is converting downwards. If, however, there be only 96 volts between the terminals of B, it is A which is working as the step-up transformer, and B which is converting downwards. In the majority of the cases to be subsequently described the six volts supplied by C were sufficient to drive the full load currents through the transformers.

The load, W, we take as being measured by the product of the current indicated by D, and the potential difference supplied to the primary of the step-up transformer. If A is used for converting upwards, this load is simply 100 times the current in amperes, whereas if B is used as the step-up transformer the

* Paper read before the British Association in Section A, Edinburgh, August 5, 1892.

Digitized by Google

power returned to the mains by A is 100 times the current in amperes, and if to this we add the two power losses measured by W_1 and W_2, we obtain the power taken from the mains and supplied to the primary of B. If w be the load in watts supplied to the step-up transformer; if w_1 and w_2 be the watts at this load measures by W_1 and W_2 respectively; and if λ be at the same time the loss of power in the leads used in joining up the transformers, in the coils of the dynamometer D and in the current coil of W_1, the total loss in the two transformers is

$$w = w_1 + w_2 - \lambda,$$

and the efficiency of the double conversion is

$$\eta = 1 - \frac{w}{W}.$$

The advantage of this method of determining efficiency, as pointed out some years ago by Dr. Hopkinson in connection with a similar method of measuring the efficiency of dynamos and motors, is that a small error in determining either w or W will make practically no difference in the calculated value of η. For instance, as the value of η for *two* transformers is about 90 per cent., w is about one-tenth part of W, and it follows that an error of *10 per cent.* in estimating the ratio w/W only affects η to *1 per cent.*, and only affects the calculated efficiency of each transformer to *one-half per cent.*

It would have been more accurate had we placed the dynamometer D in circuit with the thick coil of A rather than with the thick coil of B, but the currents in the coils of A and B for closed magnetic circuit transformers differ to such a slight extent that either current may be approximately taken to represent the load without introducing any appreciable error in the determination of the efficiency.

The instruments used were of a rough character, and no special care was taken with them; for our object was rather to see how far measurements made by this method with common instruments could be relied upon, than to obtain the most accurate results possible.

D (*see* Fig. 1) is an ordinary Siemens dynamometer measuring up to 55 amperes for one revolution of the pointer when the thick coil is in circuit.

W_2 is a Ganz wattmeter, supplied, as usual, with two non-inductive resistances. In the following experiments its sensibility was such that one revolution of the pointer corresponds with about 1,200 watts.

W_1 is a Siemens dynamometer as made commercially but modified so as to form a wattmeter by connecting the mercury cups forming the ends of the movable coil with two separate terminals. This swinging coil was used, in series with a suitable non-inductive resistance R_2, as the pressure coil of the wattmeter, one of the fixed coils being traversed by the main current. When large currents were flowing through the thick coils of A and B a current of 8 or 10 amperes often passed through the *volt coil* of this wattmeter, and its attached resistance R_1; but although the power so wasted was quite appreciable, consideration of Fig. 1 will show that the reading of the wattmeter W_1 is not affected by it in the least, and that it thus does not enter into the calculation of the efficiency.

An ordinary Cardew voltmeter was used for the adjustment of the potential on the mains.

The transformers tested were:—

M_1, M_2. Two transformers of the Mordey type, each of output 4·5 kilowatts, converting from 2,000 volts to 100 volts (or 50 volts). They are numbered 1874 and 1872. We shall for brevity allude to them respectively as M_1 and M_2.

M_3. One transformer of the Mordey type of output 3 kilowatts, converting from 2,000 volts to 100 volts (or 50 volts). Its number is 1832, and in what follows it is alluded to as M_3.

M_4. One transformer of the Mordey type of output 1·5 kilowatts, converting from 100 volts to 100 volts. It has three coils each of the same number of turns, and occupying spaces proportional to the numbers 1, 1, and 2 respectively. The transformer was wound in this way for experimental purposes, but in other respects it does not differ in construction from the ordinary type made by the Brush Company in 1887. It is alluded to in the following experiments as M_4.

H. One Hedgehog transformer, made by Messrs. Swinburne and Co., of output 4 kilowatts, converting from 2,000 volts to 100 volts. It is referred to by the letter H.

A small transformer of change ratio 6 to 1 was occasionally used as the subsidiary transformer C. It was not, however, of any recognised commercial type and the magnitude of its efficiency does not enter into the tests.

The losses in the leads were carefully determined and confirmed by measurement made with different methods. The same leads and instruments were used in all the experiments. The first method of testing was to measure the resistances of the different coils and leads and calculate the losses at the currents used. These measurements were confirmed by passing steady currents of 30 and 40 amperes (measured by a standard d'Arsonval galvanometer used as an ammeter in shunt to a platinoid strip) through the leads and measuring with the aid of a standard voltmeter (a second d'Arsonval galvanometer used in series with known resistances) the power lost in the leads for these currents. The same experiment served to calibrate the dynamometer D. The wattmeters W_1 and W_2 had been previously calibrated by means of the same two standard instruments. The measurements were made when both the thin and the thick coils of the dynamometer D and the wattmeter W_1 were in circuit, since in the actual transformer tests it was occasionally found necessary to change these coils. The measurements of the losses in the instruments and leads were further confirmed by tests with *alternate currents* of the same frequencies as those used in the measurements; and it will be apparent that one of the advantages of the method of testing the efficiency of transformers which we have employed arises from the fact that the apparatus required for the efficiency measurements can be used for determining the losses in the leads, &c., *without any alteration of the connections*. For if the switch S_1 be open and switches S_2 and S_3 be closed and the primaries of the transformers A and B are short-circuited, the reading of the wattmeter W_1 will at once measure the losses occurring in the testing apparatus itself when any special current (measured by D) is passing though it.

The measurements made by these different methods were in quite satisfactory accordance with each other. With a current of 40 amperes the loss in the leads, when the thick coils of D and W_1 were used, was 55 watts. When the thin coil of D was substituted for the thick coil the extra loss at 40 amperes was 70 watts, and an equal increase in the loss was caused by using the thin coil of W_1 instead of the thick coil.

The losses occurring in the coils of the transformers can be measured independently of the other losses by simply leaving the switch S_1 open and taking the reading of W_1 for different alternating currents flowing through D. The two transformers A and B are so connected that a potential difference of a few volts will cause large currents to flow through the thick coils when the switches *s s* in the secondary circuit are closed. Of course the iron cores are magnetised slightly and a certain amount of energy is absorbed by hysteresis, but this is quite negligible compared with that lost in the copper. For, at most, the voltage corresponding with the induction of the core is only that needed for driving the currents through the resistance of the transformer coils. This is only about 1 per cent. of the ordinary voltage of the transformers and as the losses in the iron vary as the square of the induction density (more accurately as $B^{1\cdot6}$), the core losses are only $0\cdot01 \times 0\cdot01$, *i.e.*, 0·0001 of the normal losses occurring in the use of the transformer.

It thus becomes possible to investigate the very important matter of the variation of the core losses under different conditions of load. All that need be done is to determine:—

(1.) The total losses occurring in core, coils, and testing apparatus for different currents when S_1 is closed; and

(2.) The total losses in the coils and testing apparatus for the same currents when S_1 is open. The difference between the losses found for any particular current is the loss in the core for that particular load.

It was pointed out in the article in the technical press already referred to that the reading of W_2 practically gave the iron losses in the two transformers, and that W_1 gave the losses

Digitized by Google

caused by the heating effect of the currents in the coils, &c. The measurements made with closed circuit transformers have entirely confirmed this view.

Thus for the two 4½ kilowatt transformers of the Mordey type (M_1 and M_2), tested at 100 volts and a frequency of 160, the reading of W_2 gradually changed from 220 watts on open circuit to 230 watts at a load of 2,500 watts, and to 235 watts at a load of 5,000 watts, whereas the core losses as determined by the subtraction method were 220 watts on open circuit, 220 watts at a load of 2,500 watts, and 227 watts at a load of 5,000 watts, or practically the same as the watts as measured by W_2. In another test at a frequency of 150 the reading of W_2 changed from 210 watts on open circuit to 222 watts at a load of 4,000 watts, the iron losses, as calculated by the difference method, diminishing gradually from 210 watts on open circuit to 200 watts at a load of 4,000 watts.

In another test at the same frequency the reading of W_2 altered from 215 watts on open circuit to 210 watts at full load, while the iron losses were found exactly the same as the corresponding readings of W_2, up to a load of 3,000 watts; afterwards, however, the iron losses were slightly greater. In a test at a frequency of about 100 the reading of W_2 decreased from 260 watts to 250 watts as the load increased up to 4,000 watts, the iron losses being the same up to a load of 2,500 watts, and being slightly less afterwards and equal to 230 watts at a load of 4,000 watts. In a later test, at a frequency of 100, the reading of W_2 only changed from 285 watts to 290 watts from open circuit to a full load of 5,000 watts, while the iron losses diminished under the same circumstances from 285 watts to 275 watts.

In all these experiments numerous tests at intermediate loads were taken, and the general smoothness of the curves obtained by plotting the observations is such as to justify considerable confidence in the character of the results, the slight differences between the curves denoting the readings of W_2 and those representing the iron losses are sometimes in one direction and sometimes in the other, and are to be regarded as an indication of the extent of the experimental error to which the measurements are subject rather than as any certain evidence of alteration of the core losses with the load. In fact the experiments seem to show that, with closed circuit transformers at any rate, the core losses are practically constant at all loads. This conclusion is only what theory indicates, but it has frequently been doubted, as many published efficiency tests of transformers have indicated that the core losses diminish as the load increases.

This constancy of the iron losses is further evidenced by tests made with the other two Mordey transformers. Thus in testing the combination of the 4,000 watt Mordey (M_1) with the 3,000 watt Mordey (M_3) the iron loss at a frequency of 160 only altered from 185 watts at no load to 175 watts at a 4,200 watt load. In another test at a frequency of 200 the core losses changed from 170 watts at no load to 155 watts at a load of 4,200 watts. In a test of the 1,500 watt Mordey M_4 the iron losses at a frequency of 160 were found constant within 1 per cent. while the load changed from 0 to 3,000 watts or double full load.

When the open magnetic circuit transformer was used the measurements were not so satisfactory. Two or three reasons may be assigned for this. Owing to the large magnetising current the reading of the dynamometer D cannot be taken to indicate the current in the thick coil of A as well as that in the thick coil of B. Also owing to the great difference in the regulation of the Hedgehog transformer when converting up or down, the voltage on the transformer C had to be considerably greater than in the previous tests when the full load currents were flowing; and, consequently, while one of the transformers, A, B, is worked at the proper voltage, the other is worked at a voltage considerably different from 100. The curves obtained are sometimes of a curious character, and we have not yet had time to fully explain them. As we hope to repeat these tests, we prefer to postpone the publication of the results referring to the core losses of open circuit transformers. Our experiments, however, indicate that the iron losses do not alter by as much as 10 per cent. when the load is increased from 0 to full load.

Before summarising the results obtained it will be well to explain in detail the arithmetical working, by means of which the efficiency is obtained from a single set of measurements with the three instruments W_1, W_2, and D. When the two large Mordey transformers (M_1 and M_2) were being tested at a frequency of 107 it was observed that when the current as read by D was 44·8 amperes, W_1 indicated 310 watts, and W_2 indicated 290 watts. In this particular experiment M_1 was on the mains at 100 volts, and was used as a step-down transformer, the volts on the primary of M_2 being greater than 100 volts. While, therefore, $44{\cdot}8 \times 100$ watts were being returned to the mains by M_1, the thick coil of transformer M_2 was being supplied with $4{,}488 + 310 + 290$ watts. The load on the step-up transformer was thus 5,080 watts. The total loss in the two transformers is, however, less than 600 watts, since there is a considerable loss in the leads and dynamometers, &c. The loss in the leads at 44·8 amperes is 63 watts. The thin coil of W_1 was used in this particular test, so that an additional loss of 89 watts must be allowed for. No extra allowance has to be made for D, as the thick coil was used, and the loss in this coil is already taken into account in estimating the loss in the leads. The total loss in the testing apparatus for this current is therefore 152 watts, and the total loss in the transformers is thus $600 - 152 = 448$ watts. The joint efficiency at this load of 5,080 watts is therefore $1 - \frac{448}{5080} = 1 - {\cdot}0883 = 91{\cdot}18$ per cent. This number is the product of the efficiencies of the two

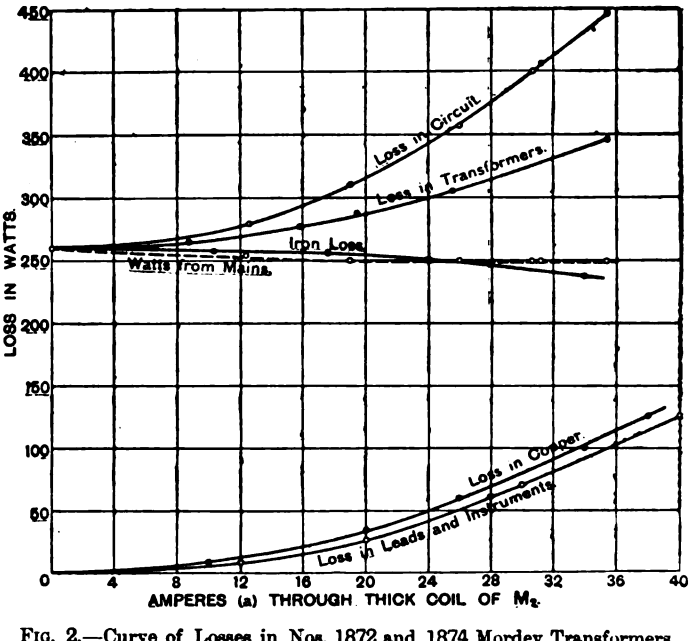

FIG. 2.—Curve of Losses in Nos. 1872 and 1874 Mordey Transformers. Primary Volts 100. Frequency 100. M_1 used as Step-down Transformer. M_2 used as Step-up Transformer. Load = 100a + Total Losses.

transformers, and, if these are assumed to be equal, the true efficiency is obtained by taking the square root of 0·9118, giving 95·5 per cent. Also if the copper losses at this current, determined by the method already described, be subtracted from the total loss of 448 watts, we obtain 275 watts as the iron losses at this load. This only differs by 15 watts from the actual reading of W_2.

This process has been gone through for each of the efficiency determinations made; but, in order to simplify the work, curves have been plotted denoting respectively the losses in the leads, in the transformer coils, the total losses in leads and transformers, the total losses in the transformers, the losses in the core, and the corresponding power supplied by the mains and measured by W_2.

The curves shown in Fig. 2 indicate a complete set of observations made on the two large Mordey transformers M_1 and M_2. As many as thirty such sets were taken in connection with different combinations of the transformers. Several of these had to be rejected from various causes. For instance, it was at first arranged, by means of a combination of switches, to make one wattmeter

Digitized by Google

do the work of the instruments W_1 and W_2, but after several measurements had been taken it was found that the alteration of the resistance of the circuit caused by the introduction of the wattmeter coil altered the currents flowing to a serious extent. The majority of the tests, however, confirmed each other in a very satisfactory manner. It is unnecessary to give the details of all the measurements, and we shall, therefore, merely give the numbers denoting the losses at different loads. These losses are interpolated from the curves drawn through the actually plotted points. The following table shows the results obtained from five sets of observations at various frequencies on the two large transformers M_1 and M_2.

Combined losses in two 4½ kilowatt transformers of the Mordey type.

—	Approximate frequency in periods per second.		
	100	120	160
Load in watts.	Loss in watts in the two transformers.		
1,000	292	270	229
2,000	305	280	241
3,000	335	305	275
4,000	375	345	320
4,500	400	...	...
5,000	425	...	...

From these numbers we obtain the following values for the efficiency of each of these two transformers :—

—	Approximate frequency in periods per second.		
	100	120	160
Load in watts.	Efficiency of each transformer.		
1,000	84·46	86·59	88·58
2,000	92·19	92·76	93·84
3,000	94·27	94·79	95·30
4,000	95·22	95·60	95·91
4,500	95·46	...	...
5,000	95·76	...	...

From these numbers it follows :—

1st. That the greater the frequency the higher the efficiency for any particular load.

2nd. That the greater the load the higher the efficiency for the same frequency.

Both these results follow, of course, from the fact that the iron losses are the same at all loads for a given frequency and diminish as the frequency increases. And they do not, for these particular transformers at any rate, confirm the results referred to at the commencement of this Paper that the efficiency is a maximum at the frequency of 100.

The open circuit losses expressed as percentages of full load are 3·2 per cent., 2·8 per cent., and 2·36 per cent. at frequencies of 100, 120 and 160 periods per second. If the iron losses be constant for all loads at a given frequency it can easily be proved that the efficiency of a transformer must be a maximum when the copper losses become equal to the iron losses. And calculation shows that for these two 4½ kilowatt transformers of the Mordey type, this equality will occur at a load of 7,200 watts at a frequency of 100, at a load of 5,500 watts at a frequency of 160, and at a load of 5,000 watts at a frequency of 200 periods per second, when the maximum efficiencies become 96 per cent., 96·1 per cent., and 96·3 per cent. respectively. There is, therefore, no great difference between the maximum efficiencies at different frequencies, but the higher the frequency the lower the load at which the maximum efficiency occurs.

The following table summarises the results obtained from the tests of the 3,000 watt (M_3) and the 4,500 watt (M_1) transformers of the Mordey type combined :—

—	Frequency in periods per second.		
	107	160	200
Load in watts.	Loss in watts in the two transformers.		
0	235	185	175
3,000	320	265	255
4,000	410	340	365

From these numbers we obtain the following values for the *joint* efficiencies of these two transformers :—

—	Frequency in periods per second.		
	107	160	200
Load in watts.	Joint efficiency of the two transformers.		
3,000	89·33	91·17	91·50
4,000	89·75	91·50	90·88

Now from the former tests we know the efficiency of M_1 at these loads and at two of the frequencies. We can thus obtain, by division, the efficiency of M_3, as follows :—

—	Frequency in periods per second.	
	107	160
Load in watts.	Efficiency of transformer M_3.	
3,000	94·76	95·66
4,000	94·25	95·41

The efficiency of the small 1,500 watt transformer (M_4) of the Mordey type was tested at a frequency of 150, and found to be 90·2 per cent., at a load of 1,500 watts, and higher at a larger output. The method used in testing this transformer is of some interest, arising from the fact that, as already stated, this transformer was for special experimental reasons so wound that it transformed from 100 volts to 100 volts. Now, when the change ratio of a transformer is unity, it is not necessary to employ another similar transformer when using our method of testing the losses directly, since the primary and secondary coils can be employed—one to take energy from the mains and the other to give back what is not lost in the transformation. Of course, an auxiliary transformer (C, Fig. 1) must be employed, but the two transformers, A and B in the figure, are replaced by the single unity change-ratio transformer M_4.

As the large transformers of the Mordey type are wound with two thick wire coils in addition to the fine wire one in order that the transformers may, if required, be used on the three-wire system, it is possible to measure the efficiency by the method just described without the employment of a second transformer. And tests that we made in this way confirmed those previously carried out.

But, as the fine wire coil of the transformer is not used, this method, although excellent for a transformer whose change ratio is unity, is not to be recommended for one which transforms from 50 or 100 to 2,000 volts. Indeed, it is obvious that if the test be made in the way just described the advantage of dispensing with the duplicate transformer is counterbalanced by the fact that the transformer tested can only be used at what is practically half load, and the copper losses are therefore proportionately greater than when the transformer is used in the ordinary way at full load. Employing, therefore, two similar transformers as well as a small auxiliary transformer as in Fig. 1, is much to be preferred.

A large number of tests were made by combining the Hedgehog transformer H_1 with M_1 and with M_3, and, although the results (as already mentioned) were not as satisfactory as when two Mordey type of transformer were employed, they were sufficiently accurate to show that neither at no load nor at full load is there any great difference apparently between the power wasted in a Hedgehog and in a Mordey type of

Digitized by Google

transformer of the same output. On this point, however, we shall say more when we have had more time to analyse the results we have already obtained with the Hedgehog transformer.

In conclusion, we wish to express our thanks to the Brush Company for so kindly lending us the two 4½ kilowatt transformers, and also our obligations to several students at the Central Institution, and more especially to Messrs. Baillie, Baylay and Clift, for their interest and energy in carrying out the experiments, and in reducing the results.

PROPAGATION OF THE CURRENT IN A CABLE CONTAINING DISTRIBUTED STATIC CAPACITY AND SELF-INDUCTION.*

BY FREDERICK BEDELL, PH.D., AND ALBERT C. CREHORE, PH.D.

The problem of the propagation of the electric current in a cable containing distributed static capacity was first discussed by Sir William Thomson, and afterwards by Mascart and Joubert,† Blakesley,‡ and others. The solution for the variation in the current and potential at different points of a conductor containing self-induction, as well as distributed capacity, has recently been given by the writers in the *American Journal of Science*,§ and some of the effects of the self-induction noted.

It is here intended to give a fuller treatment of the problem, and to discuss the nature of the wave propagation in such circuits.

Fig. 1 represents the longitudinal section of a cable, A being the conducting wire, and B B the insulating sheath which surrounds it. Let us suppose that this cable is submersed in

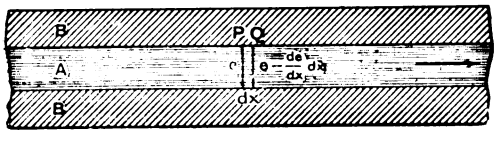

FIG. 1.—Longitudinal Section of Cable.

water, which forms the other conductor and plate of the condenser. If the capacity of a unit length be denoted by C, the capacity of the element P Q, whose length is dx, is C dx. Let R denote the resistance per unit length of the conductor, and Rdx the resistance of an element. Suppose a current i is flowing at P, in the positive direction, as indicated by the arrow. Let the potential of P at that instant be denoted by e. Since the current always flows from the higher to the lower potential, the potential of Q, the other end of the element, must be less than at P; and the potential, therefore, diminishes in the positive direction. This fall in potential between P and Q is denoted by $-\frac{de}{dx}dx$. By Ohm's law the current i, at any moment through the element P Q, equals the difference in potential divided by the resistance, and is, therefore,

$$i = -\frac{\frac{de}{dx}dx}{R\,dx} = -\frac{1}{R}\frac{de}{dx}. \quad . \quad . \quad . \quad . \quad . \quad (1)$$

If the current remained constant, having this value i all the time, the potential of the element and its charge would continually remain the same, and the flow of electricity across the section Q would be the same as that at P, since as much must flow out from as into the element, unless the charge of the element be changed. Now considering that the current does not remain constant, but changes every moment of time, the potential e, of the element and consequently its charge, must change with the time. When the charge changes, it means that more electricity is flowing into than out from the element, or *vice versa*, and consequently the flow of current across P is different from that across Q, by just such amount as the element gains or loses. The current at Q is then denoted by

$$i + \frac{di}{dx}dx.$$

Let the quantity flowing across the section P, in the time dt, be denoted by dQ, and that flowing across the section Q, by $dQ - dq$, where dq is the change in the charge of the element in the time dt. The quantity of electricity flowing across the section P is equal to the current flowing at P multiplied by the time, that is,

$$dQ = i\,dt, \text{ or } i = \frac{dQ}{dt}. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Similarly the flow across Q is the current flowing at Q multiplied by the time; that is,

$$dQ - dq = \left(i + \frac{di}{dx}dx\right)dt. \quad . \quad . \quad . \quad (3)$$

Subtracting (3) from (2), we obtain—

$$\frac{dq}{dt} = -\frac{di}{dx}dx. \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

This equation may be interpreted to mean that the rate of change of the charge on the element is equal to the difference of the currents flowing into the element and out from it. We might at once have written the equation from this consideration.

The charge of the element, as of any condenser, is equal to its capacity multiplied by its potential. The charge being denoted by q, the potential by e, and the capacity, as stated above, by C dx, we have,

$$q = C\,e\,dx. \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

The rate of change of the charge with the time is, by differentiation,

$$\frac{dq}{dt} = C\frac{de}{dt}dx. \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Equating this result to equation (4), we have

$$-\frac{di}{dx} = C\frac{de}{dt}. \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Equations (1) and (7) are the differential equations which are sufficient to determine the problem of the propagation of the current in a cable with distributed capacity when the impressed E.M.F. of the source is known. The solutions of these equations may be obtained for the most general case, although the arbitrary constants of integration can only be determined in certain particular cases where the impressed E.M.F. is known. When the impressed E.M.F. is harmonic and equal to $e = E \sin \omega t$, the arbitrary constants may be found.

These two differential equations may be expressed as a single equation by differentiating (1), with regard to x, and equating to (7); thus,

$$\frac{di}{dx} = -\frac{1}{R}\frac{d^2e}{dx^2}, \quad \text{and, therefore,}$$

$$\frac{d^2e}{dx^2} = C\,R\frac{de}{dt}. \quad . \quad . \quad . \quad . \quad . \quad (8\frac{1}{2})$$

In the foregoing discussion no account has been taken of the self-induction of the circuit, but it necessarily has a certain effect upon the flow of the current, which we will now consider. The effect of self-induction must be felt as a back E.M.F. opposing the current and depending upon its rate of change. We shall assume that this back E.M.F. per unit length of the conductor is equal to the rate of change of the current, multiplied by a constant; that is, it is equal to $L\frac{di}{dt}$. In some cases this assumption may approximately represent the true effect of self-induction, and it is thought that this particular assumption may show the nature of the effect of self-induction even in cases where this assumption is not justifiable. Instead of leaving equation (1) as it stands, therefore, without taking into account the effect of the back E.M.F. of self-induction, we may introduce this effect into the

Digitized by Google

equation by subtracting from the difference of potential between P and Q, viz, $\frac{de}{dx}$, the internal E.M.F. of self-induction, $L\frac{di}{dt}dx$, and so may write,* still in accordance with Ohm's Law,

$$i=\frac{\left(\frac{de}{dx}dx-L\frac{di}{dt}dx\right)}{R\,dx}=-\frac{1}{R}\frac{de}{dx}+\frac{L}{R}\frac{di}{dt}. \quad . \quad (8)$$

The relation in equation (7) is not changed by the consideration of the self-induction, and these two equations (7) and (8) are sufficient to determine the problem of the flow of current, taking into account both the capacity and the self-induction. These equations, now containing four variables, may be expressed as two differential equations containing three variables by eliminating first i and then e. After transposing and arranging, we may write (7) and (8).

$$C\frac{de}{dt}+\frac{di}{dx}=0. \quad . \quad . \quad . \quad . \quad . \quad (9)$$

$$\frac{de}{dx}-L\frac{di}{dt}+Ri=0 \quad . \quad . \quad . \quad . \quad . \quad (10)$$

Operating upon (9) by $\frac{d}{dt}$, that is differentiating with respect to t, we obtain

$$C\frac{d^2e}{dt^2}+\frac{d\left(\frac{di}{dx}\right)}{dt}=0. \quad . \quad . \quad . \quad . \quad (11)$$

Operating upon (10) by $\frac{1}{L}\frac{d}{dx}$, we find,

$$\frac{1}{L}\frac{d^2e}{dx^2}-\frac{d\left(\frac{di}{dt}\right)}{dx}+\frac{R}{L}\frac{di}{dx}=0. \quad . \quad . \quad . \quad (12)$$

Adding (11) and (12), we have

$$C\frac{d^2e}{dt^2}+\frac{1}{L}\frac{d^2e}{dx^2}+\frac{R}{L}\frac{di}{dx}=0. \quad . \quad . \quad . \quad (13)$$

Substituting here the value of $\frac{di}{dx}$ in (9), namely, $-C\frac{de}{dt}$, we eliminate i and finally have for the differential equation of the potential

$$\frac{d^2e}{dx^2}+LC\frac{d^2e}{dt^2}-RC\frac{de}{dt}=0. \quad . \quad . \quad . \quad (14)$$

To eliminate e from (9) and (10), operate upon (9) by $\frac{d}{dx}$, and upon (10) by $C\frac{d}{dt}$, and we have

$$C\frac{d\left(\frac{de}{dt}\right)}{dx}+\frac{d^2i}{dx^2}+\frac{d^2i}{dx^2}=0, \quad . \quad . \quad (15)$$

and

$$C\frac{d\left(\frac{de}{dx}\right)}{dt}-LC\frac{d^2i}{dt^2}+RC\frac{di}{dt}=0. \quad . \quad . \quad . \quad (16)$$

Subtracting (16) from (15), we have the differential equation for current.

$$\frac{d^2i}{dx^2}+LC\frac{d^2i}{dt^2}-RC\frac{di}{dt}=0. \quad . \quad . \quad . \quad (17)$$

It is evident from the similarity of the equations (14 and 17) that the integral current equation will be the same as the integral potential equation, except for the arbitrary constants that enter in integration. The general solutions of these equations are:—

$$e=\sum_{h,k}hk\epsilon^{\frac{R(t-ckx)}{ck^2+L}};$$

$$i=\sum h\epsilon^{\frac{R(t-ckx)}{ck^2+L}}.$$

where ϵ is the base of the Naperian system of logarithms, and h and k are arbitrary constants. The equations may be verified by differentiation, and found to satisfy the differential equations (14 and 17), of which they are the complete integrals. If we know how the current or potential varies with the time at any one point of the cable, the arbitrary constants h and k can be determined, and we have the complete solution of the problem, and are able to tell the potential or current at every point of the cable at any time.

If the potential is caused to vary harmonically at any point of the cable, and at that point $e=E\sin\omega t$, the constants of the general solution may be determined. When the variation is harmonic, it will be found that the constants in the general solution, which is of the exponential form, have imaginary values. The exponential solution may then be transposed into a sine-function where the constants have real values. Instead of performing this transformation from the exponential to the sine form, which is somewhat laborious, we may immediately assume the solution to be of the sine form, or

$$e=h\epsilon^{rt+px}\sin(\beta t+\alpha x),$$

where x is the distance from the source of E.M.F., and where α, β, h, r, and p are arbitrary constants to be determined so as to satisfy the differential equation (14). We see that the constant r must be zero, for, when $x=0$, the E.M.F. at the origin is $E\sin\omega t$ by our supposition. Therefore, $h=E$, and $\beta=\omega$; and only the constants p and α remain to be determined. The E.M.F. is

$$e=E\epsilon^{px}\sin(\omega t+\alpha x). \quad . \quad . \quad . \quad . \quad (18)$$

By differentiation we obtain

$$\frac{d^2e}{dx^2}=(p^2-\alpha^2)\epsilon^{px}\sin(\omega t+\alpha x)+2p\alpha\,\epsilon^{px}\cos(\omega t+\alpha x)$$

$$CL\frac{d^2e}{dx^2}=-CL\omega^2\left[\epsilon^{px}\sin(\omega t+\alpha x)\right]$$

$$-CR\frac{de}{dt}=-CR\omega\left[\epsilon^{px}\cos(\omega t+\alpha x)\right]$$

Equating the coefficients of the sine and cosine, separately, to zero, we obtain the simultaneous equations

$$p^2-\alpha^2-CL\omega^2=0, \quad \text{and}$$
$$2p\alpha-CR\omega=0.$$

Solving these equations for p and α, we find that

$$p=\pm\sqrt{\frac{C\omega}{2}}\sqrt{(R^2+L^2\omega^2)^{\frac{1}{2}}-L\omega}, \quad . \quad (19)$$

$$\alpha=\pm\sqrt{\frac{C\omega}{2}}\sqrt{(R^2+L^2\omega^2)^{\frac{1}{2}}+L\omega}. \quad . \quad (20)$$

Substituting in (18) these values of p and α, and writing Im. for the impedance $(R^2+L^2\omega^2)^{\frac{1}{2}}$, we have as the expression for the potential at any time and at any point of the conductor a distance x from an harmonic source of E.M.F.,

$$e=E\epsilon^{\pm\left[\sqrt{\frac{C\omega}{2}}\sqrt{Im-L\omega}\right]x}$$
$$\sin\left\{\omega t\pm\left[\sqrt{\frac{C\omega}{2}}\sqrt{Im+L\omega}\right]x\right\}. \quad . \quad (21)$$

The discussion of this equation will be given after the corresponding equation for current is obtained.

To Obtain the Current.

The current may be obtained from the potential equation by means of the relation $C\frac{de}{dt}=-\frac{di}{dx}$. [See equation (7).] Differentiating (18) with respect to t, and multiplying by C, we obtain

$$C\frac{de}{dt}=CE\omega\epsilon^{px}\cos(\omega t+\alpha x)=-\frac{di}{dx}.$$

Integrating this result with respect to x, we get

$$i=\frac{-CE\omega\epsilon^{px}}{p^2+\alpha^2}\left\{p\cos(\omega t+\alpha x)+\alpha\sin(\omega t+\alpha x)\right\}.$$

* [Several of the signs in equations (8) to (18) appear to us to be wrong in the manuscript supplied by the authors from the Cornell University, Ithaca, U.S.A. As, however, the changes which we think necessary only in the end alter the sign of R in (18) the equations (19) and (20) are unaltered, and the practical conclusions which follow are correct.—Ed. *E.*]

Digitized by Google

By a trigonometic transformation this may be written in terms of the sine only, and we finally obtain

$$i = -E\sqrt{\frac{C\omega}{I m}}\,\epsilon^{px}\sin\left\{\omega t + \alpha x + \tan^{-1}\sqrt{\frac{I m - L\omega}{I m + L\omega}}\right\} \quad (22)$$

Here p and α represent the expressions (19) and (20).

This equation gives the value of the current at any time and at any point of a conductor containing distributed capacity and self-induction when subjected to an harmonic source of E.M.F. The discussion of this equation and the potential equation will next be taken up.

In order to ascertain the physical effects of distributed self-induction and capacity in a circuit, we will first discuss the analytical results just obtained as applied to a circuit in which the self-induction is neglected; and then, after investigating the nature of the wave propagation, the wave length rate of propagation and rate of decay, we will consider circuits containing distributed capacity and self-induction, noting the changes caused by the introduction of the self-induction.

(To be continued.)

AUSTRALASIAN TELEGRAPH RATES.

A deputation representing the banking, shipping, mining, and general commercial interests connected with the trade between Great Britain and Queensland, waited on Wednesday at the offices of Messrs. Gray, Dawes, and Co., No. 13, Austinfriars, on the Hon. W. Horatio Wilson with reference to the rates at present charged for telegrams to and from Queensland. The Hon. W. Hemmant (of the firm of Messrs. Stewart and Hemmant) occupied the chair; and the following firms, companies, and gentlemen formed the deputation or expressed sympathy with its object, and desired their names placed on the attendance roll:—Aplin, Brown, and Co. (W. Villiers Brown, M.L.A.), R. L. Armour and Co. (Limited), Chas. F. Moberly Bell (*The Times*), John Bell (F. Green and Co., and Orient Steam Navigation Company), Brodziak and Rodgers, Brand, Dryborough and Burns, Henry Brandon, Bank of Queensland (Limited), Bank of Australasia (P. Selby), Brabant and Co., W. Balchin, Chas. E. Bright, C.M.G., Philip Burns and Co. (Limited) (D. Patience), John Blyth and Co., D. L. Brown and Co., R. Clayton and Co. (Reginald Clayton), Central Market Cold Air Stores (Limited) (A. Towers), De Lissa, Sons, and Co. (S. De Lissa), Dalgety and Co. (Limited), Oscar De Satgé, Captain Elmslie (Elmslie and Co.), A. Forbes and Co. (Arthur Forbes), H. S. Fitter and Sons, Finney, Isles, and Co., M. B. Foster and Sons, Gray, Dawes and Co. (E. S. Dawes), Gordon and Gotch, Robert Gray, Antony Gibbs and Sons, Sir Arthur Hodgson, K.C.M.G., Hollis, Hopkins, and Co. (Limited) (T. Hollis Hopkins), S. Hoffnung and Co., G. T. Hayzen, Jeremiah Lyon and Co., B. S. Lloyd and Co., McNeil, Duncan and Co. (Sinclair MacLeay), McLean, Bros., and Rigg (Limited) (F. Chapman), James McEwan and Co (Limited), John McDonald, Parbury, Lamb, and Co., Queensland National Bank (Limited), Queensland Smelting Company (Limited), Alfred Romilly, Charles C. Rawson, Rylands and Sons (Limited), Stewart and Hemmant (Hon. W. Hemmant), Sir Thomas Sutherland, M.P., K.C.M.G. (Peninsular and Oriental Company), C. G. Tindal (Australian Meat Company), "Ramornie," Union Mortgage and Agency Company of Australia (Limited), W. Weddel and Co. (W. Weddel), Watson, Ferguson, and Co. (James Gray), Blundell H. Weld.

The CHAIRMAN, in opening the proceedings, said: I presume you are all acquainted with the object of our meeting to-day. It is to take advantage of the presence in London of a member of the Queensland Government to urge upon him the desirability of his Government joining with the other Australian Colonies in the guarantee to the Cable Companies to protect them against loss through the reduction of the tariff. A statement has been prepared by the hon. secretary (Mr. J. Troubridge Critchell) which will show exactly what our object is, and with your permission I will read it. It is as follows: On May 1, 1891, the agreement made between the colonies of New South Wales, Victoria, South Australia, Western Australia, and Tasmania, and the Eastern Extension Telegraph Company come into force; under the guarantee of the colonies named to bear 50 per cent. of any loss which might occur for the period of one year, the loss to be apportioned on a population basis, the rates for ordinary cablegrams between Great Britain and the guaranteeing colonies were lowered to from 4s. to 4s. 8d. a word. The colonies of Queensland and New Zealand declined to join the agreement, and the rates—9s. 5d. and 10s. 4d. respectively—remained the same as before. The tentative period of one year having expired, it was found that a loss (comparing the receipts at the reduced rates with the earnings of the Australasian cable traffic at the time the agreement was made) had been incurred of £55,040. This deficiency was divided between the signing colonies and the cable companies according to the arrangement stated above. It is now proposed by New South Wales and the other guaranteeing colonies to raise the ordinary tariff to 4s. 9d. a word, which increase will, so it is calculated, reduce the loss for the next year's operations to about £17,000, and therefore the colonies may anticipate being called upon to contribute, say, £8,000 as their share. It is considered probable that a new agreement on these lines will come into force about November 1st in this year. New Zealand will be a party to the guarantee. Queensland, therefore, is now the only member of the Australasian group standing out of the guarantee. The presence in London of the Hon. W. Horatio Wilson has induced the mercantile community interested in the trade between Great Britain and Queensland to form a deputation to wait upon him and respectfully urge the desirability of his Government joining the guarantee, so that the somewhat harsh disability under which persons who have to cable to Queensland, and from Queensland to Great Britain, are now placed may be removed. When Mr. Wilson was approached and asked if he would receive such a deputation he consented, and on its being pointed out to him that it would almost be an impossibility for a representative body of City men to wait upon him at the Westminster Palace Hotel he waived the point, and agreed to meet the deputation at the offices of Messrs. Gray, Dawes, and Co., kindly granted by that firm for the purposes of the meeting. It may, perhaps, be well to point out, in the most definite terms, before stating the case, that the initiation of this movement is due to the concerted action of the firms and gentlemen whose names appear on this paper; neither the cable companies nor any other interested institutions or persons have had anything to do with the formation of the deputation, directly or indirectly. The deputation respectfully approaching the Queensland Government desires to represent the hardship borne by firms and persons in Great Britain who use the cable to the colony, of having to pay 9s. 5d. a word when the tariff to the other Australian Colonies is now but a little over 4s., and will be under the fresh agreement 4s. 9d. The deputation points out that according to estimates that have been authoritatively published the loss to the guaranteeing colonies for the ensuing year (assuming that the colonies and the cable companies renew the agreement) will be about £8,000. Were Queensland to join with the other colonies her share of the loss would be about £800, and the increase of business likely to follow would probably still further reduce this sum. Under the operations of the first tentative year Queensland's share of loss, had she been one of the guaranteeing colonies, would have been about £5,000; but now that a more reasonable tariff has been proposed, and the probable loss shown to be but this small amount (a loss which the deputation contends would be made up over and over again to the community), it appears that the financial objections to the colony's joining in the agreement practically fall to the ground. The cheapening of postal and telegraphic facilities is rightly judged to be an important part of the world's progress, especially in the case of the scattered States of the British Empire. It is within the knowledge of members of this deputation that the (comparatively) high cable tariff of Queensland has affected her commercial and mining relations with the United Kingdom prejudicially. A considerable saving would accrue to the colony were she to join the guarantee, owing to the reduction on Government messages, which are now under the ordinary 9s. 5d. a word tariff; as a member of the guaranteeing colonies she would send her Government messages for about 3s. 10d. a word. The amount so saved to the taxpayers of Queensland might possibly be a considerable proportion of the £800. This deputation, representing the landed, commercial, shipping, and mining interest concerned in Great Britain, Queensland interchange, respectfully ask the Queensland Government to consider whether they cannot recede from their present position of refusal to join the cable guarantee. As the agreement is made from year to year, Queensland would, if she were to join, only bind herself for one year, and could retire at the expiration of the term if it were considered advisable to do so. The deputation have no desire to enter upon considerations of public policy; they only wish to do what has never been done before—give expression to the views of the Anglo-Queensland commercial community as to this important matter, solely from a business standpoint. They desire to indicate their earnest hope that the Government will see their way to effect this reform in the intercommunication of the communities of Great Britain and the colony of Queensland. Mr. Oscar De Satgé, who intended to be present, has telegraphed that, owing to illness, he is unable to attend; and Mr. Bright, of Messrs. Bright Bros., has written to say that, owing to a previous engagement, he cannot be with us. I do not know that I can add anything to what has been stated. We all feel that it is somewhat of an anomaly that one colony should stand out from all the others, and I feel sure from what I see of telegraphing that the Government would not be a penny out of pocket by joining in the agreement. The saving they would effect would quite make up the share of the loss which the Queensland Government would have to bear on the population basis. We know that the finances of the colony are not quite what could be wished, and I should be extremely reluctant to urge the Government to depart from the lines of economy which we all see that they are now engaged on. This, however, is a very trifling matter, and they would make up by the saving they would effect on the Government messages the amount they would have to pay under the guarantee.

Mr. E. S. DAWES, having expressed satisfaction at seeing such an influential gathering, said: The large attendance shows how very warm an interest is being taken in cheapening the communications between Queensland and the United Kingdom. Of the value of such increased communication I am sure we must all be fully aware. Not only are we hampered in our commercial transactions by the dear tariff—for none of us care to spend 10s. 1d. a word if we can help it—but it has a tendency to put Queensland into the background, a position that I myself, having a very warm regard for the colony, very strongly resent. If the effect of this really very influential meeting should be to induce the Government to give a trial to the proposal that is now made, I am sure we shall all be very grateful.

The Hon. SECRETARY announced that Mr. Moberly Bell, of *The Times*, was unable to be present, but had forwarded a letter expressing his complete sympathy with the object of the deputation, and stating that that journal might feel compelled to discontinue giving the same prominence to Queensland politics as they gave to those of other Australian colonies unless the Queensland Government could see its way to securing the same tariff rates as prevailed from and to Victoria, New South Wales, and the rest of Australasia.

Digitized by Google

Mr. W. VILLIERS BROWN said: I can scarcely claim to be one of the mercantile community of London; but I have a great many communications with London as a Queensland merchant, and I am quite alive to the importance of the concession we are about to ask the Queensland Government to make. It is very well known to me, and to those present, no doubt, that for a considerable time past the Queensland people have been sending their messages through the other colonies. That is not a desirable thing to encourage—in fact, it is scarcely what we should like to see. I think the amount involved is, according to the figures which have been put before us—which appear to have been very carefully prepared—so small that the Government can scarcely hesitate any longer to join in the agreement. I may, however, say that I do not know that it has been a matter of economy altogether with the Queensland Government. I have no doubt that they have had some good reasons for refraining from taking part in the agreement hitherto, but that is a matter on which we have no information, and are not likely to receive any, for although we have a member of the Government present, he would not be likely to say anything on such a subject. I think it likely, however, that those reasons may no longer exist. The main point for us is, I think, to convince Mr. Wilson of the necessity of this concession, and to get him to go heartily into the subject and make representations to his Government regarding it. From what I know of matters in Queensland I feel sure that if Mr. Wilson takes up the subject heartily and puts it before his Government our prayer will be entertained. Speaking personally, I shall be very glad on my return to Queensland if I can strengthen Mr. Wilson's hands, either as a member of the Legislature or as a Queensland merchant.

Mr. JOHN McDONALD: The memorandum which has been read to us has set the whole business before us so clearly that I cannot add anything to it which would make the matter more clear. As, however, I send a good many cablegrams to Queensland, I may say that I think it would pay those in this country who send cablegrams to Queensland to take upon themselves to provide the £800 in question—that is to say, if the Government of the colony cannot do so without spending more money than they can afford. I believe it costs the people who send telegrams from this country more than the £800. It is true that the messages are not sent direct through the cable companies; they go to Reuter s, but that Company charge an extra price for sending the messages round by Melbourne, and I feel sure that that extra sum would amount to more than £8.0. There would be a gain to the people of this country—for a saving is a gain—and they would save that extra cost if the Government of Queensland would consent to join the other colonies; but I look at it that the expansion of trade through the reduction in the cost of cable messages would be of much greater advantage to the Colony of Queensland, and that a great many times £800 would be gained by them. In contrast to the action of the Queensland Government with respect to cable messages I would point out what they did with regard to the establishment of a parcels post. Last year when Mr. Wilson visited this country a deputation waited upon him respecting this matter, and the result was that a parcels post was established. I trust, also, that on this occasion the Government will see their way to grant our wish. I may mention thet Mr. Wilson deserves all the credit, or nearly so, for initiating the parcels post and carrying it through. It had to be brought into the Lower House, but he prepared a measure and carried it through the Upper House.

The Hon. W. H. WILSON: Mr. Chairman and gentlemen, I am sure I have been very pleased indeed to receive this deputation, because the matter which has been brought under my notice is one of very great importance; and certainly, from the point of view of the deputation, and the way in which it has been placed before you, it seems to me that a very strong case indeed has been made out. I feel very great sympathy for the wishes of the deputation, and I trust that my Government—I am quite sure of it—when they consider the question, will give great weight to the views of such a large and influential deputation as that which I have had the honour to receive to-day. The question resolves itself into a different form, I think, now to what it has hitherto done. The loss that is likely to accrue is so small that it is a mere bagatelle. Under those circumstances I hope and believe that the Government will now be enabled to give it a far more favourable consideration than they could possibly do under other circumstances. I shall be pleased to communicate to my colleagues the views of the deputation, as expressed in the circular which has been read, and I will also do everything that I can to further the object of the deputation.

Mr. WEDDEL, in proposing a vote of thanks to Mr. Wilson, said: Everyone agrees that any country which is to remain in the foreground of nations must have the cheapest postage and the cheapest cable communication that is to be obtained; and any country or colony that is not in that position is bound to recede into the background. Excepting Queensland all the Australian colonies—and New Zealand now—have agreed to come into this federation; but after the strong arguments which have been put forward to-day I have very little doubt, from what Mr. Wilson has said, that he will use all his influence to prevent Queensland from being in any way put into the background. I am sure that we are also greatly indebted to Messrs. Gray, Dawes and Co. for their kindness in giving us the use of this room.

Mr. ROBERT GRAY (Queensland), in seconding the resolution, said: I quite agree with Mr. Wilson that the question which has brought us together has now assumed a different complexion from what it had when the Government of Queensland felt unable to join in the agreement. The deficit now appears as if it will be much smaller, and I trust that the Queensland Government will see their way to meeting the views of the deputation. I am sure that all present agree in thanking Mr. Dawes. That gentleman's firm is well known in Queensland as most enterprising and public spirited.

The resolution was carried unanimously, and was briefly acknowledged by the Hon. W. H. Wilson and Mr. Dawes, and the proceedings then terminated.

CORRESPONDENCE.

LEAD-COATED WIRES ON BOARD SHIP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—Mr. A. A. C. Swinton, in your issue of the 23rd ult., claims, on behalf of Messrs. Sir W. G. Armstrong and Co., the credit of having been the first to introduce lead-coated wires for electric lighting on board ship, naming the Japanese cruiser "Naniwa-Kan" as the vessel in question. According to "Brassey," the vessel was built in 1885. In 1883 I proceeded to the United States of Columbia, Central America, and fitted the electric light on board the Yarrow "stern-wheeler" "Inez Clarke," using lead-coated wires. The installation consisted of a Gülcher dynamo (driven direct by a "Hodson" rotary engine taking steam from the main boiler), 45 "glow" lamps, "B.T.K." storage batteries, and a Gülcher arc lamp. The object of the latter was to disclose "snags" when travelling at night, and thus economise time in running on the river Magdalena between Barranquilla and Honda, a distance of over 600 miles. As I pointed out in the public press on my return in 1884, the object was not accomplished, as, to observers behind the light, it was useless owing to the glare from the water. This has since been found to be the case with naval search-lights.—Yours, &c., C. E. KELWAY.

London, October 5, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—*Alteration of Time.*—The time for sending in the Burnley tenders has been altered from the 26th to the *19th October.*

——— It will be seen by our advertisement columns that the Corporation of York invite tenders for the supply of the first instalment of plant necessary for lighting certain streets, and of a supplementary tender for the supply of additions to the mains and generating plant, such as may be from time to time required to extend the lighting. Specifications and explanatory plans can be obtained from G. McGuire, Esq., town clerk, to whom tenders must be forwarded not later than November 21st.

——— The Bolton Corporation are prepared to receive tenders for a lease of their tramways in the borough of Bolton and the adjoining townships of Great Lever, Halliwell, and Heaton. Tenders to town clerk by the 10th inst.

——— The Wimborne Local Board invite tenders for lighting the public streets of the town and urban sanitary district for three years from the 21st inst. Particulars and forms of tender may be obtained from Mr. H. W. Dibben, clerk to the Board, Poole-road, to whom tenders are to be sent by the 10th inst.

TENDERS ACCEPTED.—The Asylums Committee of the London County Council have accepted the tender of Messrs. Latimer Clark, Muirhead and Co. (Limited), for the electric lighting of Claybury Asylum at £15,130, advertised in our issue for July 1st. As will be seen by the list of tenders which appeared in *The Electrician* of July 29th, this was not the lowest tender submitted.

——— Out of twenty-five tenders received for the electric lighting of the Otterbourne Waterworks, advertised in our issue of September 16th, the Southampton Corporation have accepted that of Messrs. J. G. Statter and Co., Victoria-street, S.W., the amount being £235.

BRUSH ELECTRICAL ENGINEERING COMPANY.—This Company have secured an order for the supply of additional alternating current generating plant and transformers for the Chatham and Rochester Central Station.

MESSRS. JOHNSON AND PHILLIPS.—The contract for the supply of Brockie-Pell lamps for the extension of public lighting in the St. Pancras district has been placed with Messrs. Johnson and Phillips. The district to be lighted includes the Hampstead-road, High-street, Camden Town, and other principal streets.

MESSRS. PYKE AND HARRIS.—This firm have secured the contract for the wiring and fittings of the Grafton galleries.

DIVIDEND NOTICE.—In the estate in bankruptcy of F. G. Williams, lately carrying on business as an electrical engineer, under the title of Kenyon and Co., Crown Point, Denton, near Manchester, a first dividend has been declared of 10s., payable on the 15th inst., at the office of Messrs. J. D. Taylor and Co., Halifax.

Digitized by Google

MESSRS. J. E. H. GORDON AND CO. (LIMITED).—This firm have just issued an elaborately illustrated catalogue of the various central stations which have been erected by the Company, and of others with which Mr. J. E. H. Gordon has been associated. Illustrations are given of the original Paddington Central Station, with which old readers of *The Electrician* are familiar. This is followed by descriptions of eight other central stations, including three in Ireland (Carlow, Larne, and Bray), and one in Scotland (Coatbridge). The illustrations are clearly printed; this remark particularly applies to those of the Carlow installation, an illustration on page 29, showing the interior of a station at Milford, five miles distant from Carlow, being especially good. The frontispiece to the catalogue is a fairly good portrait of the enterprising Mr. Gordon himself. The catalogue consists in all of fifty large folio pages.

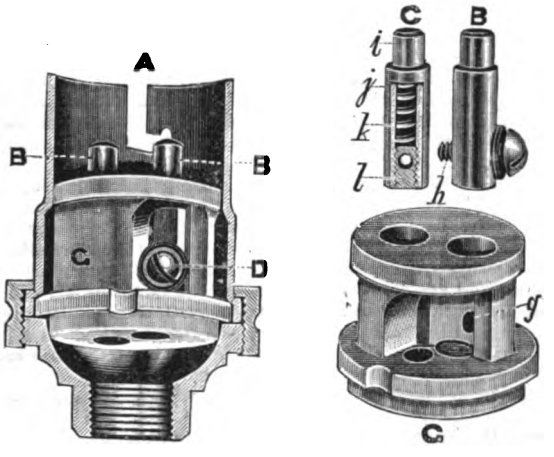
CHANGE OF PARTNERSHIP.—Messrs. Swinburne and Co. inform us that Lord Russell has ceased to be connected with them, and that Mr. Bertram R. Beale has joined the firm, which will continue to carry on the business under the same name.

REMOVAL NOTICES.—The London Battery Company (Limited) have removed from Southwark-street to Marlborough-street, Blackfriars, S.E.

——— Messrs. J. Sunderland and Co. notify removal from Raven-street to Gibbet-street, Halifax.

——— Messrs. Miller and Woods have removed from No. 34 to No. 2, Gray's Inn-road, W.C.

EVERED'S PATENT ELECTRIC LAMPHOLDER INSULATOR.—Messrs. Evered and Co. (Limited), of Drury-lane, London, W.C., and Birmingham, have recently patented an insulator for use with Edison-Swan lampholders of their make. Fig. A shows a cross-section of the holder, with the porcelain insulator in position.



B B are the terminals, D the wiring screw, and G the insulator. In the second figure C is terminal B in section, and shows the method of construction; the solid pin *i* and the nickel spring *k* are put in the socket *j*; the block *l* is then screwed in, and through this block the end of screw *h* passes into the recess shown at *g* in the insulator, thus preventing the terminal from shifting. The insulator is a solid piece of insulating material, not only between the terminals themselves, but also between each terminal and the outer brass cases, the result being that short-circuiting is impossible. By means of a ring of flexible insulating material, which is sprung over the insulator after wiring, loose strands of wire are effectually insulated from the outer case. Messrs. Evered and Co. manufacture these lampholders and insulators complete, and claim that the holders supplied by them have many advantages. They are made of extra stout metal, and are highly finished; the terminals being placed in recesses on opposite sides of the insulating bases, stray strands of flexible wire cannot even accidentally touch; the insulating base is substantially made and not easily broken; the leading-in holes are large enough to admit the insulation of the wires, thus preventing the wires touching beneath the bases; sufficient space is allowed between the base and that part of the lampholder which screws to the electric fitting: and the wires are easily connected by passing between the two washers with which each terminal screw is furnished. A vulcanized fibre collar, which does not come in contact with the current, renders a leakage to earth or a short-circuit on the case of the lampholder unlikely, but we should prefer that porcelain or other equally good insulation be used throughout. We understand, however, that these lampholders have been submitted to the surveyors of the leading insurance companies, and have met with their approval.

ATELIERS HOSTER DE SAINT NICOLAS (LIMITED).—Mr. C. J. Stewart, of 33, Carey-street, W.C., has been appointed liquidator of this Company (in liquidation).

MESSRS. WOODHOUSE AND RAWSON UNITED (LIMITED).—This firm have been placed on the Admiralty List for tenders for the construction of unarmoured wood-built boats, and the supply of engines for the same.

ELECTRO-METALLURGICAL COMPANY (LIMITED).—A meeting is called for November 5th, at 12, at Mr. J. J. B. Arter's, 26, Waterloo-street, Birmingham, to receive an account of the voluntary winding up of this Company.

REDUCTION OF CABLE RATES.—The Direct United States Cable Company (Limited) announce that on and after 1st inst. the tariff to British Columbia and North-West Territory of Canada will be reduced from 1s. 9d. to 1s. 6d. per word.

KIMBERLEY EXHIBITION.—This exhibition has been successfully opened, and the electrical installation appears to have given the greatest satisfaction to all concerned in the opening ceremony. According to the Kimberley papers to hand, the credit of the success of the installation belongs to Mr. R. O. G. Drummond, M.I.M.E.

ANOTHER EXHIBITION.—An Exhibition, to be called the Engineering Exhibition, and which is announced to include Mechanical, Electrical, Marine, and Civil Engineering, Inventions and Patent Models, is to be held at the Agricultural Hall from the 5th to the 12th November next. Mr. John Black, of Newcastle-street, London, W.C., is the secretary.

ABERDEEN.—A new hospital in connection with the Royal Infirmary was opened on Tuesday. The lighting throughout is by electricity from plans by Prof. A. Jamieson. The boilers are Babcock Wilcox, the engines have been supplied by Messrs. Marshall and Sons, and the large belts by Messrs. Tullis and Co. "Castle" dynamos are used. The installation is a very complete one, and patients will have the use of portable lamps, each bed being fitted with a reading and a portable light for examining the patients. A large number of the latest pattern E.P.S. cells are included in the installation.

BELFAST.—At the last meeting of the City Council disappointment was expressed at the absence of any report from the committee specially appointed to inquire into the details of an electric light installation for the city.

BRAY.—The Town Commissioners have decided that the arc lights shall be taken over from October 10th, without prejudice to the form or power of the lamps.

BUXTON.—At the last Local Board meeting, the proposal made by Mr. Willoughby, that the clerk should write to certain leading firms and ascertain the terms upon which they would provide plans and estimates for a considerable installation at Buxton, was agreed to, the chairman stating that before November 29th the Board should decide whether to obtain a Provisional Order or to leave the matter for private enterprise.

CAMBERWELL.—The new Camberwell public baths and washhouses have been formally opened. These baths are lighted throughout by electricity, which has cost £1,500. The installation consists of about 280 lights, the lighting of the swimming baths being effected by means of five-light electroliers suspended from the roof, and the private baths by pendants from the ceiling.

CALCUTTA.—The *Times of India* of September 3rd contains an interesting account of the lighting by electricity of the eastern half of Harrison-road, Calcutta, on the Thomson-Houston system. The installation consists of 19 1,200 c.p. arcs.

CARDIFF.—Some years ago the offices of the *Western Mail* were lighted by the electric light, but the system proved a failure and was abandoned. Last week a return was made to the electric light, of course with success.

CROYDON.—After a long discussion at the last meeting of the Croydon County Council the Corporation determined to keep the borough supply of the electric light in their own hands. The General Purposes Committee has been authorised to report upon the additional expense necessary to extend the installation for lighting the new Town Hall and Library to private consumers within the compulsory area.

DUNDALK.—At a recent meeting of the Town Commissioners a communication was read from the Board of Trade as to the renewal of the Dundalk Electric Lighting License of 1886, in which the Commissioners are recommended to amend their application so as to embrace a Provisional Order in lieu of the license, the form of which is obsolete. The suggestion did not find favour with the Commissioners.

DUNDEE.—The rules and regulations issued by the Dundee Gas Commissioners in connection with the distribution of the electric light has been issued. The price up to 20 units is to be 8s. 4d. per quarter, and 5d. is to be charged for each unit above 20. The rent for meters to be 4s. per quarter for each meter registering one unit per hour to 12s. 6d. per quarter for meters registering 15 units.

GLASGOW.—The steam generating plant for the electric lighting of the City of Glasgow has now been delivered and erected by Messrs. Lindsay, Burnet and Co., of Govan, in the basement of the large new buildings specially erected in Waterloo-street for its reception.

HORNSEY.—At the last meeting of the Local Board a letter from the County of London Electric Lighting Company was considered, asking the Board to offer facilities for including the districts of Crouch Hill and Hornsey in the area proposed to be lighted by the Company, and asking permission for overhead wires; and also asking for a contract for lighting some of the principal thoroughfares. The Committee decided that the Local Board district covers too wide an area, only partially built over at present, for the introduction of the electric light.

LARNE.—The Town Commissioners have had under discussion the question of increasing the electric light in the town, and it has been agreed to confer with the Contractors on the subject.

LIVERPOOL.—The Liverpool Watch Committee, on Monday last, decided to recommend the City Council to adopt the principle of Electric Fire Alarms, and at the meeting of the Council on Wednesday this recommendation was adopted.

WHITEHAVEN.—A stormy meeting of the Whitehaven Trustees was held last week, at which the proposal to borrow for the purpose of an electric lighting installation came under discussion. After the expression of considerable difference of opinion amongst the members of the Board, the proposal to borrow a further £7,000, making in all £21,000, was carried by a majority of 1. It was afterwards decided to extend the installation to several districts not at present included in the scheme for lighting.

COMPANIES' MEETINGS & REPORTS.

Crompton and Company (Limited).

An extraordinary general meeting of the above Company was held yesterday (Thursday) at Mansion House Buildings, E.C., under the presidency of Mr. R. E. Crompton, for the purpose of passing the following resolution :—

"That the capital of the Company be increased to £300,000 by the issue of 22,000 additional Ordinary shares of £5 each, such shares to be numbered 8,001 to 30,000 inclusive, and to rank, as regards dividend and in all other respects, pari passu, with the already existing ordinary shares of the Company, and the Directors are hereby authorised to issue these new shares at such time and on such terms as they may think fit."

Mr. FRANCIS R. REEVES (the Secretary) read the notice calling the meeting.

The CHAIRMAN said: Gentlemen, you will have gathered from the remarks which I made at the last general meeting that our business is increasing steadily, and that fresh capital is consequently required, and you were invited to take up Preference shares at a small premium. Although the response to that invitation has not been to a sufficient extent to yield the extra capital we now require, the Directors do not care to offer the shares to the public at the price named to you shareholders, as we all of us believe that the Preference shares are worth more. After consulting with some of our most influential shareholders, some of those who are connected with the Stock Exchange advised the Board to increase the Ordinary shares, as they considered that the proportion which the Ordinary shares bear to the Preference shares in this Company is far too small. You are probably aware that Mr. Albright and myself, who were the original partners in the private firm of Crompton and Co., are still the owners of the whole of the Ordinary shares. As you know, we took the greater part of our payment in the form of Ordinary shares, carrying deferred dividend, believing it to be the best method of showing our full confidence in the future success of the undertaking, and as a guarantee that we, the vendors, would be as vitally interested in its future success as we have been in the past. Well, gentlemen, we, the ordinary shareholders, have been satisfied with our bargain, but the proposal to increase the ordinary shares certainly appeared to us at first sight to be hard on us and prejudicial to our interests, but after carefully considering the matter in all its bearings, we, who are also the largest holders of Preference shares in the Company, for which we paid cash, feel that the proposed issue of Ordinary shares will not only strengthen the position of the Debenture and Preference shareholders but will be of great advantage to us Ordinary shareholders. As I stated at the general meeting, our business has been a steadily increasing one, and there is no sign that the rate of increase will be altered in any way. During the last few months we have undertaken important contracts, and we have many others in such an advanced stage that we feel sanguine of keeping the works fully employed. Now, what are the prospects of the ordinary shareholders receiving dividends? The dividends that have been paid to us in the past are, I think, not a fair criterion of what will be paid to us in the future. It is difficult for gentlemen who are not closely acquainted with the details of such a progressive business as ours is to believe how greatly our profits in the past have been cut down by the necessity of continually spending money on new inventions, new designs and experiments necessary to enable us to keep our position as manufacturers of the highest rank; but this I can say with some confidence, that never since the very commencement of the existence of the firm of Crompton and Co. has our plant and working organisation been in as perfect a condition and so capable of carrying out our contract work economically and efficiently as at the present time. The fortunes of us managing Directors are so completely bound up with the future success of Crompton and Co. that it has been so evidently our best policy to lay down the foundations of a lasting business by extending our connections in all parts of the world, that I may say that during the last three or four years the large amount of money thus spent has been only sowing the seed for which we have yet to reap the harvest. I will read you an extract from a report of the Pretoria Lighting Company, for which we were the sole contractors. The way they speak of us, their contractors, in this report, I think is fairly representative of the way that we are generally spoken of by our customers throughout the world. After describing the works generally, they go on to say, "Your Directors think that the Company can congratulate themselves on possessing one of the most thoroughly equipped and efficient stations in existence at the present time." And further down they say, "It must be stated that the operations of the Company have been inaugurated in the most auspicious manner. It is almost without record in the electrical world that an installation of the magnitude possessed by this Company should have started and worked smoothly, successfully, and without a single hitch, as has been done in these works since the 10th of June last." From this statement and from the extracts from letters from our South Wales agent, Mr. Howell, who is now in America, it is evident to us that our inventions and the engineering skill of our staff will command a ready market in America if suitable arrangements can be entered into for carrying out work within the United States. The Directors do not entertain for one moment a proposal to invest any considerable capital in America, but it is evident that if the necessary capital can be found outside our own Company, it would be wise policy on the part of our Board to contribute some portion of the capital from the parent Company, and the profit on this capital would very materially increase our future profits. In conclusion, I have to regret the absence of Lord Emlyn, who would have taken the chair at this meeting had he been able to do so, but you are no doubt aware that he occupies the important position of Deputy-Chairman on the Great Western Railway, and he has had to attend a meeting there to-day. The Chairman concluded by moving the resolution as set out above.

Mr. J. F. ALBRIGHT said, in rising to second the resolution, he would not detain the meeting with any lengthy remarks. The Chairman had dilated upon the possible prosperity and future for the Company that might arise if work was started by the Directors themselves or on some thoroughly satisfactory basis in America; but leaving that matter out of the question, he considered that the prospects of the Company were very good, and that the expansion which had taken place in their business quite justified the Board in taking the steps which they now took in asking the shareholders to sanction the raising of additional capital. He had much pleasure in seconding the resolution before the meeting.

There being no discussion, the resolution was put to the meeting and carried unanimously.

A vote of thanks to the Chairman closed the proceedings.

The Brush Electrical Engineering Company (Limited).

The third annual general meeting of this Company was held on Friday last, the 30th ult., at the Cannon-street Hotel, under the presidency of His Grace the Duke of Marlborough.

The SECRETARY (Mr. B. Broadhurst) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, I am pleased to see that we are present in very fair numbers, so that you may hear the statements which will be made by your Directors as to the condition of the Company. It is a very good thing for a Company that its shareholders should take an interest in its affairs, and not, merely because things are prosperous, leave it entirely to the responsibilty of the Directors to appear at a general meeting and address only a few members. At the time when we met here last year I had been Chairman of this Company for only a few months, having taken up this post on the resignation of Lord Thurlow, so that this is the first complete year during which I have had the honour of occupying the chair. Therefore it devolves upon me to pay somewhat more careful attention to the condition of the Company than one would perhaps feel it one's bounden duty to do as an ordinary Director. Now, gentlemen, in drawing your attention to the leading features of our report and balance-sheet, there are a few remarks which I should like to make to you. In the first place, you will observe that your profit and loss account shows a gross profit of £55,757. 11s. 3d., and I will not go into a careful analysis of how these figures are divided, because I prefer to leave it to my co-director, Mr. J. B. Braithwaite, to give you his idea of the incidence of these figures, and how they generally affect the balance-sheet. Therefore I will confine my attention most to some general remarks with regard to these matters. In the first place, we must remember that the balance-sheet of a Company like ours requires particularly careful attention. We are essentially a trading Company—in fact, a manufacturing Company rather than a commercial undertaking. A commercial Company's business settles down to a very secure form. For instance, in the case of a bank, there must be always clients to the bank whether trade is good or bad; to a certain extent, also, the same is the case with a railway company, although, no doubt, in good times there are more passengers and

Digitized by Google

in bad times less. This Company is a manufacturing company, and the business of such a concern depends upon the prosperity of trade and the demand for the particular article of commerce that it manufactures. That brings me to the remark that the balance sheet of a trading company requires very careful attention, and I think it should set forth very clearly, as far as the Directors feel themselves bound to do it, every detail of the Company's affairs. There was one remark made by a shareholder last year with regard to our balance-sheet which I was not exactly prepared to answer at the time, but which has remained in my mind ever since, and that was that there should be some sort of analysis of the statement which appears in the balance-sheet, of the property, patents, and goodwill—£275,321. I was asked why this item was not divided, and I confess at the moment that I was not prepared to give an answer to the question. Now, gentlemen, I have placed the matter before the other Directors, and we have discussed it at considerable length, and have come to the conclusion that in another year we will divide the item. I have no scruple myself in seeing that done because I honestly believe that it will represent good value. It divides itself essentially into two portions. It would not be right to suppose that it was all property ; it would be equally wrong to suppose that it was all patents and goodwill. There is this difference : a trading company essentially possesses goodwill, and goodwill is a legitimate and tangible asset, but it is an asset that is contingent on your existing as a company in a good condition of trade. Supposing your trade fell off—as, for instance, in the case of the silk industry of Coventry—the goodwill there would be worth nothing. Therefore, it is always wise to discriminate in any undertaking between what is property and what is goodwill. Patents are to a large extent difficult to value, and, therefore, I do not think we can discriminate between the value of patents and goodwill. But in another balance-sheet you will see a division of these two items. That brings me to a remark on the general trading of the year. Now, gentlemen, whatever may be the condition of many industries of this country—and some of them have, I think, languished a good deal, trade not having been as prosperous in many directions as we could have hoped—I think in this electrical industry there has been real steady progress. There is no doubt that to a certain extent the industry is on its trial. If there were one or two large electric financial failures connected with those large central station undertakings, I think it would create nervousness ; but on the other hand I see no necessity to have any such fear. As far as I am concerned with the large industry in the City, it affords to me complete satisfaction. I see no prospect of any disaster or difficulty occurring, and, therefore, I think I am right in saying to you that the electrical industry is on an absolutely sound commercial basis ; and as a trading Company you have very good prospects before you. The result of this year's trading has been that you are possessors of a certain abnormal profit this year, and one which cannot always be expected in every year—that is to say, a larger sum has been received on account of the City contract than under ordinary circumstances. Mr. Braithwaite will explain to you how we have dealt with that matter ; but I may briefly say that we have only taken that portion for dividend which would legitimately represent the working profits of the year. Another portion of that profit has been used for writing off certain doubtful items, and Mr. Braithwaite will explain to you how these arose, and why the Directors used those sums instead of writing them off. Another portion of the money has been put to a reserve fund, and, therefore, I say that, taking the general condition of the balance-sheet as it stands, I think it compares very favourably with that of last year. On the other hand, I am bound to point out to you that we cannot look forward to our being always in the same position, unless the trade prospers and increases. There are many competitors in this field, and there is no question about it, we cannot monopolise all the orders. In fact we are obliged, in order to be in a properous condition, to have a very large turnover in the course of a year to be able to present to you what I call a favourable balance-sheet. All these things must be remembered ; and it depends very much on the exertions of your officers and your Board whether we shall be able to keep ourselves in the van of this industry. I must say that I recognise that a great deal of work is thrown on the officers of the Company in this respect ; and in reviewing the events of the year I observe that a very large amount of labour has been bestowed by them in trying to popularise the industry among town councils and local authorities who are likely to adopt the electric light, and I hope that members of the Board will be able to assist in the same direction. In fact, the Directors of the Company must look upon themselves to a large extent as working members in a business rather than as sleeping partners. It is a business that we must have essentially pushed ; and under these circumstances, I have no hesitation in saying that I think you have a very good investment for your money, and a very good prospect for this industry. I will not go critically into the balance-sheet beyond saying a few words on certain points. The policy of the Company, as I told you last year, was to concentrate all the works at Loughborough, and we hope in the course of the year to abandon the works in Belvedere-road, and to carry everything down to Loughborough. The Directors have visited that place several times during the past twelve months, and I can speak to you, as they all can do, most favourably of the manufactory that we possess there. All the engines and dynamos made for the City of London electric lighting contract are of the most approved description, and seem to be everything that could be desired. There are several orders at present in hand, and the prospect of further ones coming in seems to be very satisfactory. You will observe that your debenture issue has been converted during the course of the year, and that you are practically borrowing now a larger sum of money for the same amount of interest. But I notice also in this balance-sheet, a thing which I am bound to call your attention to, and that is that the amount of the premium—£7,500—has been added to the property, patents, and goodwill account, and that is one of the reasons in my mind for the advisability of dividing this item, for it is well that the shareholders should understand how the amount is arrived at, and I desire to point that out to you. Now with regard to the work that has been done for the City of London Electric Lighting Company, that, I think, has met in every respect with the approval of that Company, and I think we shall have no difficulty in carrying out the contract which we have entered into. Of course you will understand that in this industry we are sometimes obliged to undertake work in which there has been no previous experience, and with regard to which we have to compete with other firms ready to give an offer on the same basis, and in such cases the result cannot always be foreseen with certainty. I am glad to say, however, that such cases are not of very frequent occurrence. We exhibited, as you see by our statement in the report, at the Crystal Palace, and the exhibition received considerable attention on the part of the public, and will have done good in bringing the position of your Company before its notice. I will now say a few words with regard to our foreign business. The Australasian trade promises, I believe, to give us a tangible profit in future years. I hope that it may progress, as there is no doubt that our colonies ought to be good customers of this Company. Regarding our Austro-Hungarian business, I may say that at Temesvar it has been acquired by the town for a fixed sum, and I think that the negotiation is practically concluded, and that we may look upon that as an asset which has been turned into money. We have in Mr. Garcke (your former managing Director) a Director who takes a great deal of trouble in the affairs of the Company, and as he was the instrument who concluded this negotiation I feel that we owe a great debt of gratitude to him. With regard to the Vienna business, I hope the day will come—and we all hope it—when we shall be able to hand it over to what I would call a native organisation, and that we shall be able to retain a sleeping interest in the same. There are so many anxieties and difficulties in carrying on an industry of this kind in a foreign country that we should all like to see our business concentrated at one spot, but we have every reason to be satisfied with the year's working. The balance sheet speaks for itself, and with regard to the item of property, patents, and goodwill, I repeat that I think that, though it has descended to us from the amalgamation, it thoroughly represents the tangible assets of the Company, and, therefore, I have every confidence in saying that you may feel satisfied with the result of the year's trading, and that the dividend which you are now to receive is one which has been honestly and fairly earned. I now beg to move the adoption of the report and accounts.

Mr. BRAITHWAITE seconded the motion, and in doing so said that as the Chairman had pointed out, in a trading company the balance-sheet might be made the means of covering up the true position of a company or of exhibiting it. In their case, the balance-sheet was one that would bear the closest investigation. In dealing with the profit and loss account first, he wished them to bear one figure in their mind, and that was that to pay 6 per cent. required £7,000 for the half-year, and to see the amount that they had written off that year, and the amount of prudence which they had exercised. The gross profit, as stated in the balance sheet, £55,757, had been arrived at after making most ample provision for anything that seemed as if it might turn out unsatisfactory in future years. They had received this year the initial payment for their large contract with the City of London Electric Lighting Company, and they had written off £4,336 as a provision against loss incurred in respect of some orders carried out in foreign countries. The financial position of some of those countries had been unsatisfactory recently, and they thought it better to write off the whole of that sum. They had also written off the entire costs in connection with the action brought against them by Messrs. King, Brown and Co. They had also made a provision of £4,000 for any possible further bad debts that might arise, although they had not any in sight. Therefore, it might be said that they had been ultra-cautious ; but it was their duty, in a Company like theirs, to be extremely cautious in their policy. Then they had written nearly £1,000 off their Provisional Order Account, and another £1,000 in connection with the opening of their show-rooms in Regent-street and the City, which might have been spread over a series of years, so that it would be seen that the gross profits brought into the balance-sheet might have been made to appear very much larger. But he thought that the shareholders would agree with the Board in placing the Company in a thoroughly sound financial position. It would be observed that their standing charges had apparently increased by nearly £5,000. That was made up of items which he would call their attention to. In the first place there was the cost of their exhibition at the Crystal Palace, which was invaluable to the Company. It had cost £2,172, and the whole of that amount had been absolutely written off this year, instead of spreading it over a series of years, which might have been done. The staff bonuses had also increased. As the shareholders were aware, the Company were working on the profit-sharing system, and although they had made but a moderate amount of progress with it what they had done was satisfactory. They had 64 of their officers and *employés* on the bonus list, and it was their expectation to make an extension of the system by which the weekly wage-earners would benefit. He believed that this was the best way of dealing with the labour question, namely, to identify the interests of the men with those of the Company by which they were employed. Although there had been an increase in the standing charges this past year, they might, if not next, at least the following year, expect to see a considerable decrease in that item. They were now erecting at Loughborough an additional factory, which would enable them to concentrate their whole works there. By the removal of the whole of their operations to one place they would effect a great reduction in the fixed charges. It was hardly likely that they would be able to move altogether before the beginning of next year, so that only a portion of the benefit would appear in the next accounts, but in the following twelve months the decrease in the standing charges would be more apparent. The Chairman had already dealt with the item of property, patents, and goodwill, as well as that of

Digitized by Google

the redemption of debentures, £7,500, which arose in a manner which was directly beneficial to the Company. They had £75,000 Six per Cent. Mortgages of the Company which they had an option of redeeming at 105 on December 1, 1892, but to save time they had issued £125,000 Four and a-Half per Cent. Perpetual Debenture Stock, granting £110 of the new Four and a-Half per Cent. Stock for every £100 Six per Cent. Mortgage Debenture. This had effected a considerable economy in interest to the Company. The whole of those debentures had been redeemed on that basis. A large portion of the holders accepted these terms; and the balance was taken from them by a firm of brokers to complete the conversion. The result of that conversion showed the satisfactory credit in which the Company stood, and when a quotation was asked on the Stock Exchange, the price would be likely to stand at a considerable premium. The new arrangement gave them £18,500 additional capital, without costing them sixpence, which was a beneficial operation for the Company, and fully justified the action of the Directors. The next item was stock, from which they would see the thoroughly sound position they were in. The figure of stock in process of manufacture altogether amounted last year to £78,236, and this year it was £77,990, or practically the same figure. The shareholders, therefore, would see what that fact implied. It meant that they had sold the whole of their output; they had also disposed of some £4,000 or £5,000 worth of obsolete material, and that had been replaced by stock which had a ready market. The expenses of share and debenture issues, £1,743, he thought would be regarded as moderate in view of the benefits received. With regard to the Debenture Stock the amount shown in the balance-sheet as issued was only £111,347, the total authorised issue being £125,000. They would be glad to know that the balance of that stock had been issued and placed so that the whole amount now would be quoted in the market. As to the reserve account, that, as the Chairman had explained, arose out of their contract with the City of London Electric Lighting Company. In this connection they were asked to do an unusual thing. They were asked to take a contract under very stringent conditions for delivering certain machinery for producing a certain amount of electric power, and the machinery was such as had never been made before. In view of the fact that they were asked to give a binding contract, it was necessary to add a certain sum for contingencies beyond what they would have done under ordinary circumstances, to provide against the loss they might sustain by making the experiment of producing those unusually large machines He thought, therefore, it was a very wise course to adopt to carry a certain amount to a contingent fund. If all their machines turned out satisfactorily, the reserve sum of £15,000 would become an asset, available for dividend in future years; but he thought they were wise in keeping it in hand to meet any possible mishap that might occur in course of carrying out the contract. He did not know that there was any other point to which he need call attention, except to say that they proposed to reduce their property by another £3,000, and to take £800 for preliminary expenses and carry forward £753. They had eliminated every possible source of weakness in the accounts, and he thought that the dividend-paying prospects of the Company were distinctly bright. They might have paid a much larger dividend on this occasion, but he believed the shareholders would support the policy the Board had adopted. If there was any change made it would be in the direction of increasing the distribution on the ordinary shares. He had great pleasure in congratulating the shareholders in having entered at last on a career of commercial success, which so many of them had looked forward to through long years of waiting, difficulty, and cloud. He thought that they were fairly out of the wood, and on the high road to prosperity.

Mr. CHAS. R. FRY said after the clear statement given by the Chairman and Mr. Braithwaite, it must be received by the shareholders with great pleasure. The latter gentleman had referred to the question of the issue of increased capital to the amount of £11,000. Now, if they looked to the other side of the account they would see an item "by expenses of share and debenture issues, £1,743. 6s. 7d," and the information he wished to ask was this: How was it that the Company received only par value for those shares while the expense of the issue stood at such a high figure? If anybody would take the trouble to look at the official prices quoted on November 1, 1891, he would see that the shares of the Company stood at a considerable premium. He wished also to ask when the shares were issued and to whom they were allotted.

The CHAIRMAN said that so far as he knew the Directors had no interest whatever in the issue of the shares in question, nor had they taken any of them.

Mr. BRAITHWAITE explained that there were a small number of preference shares uniasued, and as the Board could at the time of the issue usefully employ a little capital in the extension of their works, he had been instructed by the Board to see whether he could not get a bid for the shares. He communicated with various dealers in the market—he was sorry Mr. Fry was not invited—to bid for them, and two or three of those dealers joined together and gave a bid for the whole lot at par. The shares were about par in November, 1891; therefore, he did not think they had done badly. They got the whole of the capital without going to the expense of circularising the shareholders and advertising so trivial an issue.

The CHAIRMAN said that there was a very great difference between buying and selling shares, and as to the services of Mr. Braithwaite as broker of the Company he (the Chairman) could say, having sat at the Board and knew it, that the Company would not have been in existence but for the efforts exerted in its behalf by that gentleman.

A SHAREHOLDER said that a circular should have been sent round to the shareholders to give them the first call on the shares. Anyone would have been pleased to take them over on the terms offered.

Mr. BRAITHWAITE was exceedingly sorry that the gentleman who had just spoken had not also been invited to take the shares up. The preference shares had never been at ¾ premium, as had been alleged.

Another SHAREHOLDER thought that there had been too much speculation in the shares of the Company.

The CHAIRMAN said he had never bought or sold a single share since he had been a member of the Board, and so far as he knew this statement applied to every other member.

Mr. BRAITHWAITE said that the 25,000 shares were offered to the shareholders, and now that the Company was on the high road to success, some of them regretted that they did not avail themselves of the offer.

Mr. FRY said they never had any chance given to them.

Several shareholders spoke in support of Mr. Braithwaite's contention.

The CHAIRMAN said that he thought they were perfectly justified in paying a dividend of 6 per cent. The position of the Company was far more satisfactory than at any previous time. He would not have been willing to see a higher distribution made, because he thought that the items referred to should be written off, not in the course of years, but in one year. He then put the motion, which was carried.

On the motion of the CHAIRMAN, seconded by Mr. BRAITHWAITE, a dividend at the rate of 6 per cent. per annum on both preference and ordinary shares was then declared.

Mr. COPLAND proposed, and a SHAREHOLDER seconded, the re-election of Messrs. E. Woods and E. Garcke to their seats at the Board.

The motion having been carried,

Mr. SMART proposed the reappointment of the auditors, Messrs. Cooper, Bros. and Co., with an increased remuneration of 100 guineas.

Mr. COPLAND seconded the motion, which was carried.

Mr. FRY proposed a hearty vote of thanks to the Chairman.

A SHAREHOLDER seconded the motion, which was cordially passed.

The CHAIRMAN having expressed his acknowledgment, the proceedings terminated.

Pretoria Lighting Company (Limited).

The following is the Directors' report for the period ended June 30th last to the shareholders of the Pretoria Lighting Company (Limited):—

Building and Machinery Contracts.—The contract for the station buildings was placed in the hands of Messrs. Murdoch and Haldane, who have executed their work to the satisfaction of the Board. Messrs. Crompton and Co. (Limited) handed over the electrical machinery and plant on June 1st last. Your Directors called in Mr. J. Hubert Davies, electrical engineer of Johannesburg, to inspect the whole of the works. Mr. Davies has sent in a preliminary report, and will send in a final one after September 1st, when the three months' trial run of the machinery by the contractors is concluded.

The shareholders will remember that Messrs. Crompton and Co. (Limited) bound themselves under a penalty clause to complete their works by March 31st last. As this was not carried out, this matter was also referred to Mr. J. H. Davies, who advised your Board that good and valid reasons had been advanced by Messrs. Crompton and Co. (Limited) for the non-fulfilment of their undertaking.

The Extension System.—On the arrival at Pretoria of Mr. J. Cushny (Messrs. Crompton and Co.'s representative) it was discovered that the original system of distributing the mains was unsatisfactory and unworkable.* A new plan was devised (involving an additional expenditure of rather less than £3,000), which your Board sanctioned, and which is now nearly completed, whereby the distribution of the electric current is made available at every house within the boundaries of the city.

The Electrical Machinery.—The plant consists of five sets of boilers, engines, and dynamos, together with 102 lamps for street lighting, with all poles, insulators, &c.; about 36 tons of copper conductors, distributed on the underground and overhead systems; and with all necessary instruments required for a central station. Your Directors think that the Company possess one of the most thoroughly-equipped and efficient stations in existence at the present time. The plant is capable of supplying current to about 6,000 8 c.p. lamps, in addition to the public lighting contract.

Supply of Current.—The Company started on June 10th last the supply of light to 48 of the public lamps, to the State printing office, and to a few private consumers. The whole of the public service could not be started simultaneously, as a certain number of the lamps are on the extension system, which will not be finished until September 1st. Up to date 72 private installations have been, or are being, connected to the Company's mains. A full statement of all installations made up to the date of the general meeting will be laid before the shareholders for inspection.

Management.—The Directors have secured the services of Mr. John Cushny, resident engineer, the appointment to date from Sept. 1st next, and have appointed Mr. Hirschel Cohen to the dual position of manager and secretary.

Messrs. C. Hanau and J. B. Taylor retire in order of rotation, but are eligible and offer themselves for re-election as directors. A new auditor (or auditors) in the place of Messrs. Cowen and Wilkinson, who have left the State, and the confirmation of the appointment of Mr. A. Scott Rankin as auditor of the present accounts (and as to his remuneration), will form a portion of the business at the forthcoming meeting of the shareholders.

The report concludes with the announcement that the Directors have decided that the amount of £4,543. 5s. 8d. expended during the past three years on the various items effecting the formation of the Company, and

* With reference to the above report (under the heading "The Extension System") it should be stated that the necessity for re-arranging the original system of distributing mains was owing to no fault of Messrs. Crompton and Co., who worked to the designs of the original engineer to the Pretoria Company, whose position is now occupied by Mr. Cushny, as stated above. Messrs. Crompton and Co. are certainly to be congratulated upon the success of the Pretoria installation.

other amounts not directly chargeable to the construction account, shall be written off over a course of seven years, and the amount that will consequently be charged annually to profit and loss account will be £649. 0s. 10d.

NEW COMPANIES, STATUTORY RETURNS, &c.

CARBON BATTERY COMPANY (LIMITED).—This Company was registered on September 28th, with a capital of £10,000, in £1 shares. The objects are to manufacture, sell, and deal in electricity, and the bye products arising from the manufacture thereof, to manufacture, sell, and deal in aluminium, and metals alloyed with aluminium, magnesium, and other metals, and in chemicals and other substances arising out of the manufacture or otherwise; to purchase or otherwise acquire letters patent for the following and other inventions:—"An improved process for the manufacture of electricity direct from carbon; the recovery and purification of the bye products arising therefrom, and apparatus therefor," and to develop, turn to account, exploit, grant licences in respect of, and manufacture in accordance with, the said and other inventions. The subscribers are:—S. Willington, 28A, Basinghall-street, E.C.; F. A. Freeland, 11, Richmond-road, Barnsbury, N.; Charles E. Jolly, 29, St. George's-road, N.W.; Henry Russell, 74, Chancery-lane, W.C.; Leopold Herz, 49, Grosvenor-road, Highbury New Park; Charles H. Russell, 34, Chapter-road, N.W.; John T. Shrives, 337, High Holborn.

NEW ELECTRO-METALLURGICAL SYNDICATE (LIMITED).—This Syndicate was registered on September 28th with a capital of £10,000, in £1 shares. The objects are to acquire, develop, turn to account, grant licences in respect of, and manufacture in accordance with, an invention for "an improved process for the production of metals by electrolysis and the recovery and purification of the bye products arising therefrom and apparatus therefor."

Similar in capital, shares, and signatories to the above Company there have also been registered the **New Glass Syndicate (Limited)** which proposes to exploit, develop, and turn to account certain inventions relating to the manufacture of glass; and the **New Sulphur Recovery Syndicate (Limited)** which will deal with the manufacture of sulphur and the utilisation of its bye products.

MISCELLANEOUS.—BUTE DOCK FOUNDRY (LIMITED), iron and brass founders, mechanical and electrical engineers, steel converters, &c.; capital, £10,000, in £5 shares.——UNITY ELECTRO-PLATING COMPANY (LIMITED), electro-platers, silversmiths, and jewellers, carried on by J. B. Finnemore at 125, Great Charles-street, Birmingham; capital, £5,000, in £5 shares.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The first annual return of the above-named Company, made up to September 15th, was filed on the 27th. Out of a nominal capital of £800,000, divided into 40,000 ordinary and 40,000 preference shares of £10 each, 39,006 ordinary shares have been taken up, and the full amounts called, resulting in the payment of £38,998, and leaving £62 in arrears.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The annual return of this Company, made up to June 24th, was filed on September 29th. The nominal capital is £307,545, divided into 75,000 £6 per Cent. Preference Shares of £1 each, 224,850 ordinary shares of 14s. each, and 75,150 ordinary shares of £1 each. £7,637 preference and 224,850 ordinary shares have been taken up, the full amount called, and all calls (£185,032) paid.

D. HULETT AND CO. (LIMITED).—The annual return of this Company, made up to September 12th, was filed on the 16th, The Company was registered on July 30, 1889, with a capital of £35,000, divided into 6,900 ordinary and 100 founders' shares of £5 each. At the time of making up, 5,900 ordinary and the founders' shares had been taken up, of which 4,000 ordinary and the founders' shares had been issued as fully paid. Upon the remaining 1,900 ordinary shares the full amounts had been called, and all calls (£9,500) paid.

HALIFAX MUTUAL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to August 20th, was filed August 29th. The Company was registered on March 27, 1889, with a capital of £20,000, in £5 shares. At the time of making up 1,226 shares had been taken up, of which 105 had been issued as fully paid. Upon the remaining 1,121 shares, £3. 10s. per share had been called, resulting in the payment of £3,926 (which includes a sum of £2. 10s. paid on five forfeited shares).

HEAD, WRIGHTSON AND CO. (LIMITED).—The second annual return of this Company, made up to July 2nd, was filed August 23rd. The Company was registered on June 21, 1890, with a capital of £210,000, in £5 shares. At the time of making up, all the shares had been taken up, the full amounts called and all calls paid. Share warrants to the total amount of £24,270 (4,854 shares) are outstanding, and share warrants to the total amount of £730 (10 warrants of 10 shares each, 2 of 20 shares each and 1 of 1 share) have been surrendered since last summary.

KEIGHLEY ELECTRICAL ENGINEERING COMPANY (LIMITED).—The statutory return of this Company, made up to May 6th, was filed on August 2nd. Out of a nominal capital of £10,000, in £1 shares, 2,408 shares have been taken, of which 2,400 have been issued as fully paid. Upon the remaining eight shares the full amounts have been called, and all calls paid. By an agreement dated July 19, 1892 (filed August 15, 1892), between Henry Boardman, Ira Ickringill, and Charles J. Garnett, and the Company, the Company allotted to each of the vendors 300 fully-paid shares in consideration for certain patents and patent rights, particulars of which are not given.

LAING, WHARTON, AND DOWN CONSTRUCTION SYNDICATE (LIMITED).—The annual return of this Company, made up to August 3rd, was filed on August 5th. The Company was registered on March 18, 1889, with a capital of £40,000, in £100 shares, which has since been increased to £100,000 by the creation of 6,000 shares, of £10 each, and the 400 shares, of £100 each, have been subdivided into 4,000 shares, of £10 each. At the time of making up 4,716 shares were taken up, of which 1,330 had been issued as fully paid. On 2,660 shares the full amounts had been called; on 397, £2. 10s. per share called; and on 329 shares £5 per share had been called, resulting in the payment of £29,237. 10s.

MADRAS ELECTRIC TRAMWAYS COMPANY (LIMITED).—The statutory return of this Company, made up to July 28, 1892, was filed on August 9, 1892. The nominal capital is £100,000, divided into 100,000 shares of £1 or Rs.15 each. 14,000 £1 shares have been taken up, 5s. per share called, and all calls (£3,600) paid; 6,273 shares of Rs.15 each have been taken up, Rs.4 called on each, and up to the time of the last advice from India, August 8, 1892, Rs.12,546 had been paid, leaving a similar sum in arrears.

MIDLAND ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to September 14th, was filed on the 23rd. The Company was registered on December 12, 1681, with a capital of £50,000, in £10 shares; and at the time of making up 3,139 shares had been taken up, of which 3,132 had been issued as fully paid. The full amounts have been called and paid on the remaining seven shares.

NEW CADOGAN AND BELGRAVE ELECTRIC SUPPLY COMPANY (LIMITED).—At Extraordinary General Meetings of the above-named Company, held at the offices, 91, Manor-street, Chelsea, S.W., on June 20 and July 6, 1892, the following special resolutions were duly passed and confirmed:—(1) "That the name of the Company be changed to 'The St. Luke's Chelsea Electric Lighting Company (Limited)'"; and (2) "That the capital of the Company be increased to £30,000 by the creation of 2,900 new shares of £10 each." The official notices of such increase were filed on July 14, 1892, the permission of the Board of Trade for the said change of name granted on July 20, 1892, and the certificate issued July 22, 1892. The Company was registered on June 30, 1890, to carry on the business of the Cadogan Electric Light Company (Limited). The last return (filed January 7, 1892) showed that only seven shares had been taken up and no calls made.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The accounts of this Company, subject to audit, show a profit sufficient to enable the Directors to recommend a final dividend of 3s. per share, making, with previous distributions, a total dividend of 6 per cent. for the year ended June 30th last, and also the payment of a bonus of 1s. per share, both free of income-tax, which together will amount to £26,000, leaving a balance of £43,073. 8s. 5d., of which amount £40,000 has been placed to the reserve fund, increasing that fund to £579,714. 6s. 1d., and £3,073. 8s. 5d. is carried forward. For the purpose of paying the above dividend and bonus on the 20th inst. the register of transfers will be closed from the 10th to the 19th inst., both days inclusive.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—Letters of allotment and regret in respect of the recent issue of £200,000 Six per Cent Cumulative Preference Shares were posted yesterday.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended October 2nd were £786, as against £748 for the corresponding period of last year, being an increase of £38. The total receipts for half-year amount to £10,757, against £9,874 in the corresponding period of 1891, being an increase of £883.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts for the month of September were £3,100, as compared with £3,055 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the month of September were £2,011, against £2,004 for the corresponding period last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of September amounted to £55,710, and to £56,589 in the corresponding period of 1891, a decrease of £879.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of September amounted to £42,585, and to £40,585 in the corresponding period of last year, an increase of £1,999.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—Sir Daniel Cooper, Bart., has been appointed Vice-Chairman of this Corporation, vice Mr. J. S. Balfour, M.P., resigned.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for September amounted to £24,000; and from January 1st to September 30th to £199,600. In the corresponding months of 1891 and 1890 the amounts were £213,400 and £206,800 respectively.

SOUTH AMERICAN TELEGRAPH COMPANY (LIMITED).—This Company announce the opening of a new submarine route between Europe and South America by the Company's cables from Senegal to Pernambuco, in connection with the Spanish National and Eastern Companies' systems between London and Cadiz. The Company has opened receiving offices for messages at 106, Cannon-street, and 27, Royal Exchange. Telegrams can also be handed in at the offices of the Eastern and Direct Spanish Telegraph Companies. Messages for this Company's lines are to be directed "via Teneriffe."

Digitized by Google

REUTER'S TELEGRAM COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend at the rate of 5 per cent. per annum, free of income tax, for the half-year ending June 30th last, payable on the 12th instant.

SUBMARINE CABLES TRUST.—Notice is given in our advertisement columns that on and after the 15th inst. the sum of £1. 10s. on account of the coupon due October 15th next will be paid by Messrs.-Glyn, Mills, and Co., at 67, Lombard-street, between 10 a.m. and 2 p.m. The coupons should be left with the bankers for examination four clear days before payment.

TELEPHONE COMPANY OF AUSTRIA (LIMITED).—The Directors of this Company have declared the usual half-yearly dividend of 6 per cent. on the preference shares, payable forthwith.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the fortnight ended Sept. 30, 1892, were £2,470, compared with £1,602 for 1891, showing an increase of £868.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Sept. 30, 1892, were £3,613.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 752.—Vol. XXIX. FRIDAY, OCTOBER 14, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6*

NOTES.

In the course of the discussion on a National Physical Laboratory at the last meeting of the British Association, Lord Kelvin said, "If any private individual will come forward with £500,000 to endow the nation with a physical laboratory, certainly the gratitude of the world will be accorded him. But if it is of national importance, is it dignified that we should wait for a millionaire to do it? It is a very poor argument to use to the Government: 'If you wait long enough there may be a chance of some millionaire in this country or in America doing it for us.'" With true scientific disinterestedness he appeared to suggest that whether such an establishment be founded in this country or elsewhere would be of small moment, so long as the cause of science was advanced. But the arguments for Government endowment were not, as a whole, remarkable for their cogency, and consisted chiefly in pointing to Germany and asking why England should not do likewise.

There are, we think, weighty reasons for preferring that a National Physical Laboratory should be independent of Government patronage and control, quite apart from any socialistic or individualistic principles. Although the building and equipment of the Imperial Institute is an extraordinary example of what can be done by public subscription prompted, only indirectly, by utilitarian considerations, it would be extremely difficult to rouse a £500,000 enthusiasm for five-figure physical determinations. In common with Prof. Fitzgerald we have recently called attention to the economy of utilising, if possible, one or several of the existing establishments as a nucleus for such a laboratory, and the munificent donation of £20,000 by Mr. Thomas Hodgkins, of Setanket, to the Royal Institution, to be applied in the promotion of scientific research, seems to point out the direction in which we can best give scope to our English instinct for infusing new life into old institutions.

The Royal Institution has always been connected with pure research, and supported as it is largely by the intelligent public, who can claim little connection with science other than forming attentive audiences at lectures and discourses, its services to science and especially to physical science can never be gainsaid. To the names of Young, Davy, Faraday and Tyndall may be added Rayleigh and Dewar. The important researches upon the liquefaction of oxygen, and the still more important investigations which have been commenced, with the assistance of the powerful refrigerating apparatus thus afforded, are the outcome of the presentation of considerable sums by individual subscribers. The efficient application of such a sum of money as that which Mr. Hodgkins has given is rendered much more likely when it is received by an institution in full working order, and with all the prestige of an historic past, than when a large part of it has to be spent in bricks and mortar and in starting a brand new organisation. The energy of the money thus spent becomes latent. We do not hesitate to use the term energy, for by it we mean the power of doing work; and not only is it latent, but in suffering a change of state, the money goes out of the world of science into the building trade. We hope that the efficiency of conversion of this £20,000 into scientific research will encourage other benefactors to turn some of their balances into kinetic cash, and thus bring the establishment of the much-needed national physical laboratory within measurable degree of realisation.

We publish this week a communication from Mr. Walter Judd, the Eastern Extension Telegraph Company's Manager in China, on the subject of Submarine Cable Relays, which will be read with interest. The modesty which characterises the confession of these comparative failures is not less noteworthy than the perseverance and ingenuity displayed in the experiments described. We have only one fault to find with descriptions of this kind, namely, that they do not come to hand more often. Fruition, it is true, is the great object of all experiments; but very much may be learnt from essays in the direction of success, though they fall short of it; and we fancy that the problem of cable relays, like many other difficult tasks, would be sooner solved, if experimenters would let the rest of the world know what they have been trying, and what has been the cause of their lack of success.

We note that the Town Council of Wigan, which, by-the-bye, owns the Gas Works, has received less than ten favourable replies to a recently-issued circular with regard to the adoption of the electric light. We do not know how the Wigan circular was worded, but if it was anything like as pressing an invitation to take the electric current as is usual where a municipality owns the Gas Works, the meagre response probably did not surprise the authorities concerned. We remember a similar circular which opened somewhat as follows:

Digitized by Google

"Assuming that electricity will cost you x times the price of gas, are you prepared to take a supply in the event of the Gas Committee laying down an electric lighting plant?" The correct answer to this equation is, of course, negative.

THE printing of mathematical symbols, to which Mr. MITCHELL refers in our Correspondence columns this week, is a matter of considerable importance, both to writers and to readers, as well as to those who are responsible for bringing these two sections of the community into communication. A matter quite as serious as the ease of setting the type is the legibility of the author's writing. Some authors write their indices or exponents well above the line, but too often they "cock them up," to use the printer's expression, almost imperceptibly. Anything that will help to make the author's intention (we will not say his meaning) clear would be welcome. Prof. S. P. THOMPSON has made a suggestion which has one excellent feature, namely, that the expression runs on in a single line. The trouble of setting the symbols $\frac{dy}{dx}$ is so much greater than setting dy/dx, that the line containing the former counts as six lines to the compositor. This is explained by the fact that spaces must be specially cut to fill up the "whites" between the lines, and these "whites" are moreover very unsightly. While Prof. S. P. THOMPSON's notation $A\,exp[-ax]$ avoids this difficulty, Mr. MITCHELL's arrangement does not do so. It will be observed that the "leading" of his letter is irregular. "Leads" have to be specially cut to fit the bit of "rule" above or below the line, and this line, therefore, counts as two. The / , called the solidus or shilling mark, is to be found in all complete founts of type, but the \ would have to be specially cast for those writers who employ them, unless one of the compositor's ingenious makeshifts could be used. We must confess that Prof. S. P. THOMPSON's proposed notation is not altogether satisfactory, for the "cocking up" of the index conveys at a glance the suggestion of being *raised* to the power far more clearly than the letters *exp*. The solidus should be used when a fraction occurs in the course of running text, but when mathematical work is "displayed" or set out, there is not much advantage in its use. The solidus cannot be used where there is more than one term in the numerator or denominator. The expression, for example, $\frac{I\,m - L\,\omega}{I\,m + L\,\omega}$ cannot properly be written $I\,m - L\,\omega/I\,m + L\,\omega$. With regard to the disappearance of the ϵ to which our correspondent alludes, we can only say that Prof. S. P. THOMPSON's letter to *Nature* was faithfully reproduced in our Notes last week. Finally, owing to the increase in technical literature and the consequent use of mathematical symbols, the question of cost should by no means be lost sight of. If some simple method of expression could be devised it would have an appreciable effect upon the cost of scientific books.

ALTHOUGH there seems to be no end to the variety of lampholders, cut-outs, and switches that are now on the market, ingenuity seems to be spent upon innumerable modifications of a few types of fittings rather than upon real novelties. That several devices which we could name are rarely, if ever, to be found in such catalogues as the elaborate one which Messrs. VERITY AND SONS have just issued, may, of course, be accounted for by the fact that there is little or no demand for them. On the other hand, the demand for regulating sockets, by which the light of a glow lamp can be reduced either by a resistance or by a choking coil, has been met by the frank admission that such a contrivance effects practically no saving of current, and they are, therefore, rarely seen.

WALL-PLUGS and sockets are becoming common now that they are combined with switches, but it would often be convenient to be able to attach a portable or a temporary lamp to a fixed lampholder. For this purpose a plug of the B.C., E.S. or other type, to fit the lampholder in place of a lamp would be very useful. Such a plug, if well-designed, might be used for ordinary wall sockets, the sockets being arranged like lampholders, but perhaps with more substantial contacts and bayonets. Cauteries, laryngoscopes, &c., might be thus attached by medical men who need not carry cumbersome batteries into electrically-lighted houses. Two- and three-light "bodies" or "balls for clusters" are often used and are specially wired, but it would sometimes be convenient to attach such a fitting to a lampholder for festive occasions, and a plug to fit in place of a lamp would enable this to be done with ease, providing always that the fuses were suitable for protecting the permanent wiring.

Electric Light Legislation.—An Electric Lighting Bill has just been brought forward in the Victorian Parliament.

Personal.—Mr. Denny Lane, Secretary of the Cork Gas Consumers' Company, has been appointed a magistrate for the City of Cork.

Cavendish Laboratory.—Mr. W. C. D. Whetham, B.A., Fellow of Trinity College, has been appointed Assistant Demonstrator of Physics in the Cavendish Laboratory.

Military Projectors.—A powerful projector has been mounted at Fort d'Embourg, Liège, to light up the valleys dominated by the fort and also the outworks of the neighbouring forts.

Islington Vestry.—A motion which was brought before this vestry at its last meeting to postpone further proceedings in connection with obtaining an electric lighting Provisional Order was defeated by 39 to 15 votes.

Paris.—Only 20,000 houses out of a total of 85,000 use gas in Paris, their consumption for 1891 being about 10 million thousand cubic feet. The number of 8-c.p. glow lamps connected to supply companies' mains is about 175,000.

The Leeds Electric Tramway.—At the last meeting of the Leeds Town Council the agreement with Mr. Graff-Baker for the working of the electric tramway to Roundhay Park, which expired yesterday, was extended for a period of 12 months.

Electric Travelling Cranes.—The Gas Committee of the Manchester Corporation have decided to erect an electric travelling crane for unloading the coal barges and distributing the coal at their electric lighting station. The contract has been given to Messrs. Mather and Platt.

Transformer Efficiencies.—In a recent number of the *Elektrotechnische Zeitschrift* appeared some *calculations* by C. L. Imhoff relative to the comparative efficiency of "core" and "shell" transformers, by which is meant transformers with the windings outside and inside the iron respectively. According to these calculations, the "shell" type is the better of the two.

Wolverhampton.—At the last meeting of the Town Council the recommendation of the Streets and Lighting Committee

Digitized by Google

that a plot of land in Commercial-road should be bought from the late Mr. Walford's trustees at a cost of £1,900 was agreed to.

L'Association Française pour l'Avancement des Sciences.—The twenty-first meeting of this association was held this year at Pau from September 15th to September 21st. Prof. Crova read a Paper on "Photometry," a new accumulator of M. Edouard Peyrusson was described, and Dr. Gautier read two Electro-Medical Papers.

The Telegraph in Mexico.—Since April last the Federal Telegraph system has gained 1,500 kilometres of new lines, the aggregate length of its lines being now 35,500 kilometres. Material is already on hand for the construction of new and important lines. Work on these lines will be undertaken as soon as the rainy season is over.

Royal Institution.—The treasurer of the Royal Institution has received from Mr. Thomas Hodgkins, of Setanket, Long Island, New York. the munificent donation of £20,000 to the funds of the institution, to be applied in the promotion of scientific research. Mr. Hodgkins recently presented £40,000 to the Smithsonian Institute at Washington.

Railway Lighting.—It is stated that owing to the success of the introduction of electric lamps for the use of passengers on the District Railway, an additional order has been decided upon, and also that it is the intention of the Midland and several other of the railway companies running out of London to follow the example of the District Company.

St. Pancras.—At the St. Pancras Vestry meeting on Wednesday last, it was explained by Mr. A. Sweet, Chairman of the Electricity Committee, that no rate would be required to be levied in respect of electric lighting purposes. Applications for the electric current were received from residents on the west side of Gorden-square, and it was decided to lay down a main for the purpose.

Electrical Connection of Lightships with the Shore.—Mr. Allen Stoneham, formerly Registrar-General of Shipping and Seamen, and lately an Assistant-Secretary to the Board of Trade, has accepted the appointment of Chairman of the Committee on Lightships, and their construction, &c. Part of the reference to the Committee is the practicability of establishing electric communication between lightships and the shore.

Research Scholarship.—Her Majesty's Commissioners for the Exhibition of 1851 have placed at the disposal of the Council of University College, London, the nomination to a scholarship of £150 for the year 1893. The scholarship is intended "to enable students who have passed through a college curriculum to continue the prosecution of science with the view of aiding in its advance or in its application to the industries of the country."

Wigan.—A question was asked at the last meeting of the Town Council as to the intentions of the Gas Committee with regard to the electric light. In reply, the Chairman said that only eight or nine people had replied in the affirmative to the Council's circular. This being so, the Committee did not think they were justified in spending £30,000 or £40,000 on the matter; nor would such a state of affairs justify any private venture in that direction.

Rangoon.—The *Indian Engineer* reports that a letter has been received from the Edison-Swan Company by the Municipality of Rangoon, offering to light Rangoon with electricity for the same cost as oil. The same number of electric lamps as there are now oil lamps would be supplied, but giving three times the light. A concession for fifty years is asked for. The Company guarantees 5 per cent. of the net profits to the Municipality.

Maidstone.—At the last meeting of the Local Board the subject of electric lighting was discussed at great length. In the end the recommendations of the Electric Lighting Committee were passed in an amended form, and the plans were ordered to be approved of by the Board before being carried out. Mr. W. C. Hawtayne was directed to prepare the plans, and to act as resident engineer for twelve months after the completion of the electric light works.

Cork.—At a recent meeting of the Committee of the Corporation having charge of the question of the introduction of electric lighting, it was decided to recommend the Council to refuse consent to the application of the Cork Gas Consumers' Company for an Electric Lighting Provisional Order. The Committee also recommended that in the event of the Gas Company applying for such powers, the Corporation should take the matter into their own hands and obtain the necessary powers.

Statistics on the Use of Steam Engines for Electric Installations in Prussia.—The total number of steam engines employed in generating electricity in Prussia has increased during the last two years by 28·2 per cent. and their output by 39·6 per cent. At the beginning of 1891 the number of engines so employed was 1·59 per cent. of the total number in Prussia, and their capacity 2·68 per cent. of the total. At the beginning of the following year these numbers had been increased to 1·94 per cent. and 3·5 per cent. respectively.

Lightning.—During a severe thunderstorm which broke over Bristol on Friday afternoon last the flagstaff on Brandon Hill was struck by lightning. The pole, which was about 50ft. high, was surmounted by a vane. The discharge struck the vane, and followed the course of the rope used to hoist the flag, which was twisted round the pole, until it reached the oak supports—a large splinter of which, weighing nearly 56lbs., it drove a distance of more than 20 yards—the discharge charred the remainder of the support, and eventually reached the ground.

Derry.—On Tuesday evening last the Londonderry Corporation unanimously adopted a resolution deciding to light the entire city by arc lamps, at a cost not exceeding £12,500. The Chairman of the Lighting Committee said the system would be similar to that adopted in Dublin, except that each street would be lighted from two distinct circuits, so that the failure of the light was practically impossible. The Gas Company charged the Corporation £2,000 yearly for the present lamps, and this sum would not only pay the interest on the loan, but provide for a sinking fund and leave £200 yearly profit.

Electric Traction in Tasmania.—An electric tramway, on the overhead trolley system, is being erected at Hobart (Tasmania) by Messrs. Siemens Brothers and Co. The line, a single track one, about 8½ miles long, is on the 3½ft. gauge. The trolley wire is carried on insulators, suspended from wires stretched across the track from tubular iron poles, which also carry the feeder wires. The cars are intended to carry 48 passengers (24 inside and 24 outside), and each one is driven by two 18 H.P. motors. Three 150 H.P. Willans-Siemens sets are provided at the generating station. The voltage employed is 500.

An Electric Water Cart.—An original method of watering the streets of Albany, N.Y., is illustrated in a recent issue of the *Electrical World*. A huge iron tank filled with water, made in the form of a street car, in order that its appearance may be more ornamental, and that it may be less likely to frighten horses, is used. A water pipe connected to the front end of the car extends out over the street and scatters the water over a large area. The pipe has a swinging joint, so that it can be turned back parallel to the car. As the car can carry a large quantity of water, and move at a comparatively high speed, it should prove useful.

Terrestrial Magnetism.—M. Moureaux, of the Parc Saint-Maur Observatory, has completed for this year his observations in connection with the construction of a magnetic chart of France. During the Spring and Summer months M. Moureaux has taken observations in the central departments, Savoy, the Vosges, and the Jura. Up to date determinations of the declination, inclination, and total intensity have been made at 459 places in France in the same manner, with the same instruments and by the same observer. Except along the coast line, all France north of the 45th parallel has now been magnetically mapped out.

Forthcoming Books.—In addition to the works mentioned in our issue of September 23rd, the following are announced as in preparation:—"Domestic Electric Lighting, treated from the

Digitized by Google

Consumer's Standpoint," by E. C. de Segundo (H. Alabaster, Gatehouse, and Co.); "The Year Book of Science," edited by Prof. Bonney (Cassell and Co., Limited); "The Students' Chemistry," by R. L. Taylor (Sampson Low and Co., Limited); "Matriculation Chemistry," by Temple Orme (Lawrence and Bullen); "An Elementary Manual of Applied Mechanics," by Prof. A. Jamieson (Charles Griffin and Co.); and a new work on practical physics, by Prof. W. F. Barrett (Percival and Co.).

Atmospheric Electricity.—*La Lumière Electrique* announces that M. André, well known for his researches on atmospheric electricity, which have been published in these columns, has met with a serious balloon accident. On Wednesday, the 28th ult., M. André made an ascent in a balloon called the *Espérance* with an assistant and an æronaut, his object being to make electrical observations in mid air, for which purpose he shipped 200lb. weight of apparatus. The ascent took place in a high wind and with insufficient ballast. Half an hour afterwards, when about 25 miles from Lyons, it became necessary to descend. The car was dragged along the ground about two miles before it could be stopped, and M. André sustained considerable injury. He will, however, shortly resume work.

Worcester.—At a meeting of the Watch Committee on Saturday last the Town Clerk reported that the Severn Conservators would oppose the proposal to utilise water power at the Diglis Weir for the purposes of the electric light. A letter had been received offering to grant a lease for 99 years of the Powick Mills at £160 per annum, or to sell the building for £5,000, in either case keeping up the weir. A letter was considered from the Brush Company giving details as to the best mode of utilisation of the water at Powick Mills. The sub-committee were of opinion that the proposal to utilise the water power at Diglis should be abandoned, but that the suggestion for placing the generating station at Powick Mills was worth serious consideration, and the surveyor was directed to report on the power likely to be derived from the Teme, and as to the possibility of navigating the Teme up to the mills.

Societies' Meetings.—Meetings of the Institution of Mechanical Engineers will be held on Wednesday and Thursday, October 26th and 27th, at 25, Great George-street. The chair will be taken at 7:30 each evening by Dr. William Anderson, F.R.S. The following Papers will be read and discussed as far as time permits:—"Second Report of the Research Committee on the Value of the Steam Jacket," "Experiments on the Arrangement of the Surface of a Screw Propeller," by Mr. William George Walker.—The first ordinary meeting of the Second Session of the Institution of Mining and Metallurgy will take place on Wednesday next at 8 o'clock in the Lecture Theatre of the Geological Museum, Jermyn-street. After an address from the President, Mr. H. M. Becher's Paper on "Mining in the Malay Peninsula: a Field for Mechanical Appliances, Hydraulics, and Electrical Transmission of Power," and Lieutenant Walter Bassett's Paper on "Auriferous Iron Sands and the Methods of Extracting Gold Therefrom" will be discussed.

Manchester.—At the last meeting of the Town Council a member said that he wished to ask, on behalf of a number of ratepayers who had already completed their installations, when they might expect to have the electric light? Alderman Sir J. J. Harwood stated, in reply, that there were difficulties in the way that the gas committee had not at first anticipated. One was the erection of a large chimney, the completion of which could not be hurried without risk to the stability of the structure. Another was that a large room was being lined with glazed bricks, and there was delay in the supply of the material. He might add that everything was being done that could be done, and there was no unnecessary delay. The mains were being laid in the streets in a very efficient manner, and the wires would be ready by the time of the completion of the other works. Possibly that would be soon after Christmas; he was inclined to think it would be in March or April. In addition to the matters he had mentioned there were conflicting interests between contractors which kept back the work at the electric light station.

The City Lighting.—At the meeting of the Commissioners of Sewers on Tuesday last, the Streets Committee recommended that the sum of £1,211. 15s. 7d. should be paid to the City of London Electric Lighting Company for lighting certain of the public ways of the City up to June 30th last, without prejudice to the contracts and Provisional Orders. This was agreed to after some discussion. The Clerk then read a letter from the Electric Lighting Company, asking permission to use some of their pipes for telephone cables. It was moved that the communication should be referred to the Streets Committee. Mr. A. A. Wood, A.K.C., F.C.S., was of opinion that, although the letter might be referred to the consideration of a committee, the Court should emphatically express their objection to the way in which this work had been done. It was, to his mind, exceedingly unbecoming for the Company to lay pipes without the knowledge or consent of the Court. Mr. A. C. Morton, M.P., wished to know why the Company had not approached the Court before laying the tubes. An amendment was moved and seconded to the effect that the consideration of the matter should be adjourned pending the carrying out of the Company's contracts. Mr. Bridgman reminded the Court that the National Telephone Company made a similar application some time ago, but it was refused. He considered that the City of London Company had stolen a march upon the other company. Mr. Shaw, having referred to the action the Court took in the matter of overhead wires about twelve years ago, said if there had been any trickery, as had been suggested by some speakers, he would not defend those concerned, but he thought the Court should, if they were able, make the persons pay for the concessions they had availed themselves of. The amendment was finally voted upon, and rejected by a large majority.

Flexible Metallic Tubing.—In a Paper recently read before the Society of Arts, Mr. Gilbert R. Redgrave, Assoc. Inst. C.E., described an ingenious form of flexible metallic tubing evolved by M. E. Levavasseur, of Paris. Satisfactory specimens have been turned out of a spirally-wound tube, made of thin metal strips of a peculiarly corrugated section, in which perfectly tight joints have been secured by simple interlocking of the coils of metal, without packing of any kind. Tubing of this kind has been employed at the Naval Exhibition to carry steam at 150lb. pressure; it has also been supplied to a leading railway company to carry petroleum gas at 200lb. pressure, and it has been applied with success to the pumping of petroleum oil. Mr. Redgrave suggested that the tubing was applicable as an armoured sheathing for telegraph, telephone, electric light, and submarine cables (shore ends). Some details respecting the weight of the tubing were given. The $\frac{5}{16}$th inch tubing, at present the smallest size made, weighs 2½oz. per lineal foot, ½in. 4oz. per foot, ¾in. 8½oz. per foot, 1in. 11oz. per foot, 1½in. 17oz. per foot. The $\frac{5}{16}$th and ⅜th inch sizes have been tested up to 2,700lb. per square inch of hydraulic pressure, the ½in. diameter tubing has withstood 2,000lb. per square inch; the larger sizes carry a gradually decreasing pressure down to 1,500lb. per square inch for the 1in. tubing. In the discussion which followed the reading of the Paper, Mr. C. U. Gray doubted whether the tubing would be used for electrical purposes. The shore end of a submarine cable was subjected to very rough usage on a rocky shore; and if the tube got fouled by any rock or projection, it might open up the metal. To cover an ordinary cable with a tube of the kind seemed to him somewhat risky. Though the tube might be perfectly tight, it would be impossible with so many joints in a long length to prevent moisture, and gas, permeating into the cable and destroying the insulating material. Again, by bringing two metals together which had been subjected to a strain for some time, so that they were in a distinctly different molecular condition, an electrical action which would corrode and wear the joints might be set up. Mr. H. Edmunds said the ordinary stranded wire armour had the disadvantage that the strands being parallel there was an opportunity for anything to pierce in between the strands. Any hard solid metal, such as iron or copper, was not flexible, and lead was too soft; but this flexible tube seemed to afford a solution of the problem. He did not know that it would be particularly applicable for the shore ends of submarine cables unless further protected by wire strands; but if for wiring a building, it would be very serviceable.

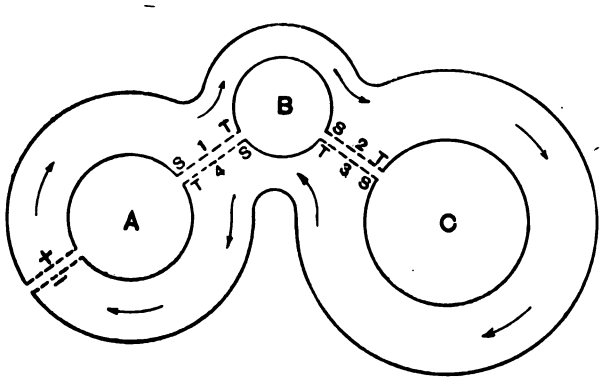
TO DRAW A MERCATOR CHART ON ONE SHEET, REPRESENTING THE WHOLE OF ANY COMPLETELY CONTINUOUS CLOSED SURFACE.

BY LORD KELVIN, P.R.S.

If a solid is not pierced by any perforation, its surface is called simply continuous, however complicated its shape may be. If a solid has one or more perforations or tunnels,* its whole bounding surface is called "complexly continuous;" duplexly when there is only one perforation; $(n+1)$-plexly when there are n perforations. The whole surface of a group of n anchor rings (or "toroids") cemented together in any relative positions is a convenient and easily understood type of an $(n+1)$-plexly continuous closed surface. Let the diagram represent a quadruplexly continuous closed surface made of very thin sheet metal, uniform as to thickness and homogeneous as to quality throughout. To prepare for making a mercator chart of it, cut it open between perforations C and B, B and A, A and outer space, in the manner indicated at $\frac{2}{3}$, $\frac{1}{4}$, and $\pm$. Apply infinitely conductive borders to the two lips separated by the cut at $\pm$, and apply the electrodes of a voltaic battery to these borders. By aid of movable electrodes of a voltmeter trace on the metallic surface a very large number $(n-1)$ of equidifferent equipotential closed curves between the + and − borders. Divide any one of these equipotentials† into parts each equal to the infinitesimal distance perpendicularly across it to the next equipotential on either side of it, and through



the divisional points draw curves cutting the equipotentials at right angles. These curves are the stream lines. They and the $(n+1)$ closed equipotentials (including the infinitely conductive borders) divide the whole surface into $n\,m$ infinitesimal squares, if m be the number of divisions which we found in in the equipotential. The arrows on the diagram show the general direction of the electric current in different parts of the complex circuit; each arrow representing it for the thin metal shell on either far or near side of the ideal section by the paper.

Considering carefully the stream lines in the neighbourhoods of the four open lips marked in order of the stream 1, 2, 3, 4, we see that for each of these lips there is one stream line which strikes it perpendicularly on one side and leaves it perpendicularly on the other, and which I call the flux-shed line (or for brevity the flux-shed), for the lip to which it belongs. The stream lines infinitely near to the flux-shed, on its two sides, pass infinitely close round the two sides of the lip and come in infinitely near to the continuation of the flux-shed on its two sides. Let F_1, F_2, F_3, F_4 (not shown on the diagram) be the points on the + terminal lip from which the flux-sheds of the lips 1, 2, 3, 4 proceed; and let G_1, G_2, G_3, G_4 be the points at which they fall on the − lip. Set S_1, T_1, S_2, T_2, &c., denote the points on the four lips at which they are struck and left by their flux-shed lines.

Let p_1, l_1, p_2, l_2, p_3, l_3, p_4, l_4, p_5 be the differences of potential from the + lip to S_1, from S_1 to T_1, T_1 to S_2, ... S_4 to T_4, and T_4 to the − lip. Measure these nine differences of potential. We are now ready to make the mercator chart. We might indeed have done so, without these elaborate considerations and measurements, simply by following the rule of my previous article; but the chart so obtained would have had infinite contraction at eight points, the points corresponding to S_1, T_1 ... S_4, T_4. This fault is avoided, and a finite chart, showing the whole surface on a finite scale in every part, is obtained, by the following process:—

Take a long cylindric tube of thin sheet metal, of the same thickness and conductivity as that of our original surface, and on any circle, H, round it mark four points, h_1, h_2, h_3, h_4, at consecutive distances along its circumference proportional repectively to the numbers of the m stream lines, which we find between F_1 and F_2, F_2 and F_3, F_3 and F_4, F_4 and F_1, on the + lip of our original surface. Through h_1, h_2, h_3, h_4 draw lines parallel to the axis of the cylinder.

Let now an electric current equal to the total current which we had from the + lip to the − lip through the original surface be maintained through our present cylinder by a voltaic battery with electrodes applied to places on the cylinder very far distant on the two sides of the circle H. Mark on the cylinder eight circles, K_1, K_2, ... K_8, at distances consecutively proportional to l_1, p_2, l_2, p_3, l_3, p_4, l_4, and absolutely such that l_1, p_1, &c., are equal to the differences of their potentials from one another in order. Bore four small holes in the metal between the circles K_1 and K_2, K_3 and K_4, K_5 and K_6, K_7 and K_8, on the parallel straight lines through h_1, h_2, h_3, h_4 respectively. Enlarge these holes and alter their positions, so that the altered stream lines through h_1, h_2, h_3, h_4 (these points, supposed fixed and very distant) shall still be their flux-sheds. While always maintaining this condition, enlarge the holes and alter their positions until the extreme differences of potential in their lips become l_1, l_2, l_3, l_4, and the differences of potential between the lips in succession become p_2, p_3, p_4. In thus continuously changing the holes we might change their shapes arbitrarily; but to fix our ideas we may suppose them to be always made circular. This makes the problem determinate, except the distance from the circle H of the hole nearest to it, which may be anything we please provided it is very large in proportion to the diameter of the cylinder.

The determinate problem thus proposed is clearly possible, and the solution is clearly unique. It is of a highly transcendental character, viewed as a problem for mathematical analysis; but an obvious method of "trial and error" gives its solution by aid of electric measurement, with quite a moderate amount of labour if moderate accuracy suffices.

When the holes have been finally adjusted to fulfil our conditions, draw, by aid of the voltmeter and movable electrodes, the equipotentials, for p_1 above the greatest potential of lip 1, and for p_5 below the least potential of lip 4; and between these equipotentials, which we shall call f and g, draw $n-1$ equidifferent equipotentials. Draw the stream lines making infinitesimal squares with these according to the rule given above in the present article. It will be found that the number of the stream lines is m, the same as on our original surface, and the whole number of infinitesimal squares on the cylinder between f and g is $m\,n$. Cut the cylinder through f and g; cut it open by any stream line from f to g; and open it out flat. We thus have a mercator chart bounded by four curves cutting one another at right angles and divided into $m\ n$ infinitesimal squares corresponding individually to the $m\,n$ squares into which we divided the original surface by our first electric process. In this chart there are four circular blanks corresponding to the lips 1, 2, 3, 4 of our diagram, and there is exact correspondence of their flux-sheds and neighbouring stream lines, and of the disturbances which they produce in the equipotentials, with the analogous features at the lips of the original surface as cut for our process. The solution of this geometrical problem was a necessity for the dynamical problem with which I have been occupied, and this is my excuse for

* A "hole" may mean a deep hollow, *not* through with two open ends. The word "tunnel" is inappropriate for the aperture of an anchor ring. Neither "hole" nor tunnel being unexceptionally available, I am compelled to use the longer word, "perforation."

† Two sentences of my previous article ("Generalisation of Mercator's Projection") in § 3, and in last paragraph but one are manifestly wrong, and must be corrected to agree with the rule given for dividing into infinitesimal squares, in the present text.

working it out; though it might be considered as devoid of nterest in itself.

Errata.—"Generalisation of Mercator's Projection Performed by Aid of Electrical Instruments." In the last sentence of the fourth paragraph of this article, which appeared on page 553 of our issue of September 23, *for* "three" *read* "two." For corrections in Section 3, and in last paragraph but one, see the present article.

PROPAGATION OF THE CURRENT IN A CABLE CONTAINING DISTRIBUTED STATIC CAPACITY AND SELF-INDUCTION.*

BY FREDERICK BEDELL, PH.D., AND ALBERT C. CREHORE, PH.D.

(*Concluded from page 621.*)

Circuits with no Self-Induction.

When the effect of self-induction is not considered in the cable, we may put $L=0$ in the current and potential equations (22) and (21), and reduce them to more simple forms, thus

$$e = E\epsilon^{\pm\sqrt{\frac{CR\omega}{2}}x}\sin\left\{\omega t \pm \sqrt{\frac{CR\omega}{2}}x\right\} \quad . \quad . \quad . \quad . \quad (23)$$

$$i = \mp E\sqrt{\frac{C\omega}{R}}\,\epsilon^{\pm\sqrt{\frac{CR\omega}{2}}x}\sin\left\{\omega t \pm \sqrt{\frac{CR\omega}{2}}x + 45^\circ\right\} \quad (24)$$

These results agree with those given by Mr. T. H. Blakesley in his book on "Alternating Currents of Electricity," page 60, Second Edition. They may be directly obtained from the differential equation ($8\frac{1}{2}$), and upon differentiation will be found to satisfy it.

Nature of the Wave Propagation.—Equation (23) shows that at any point of the conductor the potential varies harmonically with the time. At the origin, where $x=0$, the potential is always equal to $e=E\sin\omega t$, its maximum value being E; but, as we proceed from the origin, the potential becomes less, being equal to $E\epsilon^{-\sqrt{\frac{CR\omega}{2}}x}$ an expression which decreases as x increases. The double sign is retained in the exponent in the equation, since it represents two waves, one going in the positive and the other in the negative direction from the origin, which is the source of alternating potential. The maximum value of the potential at any point of the cable may be represented as in Fig. 2 by an ordinate to the logarithmic curve. Thus, $\overline{0A}$ represents the maximum value of the harmonically varying potential at the origin, and $\overline{BC}$ its maximum value at a distance x, from the origin. The distance $\overline{0B}$ is taken as that in which the logarithmic curve has decreased to $1/\epsilon$th of its original value, $\overline{0A}$. The distance $\overline{0D}$ is a quarter wave-length, and $\overline{0E}$ a half wave-length. It will be presently shown that the amplitude decreases to almost $\frac{1}{500}$th of its original value in one complete wave-length.

One of the most striking results shown by these formulæ is that the current always precedes the potential by one-eighth of a period, and this difference in phase is not altered by any change in the resistance or capacity of the cable.

Rate of Propagation.—Curve I. (Fig. 2) represents an instantaneous position of the potential wave travelling along the wire in each direction from the origin. The distance along the cable from one maximum potential to the next, or in other words, the length of one complete wave, may be found by equating to 2π the angle containing x in the equation. This gives

$$\sqrt{\frac{CR\omega}{2}}x = 2\pi,$$

or,

$$x=\lambda=2\pi\sqrt{\frac{2}{CR\omega}}=2\sqrt{\frac{\pi}{CRn}},$$

where λ denotes the length of one complete wave, and $n\left(=\frac{\omega}{2\pi}\right)$ the frequency of alternation.

The time of one complete period is represented by $T=\frac{1}{n}$, and in that time the wave advances a distance λ, equal to one wave-length. The rate at which the wave advances is found by dividing the wave-length by the time taken in advancing that distance; thus—

Rate of propagation $=\frac{\lambda}{T}=2\sqrt{\frac{n\pi}{CR}}=\sqrt{\frac{2\omega}{CR}}$. It is seen that the rate of propagation not only depends upon the character of the cable, but likewise varies as the square root of the frequency of alternation. A wave with a frequency of 400 will travel twice as fast as one with a frequency of 100 alternations per second.

Decreasing Amplitude.—The frequency not only affects the rate of propagation but it also has a marked influence upon the rate at which the amplitude of the waves decreases with

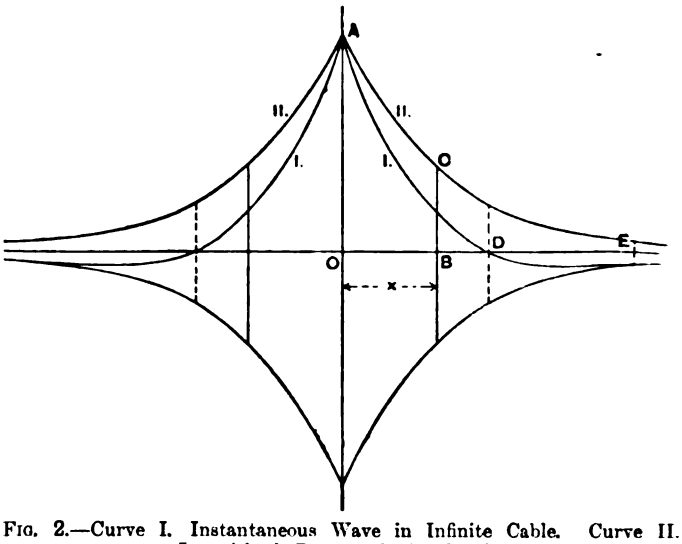

FIG. 2.—Curve I. Instantaneous Wave in Infinite Cable. Curve II. Logarithmic Decrease in Amplitude.

the distance. The distance, which we will call x, at which the amplitude of the wave will have $1/\epsilon$th of its original value, is the reciprocal of the coefficient of x in the exponent; thus—

$$x'=\sqrt{\frac{2}{CR\omega}}.$$

This distance, at which the wave decays to $1/\epsilon$th of its value at the origin, varies inversely as the square root of the frequency; this means that a wave with a frequency of 100 alternations per second can go twice as far as one with a frequency of 400 and experience the same decay in amplitude. Comparing this value of x' with that of a wave-length λ, we may write

$$x'=\frac{\lambda}{2\pi}.$$

The amplitude of a wave, therefore, decreases to $\frac{1}{\epsilon^{2\pi}}=0{\cdot}00187$ of its value in advancing a distance equal to one wave-length.

In order to find the time t^1, in which the amplitude decays to $1/\epsilon$th of its value, we must divide this distance, x^1, by the rate of propagation; thus:—

$$t^1=\frac{\frac{\lambda}{2\pi}}{\frac{\lambda}{T}}=\frac{T}{2\pi}=\frac{1}{\omega}.$$

We see that the time of decay varies inversely as the frequency; thus, a wave with a frequency of 400 alternations per second will decrease a certain amount in one-fourth the time a wave with a frequency of 100 is decreasing the same amount.

Circuits with Self-Induction.

It will be noticed that the introduction of self-induction into the cable in the manner before described does not materially alter the character of the wave propagation. This is evident from the equations (21) and (22). At every point of the conductor, the potential, or current, varies harmonically with the time and, as before, the amplitude of the wave decreases with a logarithmic decrement as it proceeds from the origin.

Phase Difference.—One effect of the self-induction is to change the angle of advance of the current ahead of the potential. Thus, angular difference is no longer a constant angle of 45°, as formerly, but is a function depending upon R L and ω, viz :—

$$\tan\theta = \sqrt{\frac{Im - L\omega}{Im + L\omega}} = \frac{P}{a}. \quad . \quad . \quad . \quad (25)$$

When $L = 0$, $\tan\theta = 1$, and $\theta = 45°$. As L increases from zero to infinity, the expression changes from unity to zero, and the angle θ, consequently from 45° to 0°. The effect of the self-induction is, therefore, to decrease the phase difference between the current and potential. This difference of phase also becomes less with an increase in the frequency.

Rate of Propagation.—The distance along the cable between two maxima is found by equating the angle containing x in equation (21) to π and solving for x, thus—

$$x = \lambda_1 = \frac{2\pi}{a} = \frac{2\pi\sqrt{2}}{\sqrt{C\omega}\sqrt{Im + L\omega}},$$

where λ denotes the wave-length. Subscripts are here used to denote circuits with self-induction. The time occupied in travelling this distance is $T = \frac{2\pi}{\omega}$; hence

$$\text{rate of propagation} = \frac{\lambda_1}{T} = \frac{\omega}{a} = \sqrt{\frac{2\omega}{C\{Im + L\omega\}}}.$$

It is noticed that the wave-length and the rate of propagation are each less than that found for circuits containing no self-induction. When $L = 0$ the expressions just found reduce to those previously given.

Another point to be noticed is that a change in frequency will have a greater effect in altering the wave-length, and not so great an effect in changing the rate of propagation as in the case of a circuit with no self-induction. Two waves of different periods will, therefore, go more slowly, but with less difference in their rates of propagation than with no self induction. As before, the wave of higher frequency will have the shorter wave-length and advance the faster.

Decreasing Amplitude.—As before, the amplitude of the harmonic wave has a logarithmic decrement, decreasing with the distance from the origin. The distance at which the amplitude has 1/ϵth of its original value is the coefficient of the exponent; thus,

$$x'_1 = \frac{1}{p} = \frac{\sqrt{\frac{2}{C\omega}}}{\sqrt{Im - L\omega}}.$$

This is larger on account of the self-induction. The substitution of $L = 0$ reduces it to the value of x^1 found before. An increase in frequency will cause this value to decrease, and the decay in a certain distance to increase; but the frequency has not so great an influence upon this decay as it has in a circuit with no self-induction.

Comparing with the values found for λ, and θ, we see that

$$x'_1 = \frac{\lambda_1}{2\pi\tan\theta}.$$

In order to find the time t'_1, in which the amplitude decays to 1/ϵth of its original value, we divide the distance x'_1, by the rate of propagation; thus—

$$t' = \frac{\frac{\lambda_1}{2\pi\tan\theta}}{\frac{\lambda_1}{T}} = \frac{T}{2\pi\tan\theta} = \frac{1}{\omega\tan\theta},$$

The self-induction causes $\tan\theta$ to have a value less than unity, thus increasing the time for a certain decay—that is, decreasing the rate. An increase in the frequency causes θ to become smaller. The exact effect upon the rate of decay caused by a variation in frequency in a circuit with self-induction depends upon the constants of the circuits. The wave of higher frequency will always decay the more rapidly, but with self-induction in the circuit there is less difference in the rates of decay of waves of different periods than there is in circuits without it.

Limitations of the Telephone.—The effects of distributed capacity in a conductor upon the wave propagation have been given, and the way in which these effects are altered by the introduction of self-induction or by a change in frequency. A consideration of the results with reference to telephone circuits is valuable, inasmuch as it is just such effects that cause the limitations to telephony. In all cases the waves of higher frequency travel the faster, and so the several harmonic components of a complex tone are constantly changing in their relative phases. The waves of higher frequency are likewise subject to the more rapid decay, and so when the several components are recombined the resultant tone may be materially altered from the original complex tone. These effects may be modified by the presence of self-induction, but in all cases they will be present to a certain extent, thus defining the limits of the use of the telephone.

Wave Propagation in Closed Circuits.

Let us consider that a dynamo giving an harmonic alternating E.M.F. is inserted at some point of a cable, such as that described, which forms a continuous closed circuit. There will be a forward wave of positive potential starting from one pole of the machine which will travel around and around the circuit continually, diminishing in amplitude until it finally vanishes. At the same time a backward wave of negative potential starts from the other pole of the machine, and travels around in the opposite direction until it, too, vanishes. The potential at any particular point of the circuit is thus the sum of the potentials due to all the positive and negative waves. Let l denote the length of the cable. When the first positive wave reaches a point at a distance x from the pole of the dynamo the potential due to the forward wave is—

$$e_{F_1} = E\,\epsilon^{-px}\sin(\omega t - a x).$$

where p and a have the values given in (19) and (20). When the wave has travelled completely around the circuit, and comes to this point a second time, its value is,

$$e_{F_2} = E\,\epsilon^{-px-pl}\sin(\omega t - a x - a l),$$

which may be obtained by substituting $x + l$ for x in the above. After going n times around the circuit it has become

$$e_{Fn} = E\,\epsilon^{-px-pln}\sin(\omega t - a x - a l n).$$

The resultant of all these forward waves at any one point may be written, therefore,

$$e_F = e + e_{F_2} + \ldots\ldots e_{F\infty} = E\epsilon^{-px}\sum_{n=0}^{n=\infty}\epsilon^{-pln}\sin(\omega t - a x - a l n) \quad . \quad (26)$$

When we consider all the backward waves, we may represent them by a similar expression in which E has the negative sign. When the first backward wave has travelled around the circuit so as to be a positive distance x, from the origin it has gone a distance $l - x$; this distance from the origin in a negative direction we will call x'. For the first backward wave we may then write

$$e_{B_1} = -E\,\epsilon^{-px'}\sin(\omega t - a x'),$$

and for the sum of all the backward waves,

$$e_B = -\epsilon^{-px'}\sum_{n=0}^{n=\infty}\epsilon^{=pln}\sin(\omega t - a x' - a l n) \quad . \quad . \quad (27)$$

These expressions (26) and (27) may be simplified, since we may put—

$$\sin(\omega t - a x - a l n) = \sin(\omega t - a x)\cos a l n - \cos(\omega t - a x) \times \sin a l n \quad . \quad . \quad . \quad . \quad . \quad . \quad (28)$$

Digitized by Google

Substituting (28) in (26), we have—

$$e_F = E\epsilon^{-px}\sin(\omega t - a x)\sum_{n=0}^{n=\infty}\epsilon^{-pln}\cos a l n - E\epsilon^{-px}\cos(\omega t - a x)\sum_{n=0}^{n=\infty}\epsilon^{-p n}\sin a l n \quad . \quad (29)$$

Similarly we may reduce (27) to (30)—

$$e_B = -E\epsilon^{-px'}\sin(\omega t - a x')\sum_{n=0}^{n=\infty}\epsilon^{-pln}\cos a l n + E\epsilon^{-px'}\cos(\omega t - a x')\sum_{n=0}^{n=\infty}\epsilon^{-pln}\sin a l n \quad . \quad (30)$$

The resultant potential at any point due to the forward and backward waves is the sum of E_F and E_B. Writing $l - x$ for x' in (30), and adding to (29) we obtain—

$$e = E\sum_{n=0}^{n=\infty}\epsilon^{-pln}\cos a l n\cdot\left\{\epsilon^{-px}\sin(\omega t - a x) - \epsilon^{+px-pl}\sin(\omega t + a x - a l)\right\} + E\sum_{n=0}^{n=\infty}\epsilon^{-pln}\sin a l n\cdot\left\{\epsilon^{+px-pl}\cos(\omega t + a x - a l) - \epsilon^{-px}\sin(\omega t - a x)\right\} \quad . \quad . \quad . \quad . \quad (31)$$

By means of the exponential values of the sine and cosine, the values of the two summations expressed in (31) are found to be

$$\sum_{n=0}^{n=\infty}\epsilon^{-pln}\sin a l n = \frac{\epsilon^{pl}\sin a l}{1 - 2\epsilon^{pl}\cos a l + \epsilon^{2pl}} \quad . \quad . \quad . \quad . \quad (32)$$

and

$$\sum_{n=0}^{n=\infty}\epsilon^{-pln}\cos a l n = \frac{\epsilon^{2pl} - \epsilon^{pl}\cos a l}{1 - 2\epsilon^{pl}\cos a l + \epsilon^{2pl}} \quad . \quad . \quad . \quad . \quad (33)$$

Let P O P (Fig. 3) represent the cable which is supposed to form a closed conductor, the ends at P being joined together. The maximum value of the potential at the positive pole of the dynamo is represented by $\overline{OA}$. As we go from A this decreases along the logarithmic curve A B C D E until it finally vanishes altogether. Similarly a backward wave coming from the negative pole decreases along the curve A' B' C' D' E'. At the point P, half-way between the poles of the dynamo, the middle point of the cable, it is evident that the potential remains continually zero; for at the point P the distance x is $\frac{l}{2}$, which value reduces equation (31) to zero.

If the length of the cable happens to be some multiple of a wave-length, the expression for the potential takes a simpler form. In this case each successive forward wave travels around the circuit in the same phase as the first, and all these forward waves may, therefore, be added together algebraically. The maximum resultant potential at any point will be the sum of the maxima of all the separate waves. In Fig. 3 e_{F1}, e_{F2}, represent successive forward, and e_{B1}, e_{B2} the corresponding backward waves. In the case where the cable is some multiple of a wave-length, the sum of the maxima of all the forward and of all the backward waves are represented by the dotted lines e_F and e_B respectively. The solid e, the sum of e_F and e_B, represents the resultant maximum potential along the conductor.

We have seen that the wave-length is $\lambda = \frac{2\pi}{a}$. When the cable is a multiple of a wave-length, $l = \kappa\lambda = \frac{2\pi\kappa}{a}$, and, therefore, $a l = 2\pi\kappa$. This value of $a l$ reduces equation (32) to zero, since $\sin 2\pi\kappa = 0$, and reduces (33) to

$$\frac{\epsilon^{p} - 1}{(1 - \epsilon^{pl})^2}.$$

These values cause the second term in (31) to vanish and the whole then becomes

$$e = E\frac{\epsilon^{px} - \epsilon^{pl-px}}{1 - \epsilon^{pl}}\sin(\omega t - a x),$$

which expresses the resultant potential, represented by the solid line e in Fig. 3, at any point of the cable, provided its length is some multiple of a wave length. When $x = 0$, this reduces to $e = E\sin a t$, the expression for the potential at the terminals of the dynamo. When $x = l/2$, the expression vanishes, showing that the potential is constantly zero at the middle point of the conductor. This last simplification was made possible by considering the length of the cable to be a multiple of the length of wave. Otherwise the algebraic addition of the maxima of the several waves would not be possible, since they would differ in phase. The construction of the resultant curves would not be so simple, but the nature of the results would not be materially modified. The phenomena in connection with the flow of current are similar, and are obtained in the same manner from the current equation.

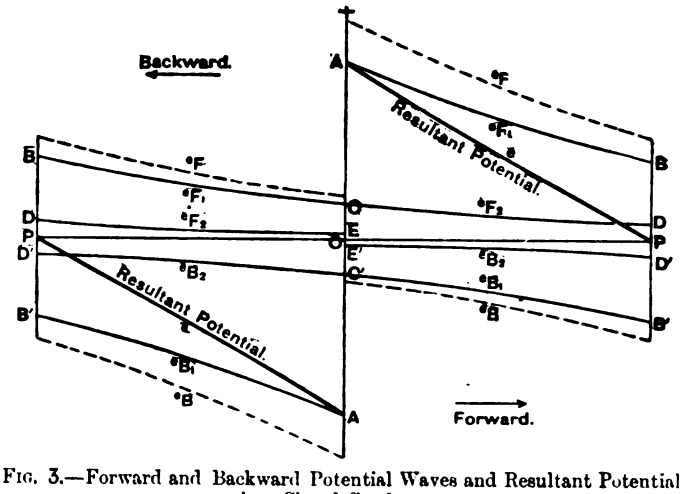

FIG. 3.—Forward and Backward Potential Waves and Resultant Potential in a Closed Conductor.

CABLE RELAYS.

BY WALTER JUDD.

I have been much interested in the recent communications to the electrical journals on the subject of cable relays. The cable relay is an instrument which has been, I suppose, the dream of cable managers and electricians for years, and one that has seriously occupied the minds of many of us. It may be interesting to those who have experimented in this direction if I shortly recount the experiments made in Hong Kong during the last five years.

The first idea that occurs to any experimenter is naturally a relay with fixed contacts; but, as Mr. Cuttriss says, the "sticktion" is fatal to success. In 1887 I endeavoured to vary the resistance in a local circuit by including in it a high resistance plunger dipping into a conducting solution, the resistance varying with the length of plunger out of the fluid somewhat as shown in Fig. 1, P being the plunger raised and lowered by the recorder

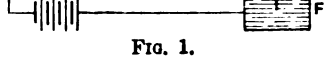

FIG. 1.

coil, I the local instrument, B battery, F the conducting fluid. I tried porous earthenware, carbon rods of high resistance, also compounds of Portland cement and plaster of Paris with plumbago and powdered carbon but found that a thin strip of ordinary paper gave the best results. I then tried thin elastic threads coated with powdered carbon or plumbago, obtaining the variation of resistance by the amount of extension produced by the movement of the recorder coil. Microphonic contacts of two carbon points were also tried but given up as impracticable, the range between perfect contact and infinity being too small and variable. All the above methods were tried in 1887 and 1888, but it was found that the principle sketched

Digitized by Google

above involved a current being always in the local instrument, the movement being obtained by increments and decrements of the current passing, rendering adjustment and fixed zero difficult to maintain. In 1889, in consequence of this difficulty, I adopted the bridge method, and from that date to this experiments have been carried out. I reverted to the plumbagoed elastic threads, but was unable to obtain good contacts, and therefore returned to the water resistance.

The experiments have all been carried out with an ordinary recorder, the aluminium siphon cradle being used as the pointer to be moved in the trough. At first the connections were thus (Fig. 2). The current from the battery all passed into the water trough T by the plunger or pointer P, and the current density, owing to the small surface, about 4 millimetres, caused immediate bubbling. To obviate this, the current was commuted into an alternating current, and redressed by another commutator in the galvanometer circuit, thus (Fig. 3).

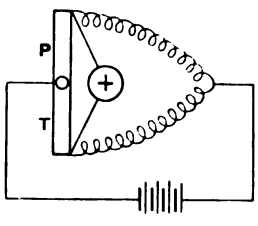

Fig. 2.

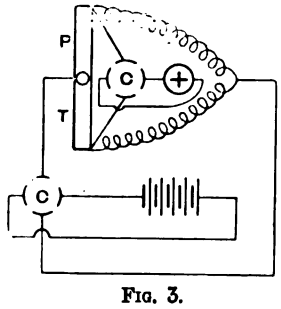

Fig. 3.

The two commutators CC were mounted, of course, on the same shaft, and it was found that, owing to the counter electromotive force set up in the water trough T, there was a slight lag and the commutator brushes had to be adjusted accordingly. The alternating current certainly diminished the trouble due to gas bubbling, but it was found still to occur when the current had passed for some considerable time, and by gathering round the pointer P the bubbles held it so fast as to almost destroy its movement. The next change was to make the connections so that the pointer only had to carry the current in the galvanometer circuit (Fig. 4). This effected a great improvement, and certainly reduced the bubbling.

We then dispensed with the commutator, and made a trough with large electrodes. In plan the trough was as in Fig. 5. A and B are circular holes, about $\frac{3}{4}$in. in diameter, in a slab of ebonite, joined by a narrow trough. A and B are lined with lead, and connected to suitable terminals. The whole system

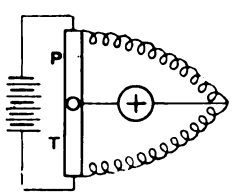

Fig. 4.

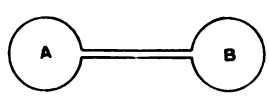

Fig. 5.

is then filled with liquid, and thus forms two arms of a bridge. With a considerable direct current we found that the bubbling became apparent after several hours, and evidently either larger electrodes or some depolarising compound was required. This it is difficult to use without at the same time making the liquid too conducting.

Matters were in this stage when we heard of Mr. Cuttriss's charming plan of spiral carbons (*The Electrician*, June 10, p. 147). If this works, then most undoubtedly in my opinion it is the best. Electrolytes are always variable, and they also evaporate, while carbon, once adjusted, should remain very fairly constant. I congratulate Mr. Cuttriss on his ingenious device, and trust that now attention is called to the subject the cable relay will soon be a *fait accompli*. The double differential system proposed by Mr. Raymond Barker in your contemporary, the *Electrical Review*, can easily be applied to the carbon spring method, and will, of course, make it more sensitive.

Now, one word as to its use when perfected. I think that it is hopeless to relay from one cable to another unless the cables are very short. For long cables I do not believe in the possibility of obtaining impulses sufficiently clear and distinct to operate any dead beat relay, which would be required to actuate signalling levers. If it could be done, the apparatus would be so delicate and complicated that it could never be left to itself, and if an experienced man is to be in attendance, it is far better to let him be the translator, as in Mr. Smith's human relay method. I have all along looked to a relay as a means of doing away with the siphon and the friction against the paper, which takes place at every vibration, and so obtaining a sharper and more defined movement reproducible upon a simpler and less sensitive local instrument. Any one who will watch the movement of the siphon cradle when the siphon is off cannot fail to see the gain in definition. This applies only, or principally, to long cables, and I imagine that a gain in speed of 10 to 20 per cent. can be realised by a good relay—an enormous advantage in every way. In common with all who are interested in cables, I wish every success to the ingenious inventors who have brought this much desired improvement within the sphere of practical teletics.

A DIFFERENTIAL VOLTMETER.

For the purpose of testing the drop in a Hedgehog transformer, run from a gas engine or unsteady steam engine, Mr. Swinburne has designed an ingenious instrument, which enables accurate measurements to be made in spite of considerable variations of speed in the dynamo. We reproduce a

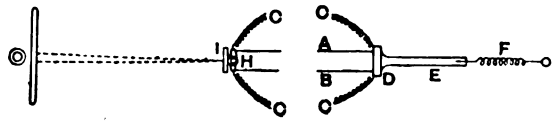

diagram of the instrument from *Industries*. The object is to measure a small change of voltage. If one voltmeter only were used, it would follow all the fluctuations of speed and accurate readings would be out of the question; a differential Cardew voltmeter is therefore employed. This is alluded to in the article, as is the fashion amongst some writers, as a hot-wire voltmeter.

To obtain a standard, the primary coil of a closed circuit transformer was used as resistance, and this was tapped at two places, between which there was a difference of potential of 100 volts at the average speed of the engine, but owing to fluctuations this voltage would not be steady. These volts were measured by one of the wires of the differential voltmeter, the other being used for measuring the voltage of the Hedgehog under test. When the speed, for example, dropped a little, both parts of the differential voltmeter would be equally affected, but any difference in the voltage of the two circuits would be indicated by a steady deflection of the instrument. In the diagram A and B are the two hot wires, and these are connected at one end to the block D of ivory, having a long tail-piece E, kept taut by a spiral spring F. The other ends of these wires are attached to a short lever, H, which carries a mirror, I; flexible connections are provided between the wires A and B and the terminals C. The instrument is said to be very sensitive, reading to within a small fraction of 1 per cent. The drop of the transformer was thus accurately determined, although the speed of the engine was varying considerably. In view of the great difficulty of getting accurate readings when testing dynamos or other electrical apparatus driven from gas engines or other unsteady sources of power, Mr. Swinburne's differential arrangement seems to offer considerable advantages.

Electric Tramway in the Tyrol.—It is intended to build an electric tramway between Riva and Pinzolo. The line will be 26 miles in length.

SPECIAL NOTICE.

With "THE ELECTRICIAN" for October 28th will be issued a Supplement STEEL-PLATE PORTRAIT of the late CYRUS W. FIELD, Pioneer of Ocean Telegraphy.

The Portrait is a very striking one, and is engraved in the best style. A few copies will be printed on India Paper, and will be forwarded post free on roller, price 3s. 2d. per copy; ordinary copies of the Portrait, post free, 1s. 2d., or framed in Black Pillar or Brown Ornamental Frame, price 4s. 6d., carriage extra.

Prospectus of "THE ELECTRICIAN" *Series of Fine Steel-Plate Portraits (13 in all) post free on request.*

OCTOBER, 1878.

We estimate past history in decimals. Once, by the decade and lustrum, and now, by centuries, or by generations the third of a century. But in measuring the history which is yet to come, the favourite unit is seven. The perfect number is chosen by the surveyor who fixes his inaccessible points out into the dim future. Leases are commonly made out in seven, fourteen or twenty-one years, and penal servitude is meted out in the same units. Seven years is the limit of a Parliament. Twenty-one years was the duration of the first stage of existence for electric supply companies, proposed by Mr. CHAMBERLAIN, and afterwards extended by no septennial increment, but by the factor 2. In the Statute of Monopolies a term of twenty-one years is mentioned, but for the future it was enacted that the duration of a patent should be fourteen years. Glancing back fourteen years takes us, then, to the genesis of those patents which are now expiring, and probably no period in the history of electric lighting showed greater inventive activity than October, 1878. The only electrical patent of importance in the early part of that year was dated May 18, No. 2,003, Brush's great compound winding patent; but several others of interest are to be found, *e.g.*, Wallace's arc lamp with flat carbons, No. 240, Miss Hosmer's magnetic engine Nos. 311, 2,930 and 3,676, and La Cour's phonic wheel, No. 1,988. Among the numerous arc lamp patents we find Werdermann, No. 2,477, which is worthy of mention, since an arrangement of lamps in parallel circuit with two-way switches and equivalent resistances is described; a curious half-way stage between true parallel running and the equivalent resistance system of switching on series circuits. The

Digitized by Google

negative main was doubled back upon itself, so that "the electric currents for all the lamps or lights will have to flow the same distance." In August we find the Obach galvanometer (No. 3,317), with inclined coil, and in the following month De Meritens (No. 3,658) patented his dynamo.

The series of electric lighting patents of October begins with No. 3,912 on the 4th, by W. S. Wilson, who proposed to improve the arc by "gas or vapour of sufficient conducting power, such as a metallic vapour or hydrocarbon," an idea which has been often re-invented. On the 9th M. Radcliffe Ward patented some doubtful improvements (No. 3,976) on the Gramme dynamo; on the same day, No. 3,985, Sir H. W. Tyler proposed the use of platinum or other gaseous liquid or solid materials to give a light, together with other sundry devices. The same day is memorable for No. 3,988, the Lane-Fox patent, which we need not describe. The problem of "the subdivision of the electric light" was in the air, and Lane-Fox's patent contained the first clear enunciation and practical solution of it, by constant voltage, low resistance mains, and high resistance lamps. On the same day, October 9, 1878, J. Clark filed an application, No. 3,991, for "adapting the electric light to domestic and other purposes." In this invention a bath of mercury was to be placed at the end of the main conductor, and from this a number of finer conductors, all preferably of uniform length and resistance, led to the lamps. Clark's first claim was for "the method of subdividing a strong current of electricity or magneto-electricity by passing it through a number of secondary wires of equal length and thickness, substantially as described." The lamps were made by enclosing finely-powdered charcoal in glass tubes, which were then surrounded by a larger globe. Here was parallel running from an "omnibus bar." On the next day S. Marcus, of Vienna, communicated his invention for "an incandescence lamp," but it seems to have been of the Werdermann type, a weighted carbon rod being pressed against the edge of a carbon disc. On the 11th came the first of a remarkable series of inventions for "division." No less than five times in the course of this month the same device, with trifling variations, was patented. J. Munro led the way with No. 4,016. A rapidly-revolving shaft was connected to one terminal of the generator, and the ends of all the lamp circuits "say a hundred, less or more," were arranged radially round this shaft. A brush contact swept round, making contact with every lamp in each revolution. The successive contacts were to be made so rapidly, 600 to 1,800 per minute, that no flicker would be perceptible. On the 5th of November, an appropriate day for fireworks, three more current dividers of exactly the same kind were patented. Several of the inventors seem to have imagined that so long as the lamp had not time to go out between the intervals of contact, so long, in fact, as it continued to burn while robbed of its current, there was an enormous economy. The Delany multiplex telegraph, invented long afterwards, is a singular application, in a correct and most useful form, of the principle of multiple contacts.

Returning to October, 1878, we find, after some miscellaneous inventions, Lane-Fox's second electric lighting patent, No. 4,043, in which he suggests enamelled wire for boiling water and heating, and switches for coupling secondary batteries. Passing over four more electric light patents we find two inventions of I. L. Pulvermacher, the first (No. 4,079) relates to a reflector of glass thinly coated with platinum, thus combining a translucent shade with a tolerable reflector. The efficiency of the arrangement was probably little better than opal glass, though it seemed attractive at the time. F. H. Varley followed with No. 4,100, in which carbon powder was fed on to the lower electrode of an arc lamp by a clockwork. On the next day (16th) came the third rotary divider, and an arc lamp (No. 4,116) of Prof. G. Forbes, in which the light was to be exhibited in flashes of extremely short duration by vibratory carbons points, or by a number of carbons on a rapidly revolving wheel. "At the present time," says the inventor in the specification, "the great obstacle to the progress of electric lighting is the difficulty in establishing any considerable number of lights in connection with one electric circuit." He admits that the intensity of the light "increases and diminishes with the number of flashes per second." Disregarding four patents, we come to unipolar dynamo, No. 4,206, by R. Paget Higgs, who was probably unaware that E. W. Siemens and F. H. von Alteneck had communicated a similar invention (No. 3,131) less than seven weeks earlier. No. 4,208 described an arc lamp by C. W. Siemens, and in No. 4,212 Sir Charles Bright patented the lighting of vacuum tubes by the secondary coils of an induction apparatus situated at each point where the light was required, the primary coils were to be coupled up to a main conductor common to them all. May this be freely interpreted as allowing a transformer to each house?

The next day, October 23rd, in No. 4,226, Edison's invention for "developing electric currents and lighting by electricity" was securely lodged at the Patent Office. His last British patent had been for an electric pen almost exactly three years before. Certain features of this invention burst upon an astonished world as the first of a long series of electric lighting marvels, whilst certain other features have been discreetly buried in oblivion. The platinum spiral with its automatic cut-out was talked about until hundreds of people believed and believe to this day that Edison "invented the electric light." The electrolytic meter still survives, but what shall we say of that magneto-electric-generator consisting of a huge tuning-fork carrying electro-magnets which were to wave in front of fixed magnets, the vibrations being maintained by a small air, gas, or steam engine, suitably connected to the end of each arm of the fork? "It has been known," he states in the specification, "that vibratory bodies such as a tuning-fork or reed can be kept in vibration by the exercise of but little power." Out of 68 illustrations, the first depicts the "very large tuning-fork," and the rest show different forms of the lamp and cut-out. It is easy to laugh at this monstrosity, but it stands as an interesting record of the mechanical and electrical measure of a man who was so soon afterwards to do so much. Edison took only one other British patent in 1878 for electric light, and three in 1879, but nine were applied for in the following year, while during 1881 they poured in at the rate of one a fortnight. Two days later, on October 25th, J. E. Stokes, of Upton Manor, Essex, described a light-emitting spiral surrounding a rod of metal, which by its expansion actuated a lever and cut the lamp out, exactly as detailed by Edison. The illustrations show even the same pattern of terminal post, a tapering pillar; and the coiled filament is precisely the same, and like Edison's is shown with ten turns, the loop at the end pointing upwards to the right. Seven more electric lighting patents bring us to No. 4,316 of Berthoud and Borel for their well-known lead-covered wire; and on the last day of the month we find an incandescence lamp by S. F. Van Choats, of New York (No. 4,388), in which the ribbon or spiral is formed of asbestos, mica, platinum, or carbon, or any combination of these—a near approach to a carbon lamp. Edison, however, was still busy with platinum until as late as June of the following year, and his carbon spiral was not patented until No. 4,576, on November 10, 1879. The nearest approach to

Digitized by Google

it in 4,226 of 1878 was Fig. 7, which represents "a light-giving body formed of platina or similar wire, around which carbon is made to adhere by pressure." SWAN, on the other hand, who had long before this experimented with carbon filaments, did not apply for a patent until January 2, 1880. Our list ends with the fifth rotary current divider by T. A. BELL, of Liverpool, and a patent for heating by means of platinum or other wires.

Turning to our own columns, we find a short note of four lines, immediately before the leading article in our issue of October 5, 1878. It is there recorded that LANE-FOX's lamp-lighting in Pall Mall had been in successful operation for the last fortnight. After a leader on telegraphic education comes an article by Prof. AYRTON on "Single and Double Current Duplex Translation," dated from the Scientific Club, Savile-row. Fads were rife then as now, and Mr. DESMOND FITZ-GERALD contributes a long letter on British Association Units, advocating megafranks, franklinads, &c., and speaking of vebers and microjoulads. Reports of meetings of three Gas Companies are to be found at the end of this issue; the advent of electric light, meaning, of course, arc and Jablochkoff lamps, is eagerly and shrewdly discussed. Our next number, dated October 12th, contains an article by Mr. OLIVER HEAVISIDE on "The Resistance of Telegraphic Electromagnets"; EDISON's carbon rheostat; an article by Prof. OLIVER LODGE on Dr. GUTHRIE's electrolytic experiments; and an extract from the *New York Sun* announcing EDISON's marvellous discovery. The issue ends with four columns of gas companies' meetings, from which we are greatly tempted to make some interesting extracts. Our leading article on October 19, 1878, discusses "The Scare among the Gas Companies." The last number of *The Electrician* in this month is full of electric lighting. "Mr. Fox's" letter to *The Times* on the use of condensers for distributing and dividing the current is commented upon. An illustrated description of the Weston dynamo is given. A Paper by Profs. AYRTON and PERRY, dated April, 1878, from the Imperial College of Engineering, Japan, on "The Resistance of the Arc of the Electric Light," is reproduced from "the new *Journal* of the Society of Telegraph Engineers." This is followed by a further gushing account of EDISON's rash promises to the *New York Herald*. The leading article contains surmises on "The Nature of EDISON's Invention," and explains how "carbon has been universally adopted as the wick, so to say, of the lamp;" and this produced "an unsteady and flickering light. This variation in resistance is also the chief cause of failure of attempts to subdivide the electric light. . . . Mr. EDISON surmounts all these difficulties by avoiding them. He embeds the ends of the conducting wires into a broad flat cake of some substance that is unattacked by the atmosphere when raised to incandescence by the passage of the current across it. What this substance is Mr. EDISON has not yet told us." At the end of this number is a report on the electric light, submitted to the Metropolitan Board of Works, and a report of the discussion on the lighting of the Embankment and Waterloo-bridge by Jablochkoff lamps.

Although we have discussed at unusual length the electrical patents which came into existence just fourteen years ago, when as yet domestic electric lighting was in the clouds, we do not claim that during October, 1878, an extraordinary number were applied for. It is the importance of several that we have enumerated, and the evident tendency even of the worthless ones towards useful ends, the awakening of many to the need for dividing the current, and the inception of the glow lamp, that stamp this month as a notable epoch in the history of electric lighting.

REVIEWS.

Lightning Conductors and Lightning Guards. By OLIVER J. LODGE, D.Sc., F.R.S., LL.D., M.I.E.E. (London: Whittaker and Co.)

Five years ago lightning conductors were not a topic to conjure with. The exact nature of the "thunderbolt" and the best shape for a lightning rod and its terminals had, it is true, formerly excited the scientific curiosity of a Franklin and aroused even a Faraday and a Snow Harris out of their habitual equanimity. But at the beginning of 1888 the subject of lightning conductors was apparently as exhausted as an extinct volcano. Everything had been reduced to regular routine; given high conductivity, continuity and a good earth and something approximating perfect protection followed; at least, so said all the authorities. Iron indeed was preferred by some to copper, but on purely mechanical and commercial grounds. Moreover, the "protected area" had not as yet become quite crystallised. Some believed in Mr. Preece's "special cone" which had a radius at the ground equal to the height of the rod, with concave sides marked out in section by an arc of 90 deg. described from a point on either side at the level of the top of the rod and distant from it by its own length. Others inclined to Melsens' ordinary cone, which had a base radius equal to only half its height. Such was the orthodox faith up to the time of Dr. Lodge's Mann Lectures, delivered before the Socicty of Arts on March 10 and 17, 1888. It was an instructive instance both of the dead weight of *ex cathedrâ* utterances even in the realm of science where in theory everyone is presumed to do the major position of his thinking for himself, and of the indifference with which fields of investigation presumably worked out are so frequently regarded.

It was with a lively recollection of the brilliant manner in which Dr. Lodge revivified the whole subject and at a single stroke landed us in the midst of theoretical and practical considerations of the highest import, that we turned over the five hundred and odd pages of his book, hoping to find therein not a mere miscellaneous reprint of articles, lectures, letters, reports, and experiments, but a comprehensive and comprehensible treatise which should at once be a contribution to science and to literature. But few men are gifted at once with a facile pen and the scientific spirit, and it is therefore a cause for regret that when such a combination does exist, an opportunity should be lost of making science popular by rendering it palatable. To those, however, who desire to have Dr. Lodge's collected papers on lightning conductors in a handy form, the present compilation will no doubt be welcome.

The Gas, Water, and Electric Lighting Companies' Directory, Gas Works Statistics, Water Works Statistics. Edited by CHARLES W. HASTINGS. (London: Hazell, Watson, and Viney.)

This is a well-printed publication of moderate dimensions, about which it is easy to find one's way, considerations too frequently overlooked in books of reference. Section IX., which is devoted to electric light undertakings, is marred by several sins of commission and omission, of which we give a few specimens. Unfortunate Barnet, although it has long since "gone back to gas," is the first name that meets the eye, and the arc lights which at the present moment nightly illumine Fleet-street notwithstanding, the western district of the City is still returned as unallotted to any company. Again, the Deptford *district* is credited with 40,000 lights and the Grosvenor Gallery with none. On the other hand, while small fry like Larne and Carlow are duly recorded, there is no mention of Dublin. Cardiff is down as still being in the hands of the Brush Company, and the column in which is recorded the number of lamps supplied suffers in many instances from a retardation of phase of about a twelvemonth. The items of information given are indeed just those wanted by business men, but the Editor must not forget that electric lighting is an advancing industry, and that what was possibly correct in June, 1891, is not so in June, 1892.

The Phonograph and how to Construct it. By W. GILLET. (London: E. and F. N. Spon, 1892.)

This book is devoted to one of those examples of useless labour upon which so many amateurs, who have a knowledge

Digitized by Google

of the use of tools and leisure for mechanical construction, waste their time and skill. It is a pity that the perseverance and ingenuity of such triflers cannot be "directed for the use and convenience of man," instead of being expended on toys of this kind. In making a "tinfoil phonograph" it is directed that the thread on the shaft should be cut with ordinary gas thread, by stocks and dies, for it is a point of honour with a certain class of amateurs to do all the work at home, whether proper tools are available or no. Out of 84 pages, less than eight are devoted to the construction of an electric motor to drive the phonograph. The wax cylinders, as described, take "nearly half-a-pound of wax" each.

GEARING.

BY E. TREMLETT CARTER.

(*Continued from page 588.*)

Worm Gear.

This is by far the best form of speed reduction gear for traction motor work, and even for another work it possesses merits which are not found in any other form. The first to apply it to electric traction was Mr. Reckenzaun, who has always found it a most efficient and reliable gear, and has used it in all his subsequent traction motor designs. Another authority, Mr. Holroyd Smith, after trying worm gear, has been loud in its praise, and has replaced every former gear with this particular kind. The writer has been led to make these remarks thus early in his account of worm gear in the hope

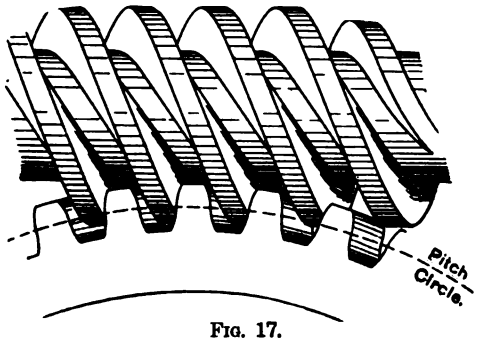

FIG. 17.

that the spice of the remarks may neutralise any prejudice against the poor worm which may have been lodged in the readers' minds from the too credulous perusal of theoretical textbooks, a prejudice which might otherwise have led them to pass on without reading his article. He hopes to show that the textbooks are misleading in this matter, and that the down-trodden worm is not as black as it is painted.

A glance at Fig. 17 will enable one to see the construction of single-thread worm gear. The gear consists in a driving spindle, on which a screw or thread is formed, and a spur wheel keyed to a driven spindle at right angles to the driving spindle. The teeth of the spur or worm wheel engage between the turns of the thread or worm, and as the latter turns on its axis the teeth are urged along in the direction of the worm axis, and the wheel is turned. In the single-thread gear, which is illustrated, each revolution of the worm spindle causes the engaged tooth to advance a distance equal to the space between the centres of two consecutive teeth, measured on a certain line called the pitch circle. This linear advance is called the pitch of the teeth, and it is evident that in single-thread worms it is equal to the pitch of the threads. The velocity ratio of single-thread gear is, therefore, equal to the number of teeth on the worm wheel. Thus, if there are 20 teeth on the worm wheel, a motor spindle turning at 600 revolutions per minute would cause the worm wheel to turn at 30 revolutions per minute. This high velocity ratio, however, could only be obtained at the sacrifice of a high efficiency, and where a lower ratio might be taken, if efficient working could thereby be secured, more than one thread is formed on the worm spindle. Double or treble-worm gear consists in two or three parallel threads placed on the spindle and gearing into the same worm wheel. In the former each thread misses one tooth, and in the latter it misses two teeth, as it coils round the spindle. It will be seen that in the double thread each revolution of the worm spindle causes the worm wheel to advance by the distance of two, and in treble-thread three, teeth of the worm wheel. In the latter the linear pitch of the thread is equal to three times, and in the former twice, the pitch of the teeth. The velocity ratio is then equal to the ratio of the number of teeth on the worm wheel to the number of threads on the worm.

In discussing this form of gear it will be very convenient to consider the threads unwrapped from the spindle and opened out to an inclined plane. In Fig. 18 a single turn of one thread has been thus unwrapped. A C is the circumference of the spindle at the pitch line, A B is the linear pitch of the thread, and B C is the length of one turn of the thread. The angle θ is the inclination of the axis of the worm to the plane of the thread; r is the radius of the spindle at the pitch line; t is the number of threads; p is the pitch of the *teeth*; and μ is the coefficient of friction between the thread and tooth engaged. The thread is driving the tooth, and is exerting an effort E in the direction shown. This force overcomes a resistance R, due to the driven tooth, and also balances a side-thrust T on the worm-wheel. This thrust and the resistance R combine to produce a normal thrust P on the face of the thread. The

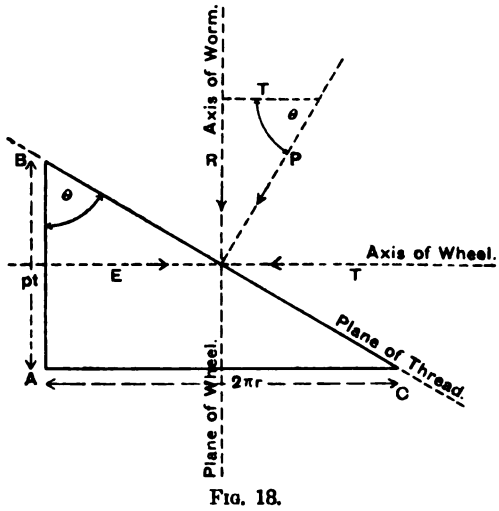

FIG. 18.

relationship between these forces is shown by the triangle of equilibrium. In one revolution of the worm spindle the effort E acts through the distance A C, so that the energy exerted is,

$$2 . \pi . r . E \quad . \quad . \quad \text{(energy exerted)}.$$

In the same time the force of resistance is overcome through the distance A B, so that the useful work done is

$$F . p . t \quad . \quad . \quad . \quad . \quad \text{(useful work)},$$

whence the efficiency is

$$\eta = \frac{F . p . t}{2 \pi r E}.$$

The energy wasted in overcoming friction is equal to the product of P into the coefficient of friction multiplied by the distance B C, and is also equal to the difference between the energy exerted and the useful work done. Whence

$$F . p . t = 2 \pi r . E - \mu . P . \left(\frac{2 \pi r}{\sin \theta}\right),$$

and

$$P = \frac{F}{\sin \theta};$$

whence

$$F . p . t = 2 \pi r E - \frac{2 \pi r . \mu . F}{\sin^2 \theta}.$$

Supplying the algebraic value of $\sin^2 \theta$,

$$F . p . t = 2 \pi r . E - \frac{\mu F \{(2 \pi r)^2 + (p t)^2\}}{2 \pi r}.$$

Dividing by the expression for the energy exerted we get

$$\eta = 1 - \frac{\mu F}{E} - \frac{\mu F}{E} . \left(\frac{p t}{2 \pi r}\right)^2.$$

Digitized by Google

Whence, $$\eta = 1 - \mu\eta\left(\frac{2\pi r}{pt} + \frac{pt}{2\pi r}\right);$$

or, the efficiency of the gearing is

$$\eta = \frac{1}{1 + \mu\left(\frac{2\pi r}{pt} + \frac{pt}{2\pi r}\right)}.$$

Calling k the ratio of r to p, this becomes

$$\eta = \frac{1}{1 + \mu\left(\frac{2\pi k}{t} + \frac{t}{2\pi k}\right)};$$

or, supplying the trigonometrical values, we obtain another interesting, though not so convenient form,

$$\eta = \frac{1}{1 + \left(\frac{\mu}{\sin\theta \cdot \cos\theta}\right)}.$$

This last expression shows by inspection that the efficiency has a maximum value at a particular angle of thread, viz., 45deg. And the previous expression indicates that the efficiency of any particular design is independent of the actual dimensions of that design, except in so far as the size affects the value of the coefficient of friction. If this latter is constant, a small worm gear may be as efficient as a large one.

The conditions which secure a high efficiency are as follows:—The coefficient of friction should be small, the ratio k should be small, and the angle θ should be as near 45deg. as possible. It is not found to be practicable to make the ratio k less than 1·5, so that even with treble thread gear the angle is very much larger than the most efficient value. To obtain a pitch angle of 45deg. with this value of k it would be necessary to have 9 or 10 separate threads, a number which would be prohibitive except in the case of very large gear, and which has never been tried. The following table gives the relation between the values of k or t and θ or η, for worm gear having a coefficient of friction of 0·05. This value of μ has been taken as being an average figure where there is good lubrication, but it is probable that in the best instances of worm gear the friction has been much less than this. It will be seen how a low value for k and a high value for t are conducive to efficient running. Attention is particularly called to the high efficiencies in the multiple worm gear where k is small; figures which, derived as they are from pure theory, will help to settle the dispute about the inefficiency of worm gear. This table has been prepared especially for this series of Papers.

Table *giving the Efficiency and Pitch Angle (in degrees) for Single and Multiple Worm Gear* ($\mu = 0{\cdot}05$).

Number of threads.	Values of k.							
	1·5		2·0		2·5		3·0	
	θ	η	θ	η	θ	η	θ	η
1	84	66	85·5	61	86·4	56	87	50
2	78	80	81	76	82·5	70	84	66
3	72	85	76·5	82	79	79	81	76
4	67	88	72	86	76	82	78	80
5	62	90	68	87	72	85	75	83
6	57	90	65	88	69	87	72	85
7	54	91	61	89	66	88	70	87
8	50	91	58	90	63	89	67	88
9	46	92	55	91	60	90	65	89

It is sometimes desirable that the worm wheel should be able to drive the worm, and sometimes equally desirable that it should *not* be able to do so. In traction work, where an electromotor on the worm spindle drives a worm wheel on the car axle, it is necessary that when the current is switched off the momentum of the car should be able to drive the gear by the pressure of the teeth on the worm thread. For, if this provision were not made in designing the gear, the momentum of the car, being unable to drive the gear, would strip the teeth from the wheel. On the other hand, in cranes, hoists and elevators driven from an electromotor by worm gear, it is as necessary that the raised weight should *not* be able to turn the gear. For, if an elevator cage could drive the worm when the current was switched off, a serious element of danger would be introduced in the liability of the cage to fall when it was intended to be at rest. In such cases it is necessary that the gear should positively lock itself against reverse motion. By increasing the angle θ we may make the gear pass from a condition in which running back is impossible to one in which the wheel will drive the worm very easily. If θ is equal to or less than the limiting angle of friction for constrained motion, slipping cannot occur. This is the case when

$$\mu \geqq \cos\theta . \sin\theta.$$

Single thread gear of small pitch will, therefore, be used in cranes and hoists, and double or treble threads in gear for traction.

In order to eliminate the losses due to friction between the threads and teeth abundant lubrication is necessary. Mr. Reckenzaun and others have placed the entire gear in an oil bath, and the arrangement employed by Mr. Reckenzaun, who was the first to employ oil baths for electric traction work, is shown in Fig. 19. This consists in a sheet iron vessel completely enveloping the worm and wheel, through which the spindles pass by means of tightly fitting glands. The vessel is partly filled with oil, and the worm wheel carries this oil to

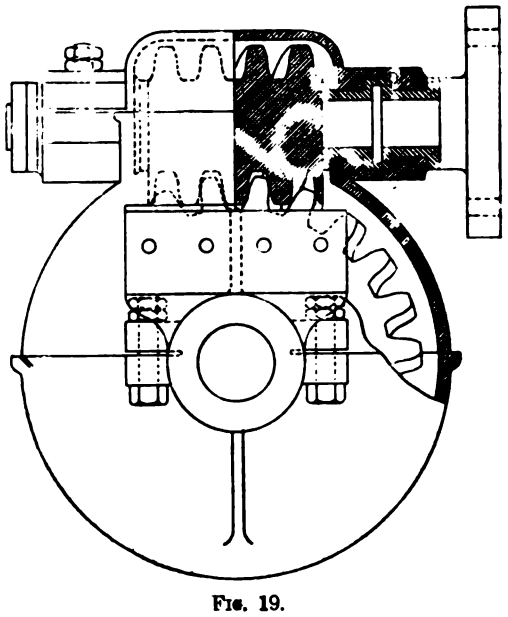

Fig. 19.

every moving part of the machinery. In addition to supplying the gear with almost perfect lubrication, this arrangement protects it from dust and mud. The worm shown in this figure has three threads, so that the losses due to friction are very small indeed.

In order to arrive at a better knowledge of the working powers of worm gear than was indicated by the usual theory, as well as to test the truth of the assertions that this form of gear was highly inefficient, Mr. Reckenzaun some years ago conducted a series of careful tests on a specially made set of worm gear. The worm was turned out of a solid cylinder of steel and highly polished. It consisted of three threads of 6in. diameter at the pitch line and 6in. pitch, gearing into a worm wheel fitted with phosphor bronze teeth of 2in. pitch. The wheel was 15¼in. in diameter at the pitch circle, and the width of each tooth was about 3½in. The velocity ratio of the gear was therefore eight. After every part had been carefully polished the gear was placed in an oil bath, and driven from an electromotor. The power supplied was measured by taking the watts supplied, and the useful power by means of Prony brakes on the spindles. The results are published in the French system of units, but the writer has reduced them to our usual system, and has also added some lines giving the total pressure and the pressure per inch width of the teeth. It will be observed that the higher efficiencies were obtained when the normal pressure between the tooth and the thread was low, *i.e.*,

Digitized by Google

when the pressure did not squeeze the oil from between their surfaces. The second test is also interesting from the fact that there is an increase of efficiency notwithstanding the increase of pressure. The reason for this is undoubtedly to be found in the increased speed of the gear, which lapped up the oil more abundantly, and carried it between the surfaces in spite of the higher pressure.

Efficiency Tests of Multiple Worm Gear.

Number of Test.	I.	II.	III.	IV.
Revolutions per min. of worm wheel	38	84	96	112
Ft. lb. supplied per min.	37,600	84,960	72,828	56,743
Ft. lb. utilised per min.	32,500	76,111	66,758	54,151
Linear velocity of wheel in ft. per min.	152	336	384	448
Thrust on tooth in lb	248	250	189	126
Thrust per inch width of tooth	71	72	54	36
Normal pressure on threads	260	263	199	132
Normal thrust per inch width of contact surface	75	76	58	38
Efficiency	84·3	89·6	91·6	95·4

From the above analysis of the series of tests it would appear that the best results are obtainable with a working resistance not exceeding 36 lbs. per inch width of tooth, and with a high peripheral velocity of the wheel. The tests make it very clear that a high efficiency is a practical possibility, and even easily attainable. A further point of interest attaches to these tests, as they show how important in engineering are the choice and careful preparation of materials. The utmost care was exercised in selecting the working materials, steel and phosphor bronze, with a light lubricating oil, being taken on account of the very low coefficient of friction which they possess. And no less care was taken to produce a reliable finish in the surfaces of the working parts; the steel worm being accurately turned out of a solid piece and finely polished, and the morticed teeth being properly trimmed and polished as well. Comparing the results which this care has produced with the experiences of engineers who have used the common cast steel or iron threads gearing into cast iron and unpolished teeth, we may consider a single example. "A very able and experienced mechanical engineer told me," writes Professor Hele Shaw, "the result of an experiment he had made with a worm and cast iron worm wheel, for transmitting power, in combination with a nut and screw, in which the efficiency of the mechanism was *only 3 per cent.*" The marked contrast speaks for itself.

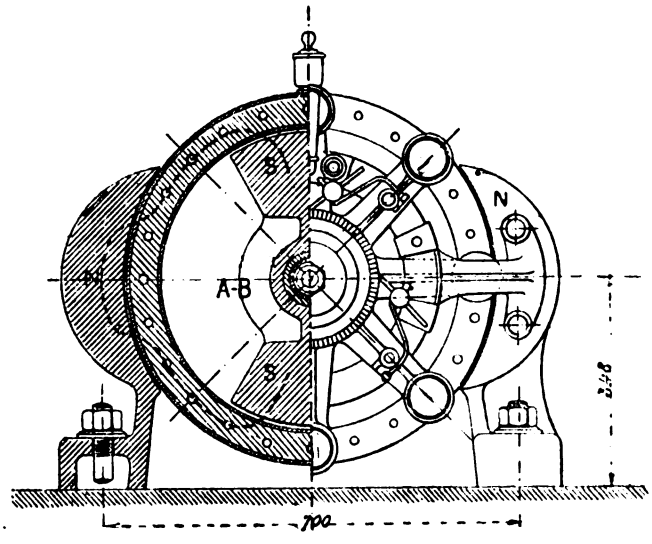
The worm gear employed by Mr. Reckenzaun on electric tramcars which he has designed differs in no important detail from the gear used in these tests, which has already been described. The running is found to be smooth and regular, the action on steep gradients certain, and the loss of power and depreciation low. Such gear will run for thousands of miles, or stand the daily wear and tear of twenty years' active work, before it is worn out. The reader is referred to a recent number of *The Electrician* (p. 63, May 20, 1892) for a very good diagram of the arrangement of worm gear on the motor trucks of the Bradford electric tramway, which will illustrate the manner in which worm gear is applied to traction work.

(To be continued.)

THE KŒCHLIN AND MARIOTTI DYNAMOS.

Dynamos having been constructed with external poles and with internal poles, the next step was evidently to bring out a machine combining both arrangements. There are several patents embodying this idea, amongst others one of Edison's, and last year the Société des Téléphones de Zürich put the Mariotti machine on the market, and the Ateliers de Constructions Mécaniques de Vevey showed the Kœchlin dynamo at an exhibition at Saint Etienne. The Esslingen Machine Works also showed a 1 H.P. motor of this type at the Frankfort Exhibition.

In the accompanying figure a Kœchlin dynamo is shown partly in section and partly in end elevation. The armature, which is of the ordinary Gramme pattern, is overhung to permit of the pole pieces embracing it externally as well as internally. The field is generated by a single coil. The machine has two pairs of poles at right angles to each other,



Kœchlin Alternate Pole Dynamo.

the N poles being outside and the S poles inside the armature, so that the lines of force are obliged to traverse the armature core. The frame is made in a single casting, extra soft steel being usually employed. The following are the data relating to the machine illustrated:—

Output at 550 revolutions (120 v × 100 a)	12,000 watts
Weight of copper on armature	18 kg.
" " " " field	72 kg.
Resistance (hot) of armature	0·86 ohms
" " " field coils	18·5 ohms
Current density in armature (3,225 per sq. inch)	5 amp. per sq. mm.
Ampere turns	8,970
Internal air-gap	10 mm.
External "	11·5 mm.
Total weight with pulley	1,100 kg.
Length of armature wire per volt	0·8 m.
Loss in watts per sq. decimetre of surface	6
Watts per kilogramme of armature wire	666
" " " total weight	11

A 6-pole 300 H.P. machine built on these lines will shortly be installed at Monthey (Valois) for transmission of power purposes.

The Mariotti machine is precisely similar to the Koechlin, with the exception of minor details.

M. A. Palaz sums up the pros and cons of this type of dynamo in *L'Electricien* somewhat as follows:—Low speed for a given voltage, and therefore peculiarly suitable for small waterfalls. Constant lead due to the extension which may in this type of dynamo be given to the pole-pieces without fear of magnetically short-circuiting the armature; good ventilation of the armature. On the other hand, the first cost of small machines of this type is excessive.

JAPANESE ELECTRICITY.

We have lately received the *Journal* of the Electrical Society, Tokyo, No. 46, Vol. IX., and the Calendar for Meiji, XXIV.—XXV., that is, for 1891-92, of the Imperial University of Japan. The latter is all in English, the former in Japanese, with the exception of a bit here and there, which is printed in English, perhaps in order that the ignorant foreigner (that is, the non-Japanese) may be properly appalled with the depth of knowledge displayed in this Tokyo electrical journal.

We reproduce (slightly reduced) the title-page as it appears in Japanese and English, and a celebrated Japanese scholar to whom we have submitted the book tells us that the title-page is

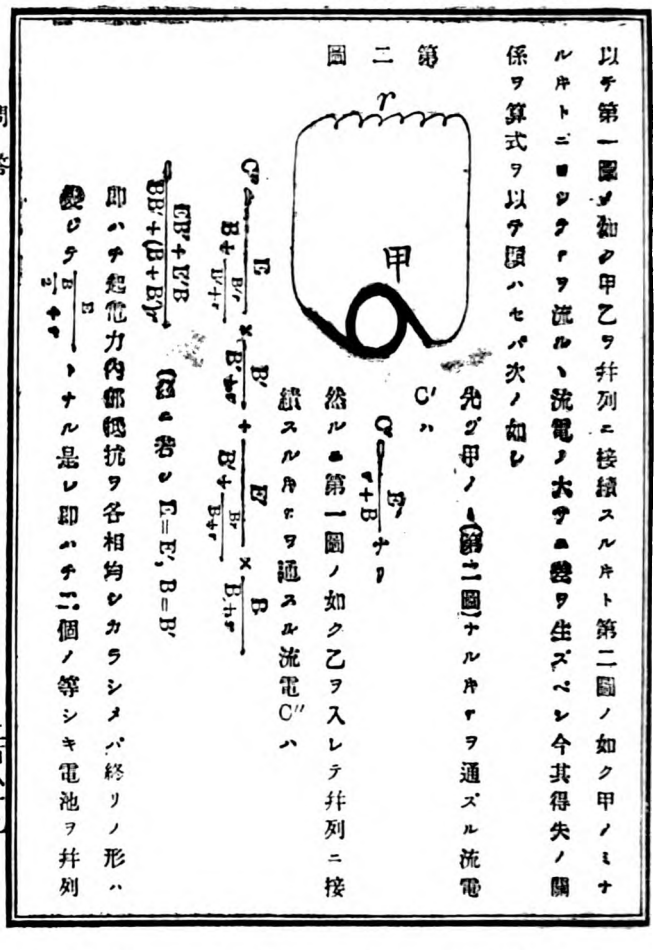
literally translated. We do not know, however, whether the first word in "Minuits of the Previous Meetings" is in the original Japanese untranslated—it is clearly not English. On the subject of the third communication, by Y. Touchiya, "Telephone Troubles, and How to Find Them," we feel that we could write volumes. We never yet met a Londoner who had experienced the slightest difficulty in finding telephone troubles, or who was seeking for help in his search. Nothing made us more touchier or more like the author of this communication, "Touchiya," than an attempt to use the telephone instrument which formerly hung up in our room in the west of London. Frequently have we unintentionally assisted in large sales of grey shirtings and pig iron between someone and someone else, who shouted so loudly, that all we could do was to assure our friend at the other end of the telephone wire—our telephone wire—that we would send a boy with a note.



To read a Japanese book you start at the right-hand top corner of what we should call the last page, then you proceed to read down each vertical column of the worm-like letters. Hence, a mathematical equation, which usually appears in English amongst these columns of Japanese characters, has to be printed standing on its end, as is seen in the sample page reproduced; and the Japanese scholar reads the equation end on without troubling to turn the page round. But this comes quite easy to a race of artists who, while they are drawing a horse, often place the picture with the animal standing on the end of its tail or on the tip of its nose. No wonder the Japanese nation is famed for its acrobatic and balancing feats.

Topsy-turvydom seems to be the characteristic of Japan. Not only do the people write and read backwards, but the carpenters saw and plane backwards; and, while in the early days of newspapers in that country manuscripts, proofs, and everything in connection with the Press could be sent post-free, to day the laws are such that the newspaper staff divides its time about equally between the editorial desk and prison. But in science and engineering the motto is forwards, not backwards; and those islands in the far East whose position,

Digitized by Google

relatively to the Pacific and Eastern Asia, is exactly similar to the position of the islands constituting Great Britain relatively to the Atlantic and Western Europe, have so closely copied our own country that not only are there several electric lighting companies in Japan, but some of them have failed to pay any dividend.

In this *Journal* of the Electrical Society of Tokyo there is a contribution in English bristling with Fourier-Bessel functions, "Note on the Vibration of Telephone Diaphragm" (observe the absence of an article before "Telephone"), by Hantarō Nagaoka, who, we find, is the Assistant Professor of Physics in the University. The result, however, arrived at towards the conclusion of the article must be pretty obvious, even to a non-mathematical telephone maker, viz., that, in order to obtain good intonation, the end of the permanent magnet should be fixed opposite the middle of the telephone diaphragm, and not to one side. This application of elaborate mathematical equations to the elucidation of self-evident facts would qualify Mr. Nagaoka to hold a chair at a British University.

A study of the Calendar of the Imperial University of Japan, which occupies some 300 pages, is more interesting, and shows the wonderful strides that country has made in the last 20 years. The University consists of six distinct colleges, respectively of Law, Medicine, Engineering, Literature, Science, Agriculture, and a University Hall; and in the Colleges of Engineering and Science alone there are no less than 31 Professors, 14 Assistant Professors, and 8 Lecturers, the chief Professor of Electrical Engineering having been a Japanese student at the City and Guilds Central Institution a year or two ago, after having previously spent over 15 years studying electrical engineering at the former Imperial College of Engineering, Tokyo, and at the Cornell and other Universities in America.

At the starting of this Imperial College of Engineering in 1873 the English professors prepared a Calendar and programme of the courses. This the authorities decided should be translated into Japanese; but the Japanese language resembles the German, in that the nouns are made up of descriptive syllables, so the translators requested to be informed of the exact meaning of such words as electric potential, magnetic flux, &c. They were assured that if they became industrious pupils they would in a few years grasp the exact meanings of such words, and then they could build up Japanese equivalents. But that would not do at all; the Government had ordered the programme to be translated, and translated at once it must be. We do not know what exact ideas the Japanese edition of the College Calendar of 1874 conveyed to the natives; but we know that the Japanese language, possessing neither the letter l nor r, but only an intermediate sound, caused one of the subjects taught, as stated in the English edition of the Calendar, to become "Natural Phirosophy," suggesting that the professor of this science was of a hotter temper than we trust the Japanese students found him to be. P. D.

ELECTRO-METALLURGY.*

BY J. WILSON SWAN.

This is not the first time a lecture has been delivered here on electro-metallurgy. I find that so long ago as January, 1841, there was a lecture on the subject by Mr. Brand. At that time electro-metallurgy was very new and very small. It consisted solely of electro-plating and electrotyping. Electro-plating had already begun to be practised as a regular industry, but it was still a question whether the new kind of plating was good, and there were not a few silversmiths who would not offer electro-plate for sale because of its supposed inferiority to plate of the old style. That question has long been definitely settled by the fact that every week more than a ton of silver is deposited in the form of electro-plate. Electrotyping in 1841 was not so far advanced—it had not then been taken hold of by the artisan and manufacturer—it was still in the hands of the amateur. While the voltaic battery was the cheapest source of electric current, electro-metallurgy was necessarily restricted to artistic metal work, or to those applications where the fine quality of the electrotype cast outweighed the consideration of its cost, or where only a thin film of metal was required for the protection of a baser metal from the action of the air. Within this limited field the electro deposition of copper, of gold, of silver, of iron, and of nickel, has been carried on commercially with very great success and advantage for almost the whole period of the existence of the art. But beyond these bounds, set by the limitation of cost, it could not pass.

Now, all this is changed—since engineer and electrician have united their efforts to push to the utmost the practical effect of Faraday's great discovery, of the principle of generating electric currents by motive power. The outcome is the modern dynamo, with its result—cheap electricity. The same cause that has led to electric lighting, and to the electric transmission of power, has also led to a very great development of electro-metallurgic industry, and not only in the old direction but in new. It is no longer a matter of depositing ounces of pounds of metal, but of tons and thousands of tons. And is no longer with metal deposition merely that electro-metallurgy now deals, but also with the extraction of metals from their ores, and the fusion and welding of metals. Electro-metallurgy has, in fact, grown so large and many-branching, that it is impossible to treat it in a complete manner in a single hour.

One of the latest developments is electric welding. This, in one of its forms, that invented by Elihu Thompson, has recently been so thoroughly explained and demonstrated by Sir Frederick Bramwell, that it is not necessary for me to do more than mention it as belonging to the subject. There is also another species of electric welding—that of Dr. Benardos—in which the electric arc is used after the manner of a blow-pipe flame, to obtain the welding of such forms and thicknesses of iron, steel, and other metals, as would be difficult or impossible to weld in any other way; and not only is the electric blow-pipe used for welding, but also for the repair of defects in steel and iron castings, by the fusion of pieces of metal, of the same kind as the casting, into the faulty place, so as to make it completely sound. This new kind of electric welding, as improved by Mr. Howard, is now of sufficient importance to entitle it to the full occupation of an evening. I therefore propose to leave it for detailed description to some other lecturer, and content myself with calling your attention to the interesting collection of specimens on the table, and in the library (lent by Messrs. Lloyd and Lloyd), showing the results of this process.

Even with this curtailment, the extent of the field is still too great, and I must reduce it further by omitting a considerable section of that portion which relates to the extraction of metals from their ores, and, in this connection, only speak of the extraction of aluminium. But, in the first place, I am going to speak of the deposition of copper. One of the wonderful things about the electro-deposition of copper, and, in fact, any other metal deposited from a solution of its salt in water, is, that bright, hard, solid metal, such as we are accustomed to see produced by means of fusion, can, by the action of the electric current, be made to separate from a liquid which has no appearance of metal about it.

For the reproduction of fine works of art in metal, electrotype is unapproachable. The extreme minuteness with which every touch of graver or modelling-tool is copied by the deposited metal film, separates electrotype by a wide space from all other modes of casting. Even the Daguerreotype image is not too exquisitely fine for electrotype to copy it so perfectly that the picture is almost as vivid in the cast as in the original. It is this quality that has given to electrotype a *rôle* which no other process can fill, and, so far, its practical utility is not greatly dependent on the cost of the current. This applies to all those most beautiful things here and in the Library, lent by Messrs. Elkington. These could all have been produced commercially, even if there had been nothing better for the generation of the current than Smee's battery—a very good battery, by the way, for small operations in copper deposition. It gives a very low electromotive force, and that is a defect; but in copper deposition, the half-volt or so is generally sufficient to produce, automatically, the required current destiny. One of the uses of electrotype, not greatly affected by the cost of deposition, is that of the multiplication of printing surfaces. In these days of illustrated periodicals, electrotype has come more and more into use for making duplicate blocks from wood engravings, which would soon be worn out and useless if printed from direct. It is also employed to make casts from set-up type, to be used instead of ordinary stereotype casts, when long numbers of a book have to be printed; also as a means of copying engraved copper-plates. Here are examples of all these uses of the electrotype process. The electro-blocks are lent by Messrs. Richardson and Co., and the copper-plates by the Director-General of the Ordnance Survey Office, Southampton. The plates illustrate the method employed at Southampton in the map-printing department. The original plates are not printed from except to take proofs. The published maps are all printed from electrotypes. Here is an original plate—here the matrix or first electro, with, of course, all the lines raised which are sunk in the original. The second electro is, like the original, an intaglio. Here is a print from it, and here one from the original plate.

* Friday evening discourse delivered at the Royal Institution.

Practically they are indistinguisable from each other, and bear eloquent testimony to the wonderful power of electrotype to transmit an exceedingly faithful copy of such a surface.

Nickel has, of late years, come into extensive use for what is termed nickel-plating, as applied to coating polished steel and brass with nickel. Nickel not only has the advantage over silver of cheapness, but also, in some circumstance, of greater resistance to the action of the air.

Another metal, usually deposited in the form of a coating, is iron. The electrolytic deposit of iron is peculiarly hard—so much so, that it is commonly but erroneously spoken of as *steel*-facing. The deposition of a film of iron upon engraved copper plates, as a means of preventing the wear incidental to their use in being printed from, has become almost universal. Valuable etchings, mezzotints, and photogravure plates are thus made to bear a thousand or more impressions without injury. By dissolving off the iron veil with weak acid, when the first signs of wear appear on the surface of the plate, and re-coating it with iron, an engraved copper plate is, for all practical purposes, everlasting. In this case, of course, the film of iron is extremely thin—one or two hundred-thousandths of an inch. But it is possible to produce most of the metals commonly used as coatings in a more massive form. Here, for example, is an iron rod half an inch in diameter, entirely formed by electrolytic deposition. I am indebted to Mr. Roberts-Austen for being able to show this.

These are all departments of electro-metallurgy which would have maintained a perfectly healthy industrial existence and growth without the dynamo; but now I come to speak of a branch of the subject—electrolytic copper refining—which, without that source of cheap electricity, could not have existed. This is the most extensive of all the applications of electro-chemistry, and is rendering valuable assistance to electrical engineering by the improvement it has led to in the conductivity of copper wire. One of the results of this is seen in the raising of the commercial standard of electrical conductivity Ten years ago contracts for copper wire for telegraphy stipulated for a minimum conductivity of 95 per cent. of Matthiessen's standard of pure copper. Now, chiefly owing to electrolytic refining, a conductivity of 100 per cent. is demanded by the buyer and conceded by the manufacturer.

To show the difference between the past and present state of things in relation to the commercial conductivity of copper, I am going to exhibit on the screen measurements of the resistance of six pieces of wire of equal length and equal cross section—they have been drawn through the same drawplate. Three of the pieces are new and three are old. The three new pieces are made from electrolytic copper, and are representative of the present state of things. The three old pieces are taken from three well-known old submarine telegraph cables, and they show how very bad the copper was when it was first employed for telegraphic purposes, and how great has been the improvement. I will take No. 1 wire as the standard of comparison. It is a piece of the wire about to be supplied to the Post Office Telegraph Department for trunk telephone lines. It will show the very high standard of conductivity that has been reached in the copper of commerce. I am indebted for it, and for two out of three of the old cable wires, to Mr. Preece. No. 2 wire is made from electrolytic copper, deposited in my own laboratory. No. 3 is also electrolytic copper, but such as is commercially produced in electrolytic copper refining; it has been supplied to me by Mr. Bolton, to whom I am also indebted for wire No. 6—a particularly interesting specimen; it is from the first Trans-Atlantic cable—the cable of 1858. No. 4 wire is from the Ostend cable of 1860, and No. 5 wire is from the old Duth cable. These wires are so arranged that I can send a small and constant current partly through any one of them and partly through a galvanometer. When this is done the result will be a deflection of the spot of light on the scale from the zero point to an extent corresponding to the resistance of the particular wire in the circuit. The worse the wire is, the greater will be the deflection. We will begin with the Post Office sample first. I connect the galvanometer terminals to wire No. 1; you see there is a deflection of ten degrees. I will now shift the contacts to wire No. 2—exactly the same length of wire is included—but now you see there is a deflection of slightly less than ten degrees, showing that this wire has a little lower resistance than No. 1. The difference is very small—it may be 2 per cent.—and 2 per cent. less if it would be required to conduct as well as the No. 1 wire. The next is No. 3. This is Mr. Bolton's wire, and shows a resistance almost equal to the last. Nos. 1, 2, and 3 are, therefore, nearly alike, and have a degree of conductivity almost as high as it can possibly be. Now we come to the three old wires. We will take No. 4 (the Ostend cable). There, you see, is a great difference. Instead of the spot of light being on the tenth degree, it was upon the eleventh. We will now try No. 5 (the Dutch cable). That drives the index to 17. Now I change to No. 6 (the old Atlantic cable), and we have a deflection of no less than 25deg. I suppose we may assume that this wire fairly represents the commercial conductivity of copper in 1858, for it is highly probable that for a work so important as the first Atlantic cable every care would be taken in the selection of the copper. The result of this experiment shows that the copper of that cable was extremely bad as a conductor—that, in fact, it is 150 per cent. worse than the best commercial copper of to-day. In other words, it shows that, in point of electrical conductivity, one ton of the copper of to-day will go as far as two and a-half tons of such copper as was used for the cable of '58. This change is largely due to electrolytic copper refining. To prepare the crude copper for the refining process it is cast into slabs. The cathodes are formed of thin plates of pure copper. Here are plates such as are used in electrolytic copper refining works. They are portions of actual cathodes and anodes, and represent the state of things at the commencement, and at the end, of the depositing operation—an operation that takes several weeks to complete, and effect the great change these plates show. In copper refining works an immense number of these plates, each having 6 to 10 square feet of superficial area, are operated upon together in a great number of large wooden vats containing sulphate of copper solution and a small proportion of sulphuric acid. Electric current from a dynamo, driven by a steam-engine or water-power, is conveyed by massive copper conductors to the vats, arranged in long lines of 50 or 100 or more in series. Thick copper bars connect adjoining vats, and provide a positive and negative support for the plates, which hang in the solution opposite each other, two or three inches apart. During the process the impure slabs dissolve, and at the same time pure copper is deposited from the solution upon the thin plates. The deposition and dissolving go on slowly, in some cases very slowly, for a slow action takes less power, and gives purer copper than a more rapid one. The usual rate is one to ten amperes per square foot of cathode surface. You will better realise what these rates of deposit mean, when I say that one ampere per square foot rate of deposition gives for each foot of cathode surface, nearly one ounce of copper in 24 hours, and a thickness of one-eight hundredth of an inch; and therefore the production of one ton of copper at that rate in 24 hours would require a cathode surface in the vats, in round numbers, of 36,000 square feet. At the higher rate of 10 amperes per square foot, which is used where coal is cheap, one-tenth of this area would be required.

The importance of the electrolytic copper refining industry, and the extent of the plant connected with it, may be inferred from the fact that, reckoning the united production of all the electrolytic copper works in the world, nearly one ton of copper is deposited every quarter of an hour. Very little power is required for copper deposition if the extent of the dissolving and depositing surfaces is large, relatively to the quantity of copper deposited in a given time. Some of the impurities ordinarily found in crude copper are valuable. Silver and gold are common impurities, and these and some other impurities do not enter into solution, but fall down as black mud, are recovered, and go to diminish the cost of the process or increase the profit; and even those impurities which enter into solution are, under ordinary condition, almost completely separated.

Electrolytic copper refining is both an economical and an effective process. The deposited copper is exceptionally pure. At one time it was supposed that it must necessarily be quite pure, but this is not the case; other metals can be deposited with the copper, but it is not difficult to realise in practice a close approximation to absolute purity in the deposited copper. Here is an example of the deposition of a mixed metal—brass, that is, copper and zinc deposited together, and there are in the Library a number of interesting specimens of mixed metal deposition. These deposits of brass and other alloys show that more than one metal can be deposited at the same time. The great enemy to conductivity in copper is arsenic, and the deposition of arsenic as well as copper is one of the things to be guarded against in electrolytic copper refining. Not only are the chemical characteristics of electrolytically refined copper generally good, but its mechanical properties are largely controllable. Usually electrolytic copper is melted down and cast into billets of the form required for rolling and wire-drawing. This treatment not only involves cost, but the copper is apt to imbibe impurity during fusion; though, if the process is carefully conducted, the deterioration is slight.

But it is evident that the re-melting of the deposited copper is a thing to be avoided if possible, and the question naturally arises, why, now that deposition costs so little, may not the beautiful principle which comes into play in electrotope, and which enables the most complicated forms to be faithfully copied be taken advantage of to give to plainer and heavier objects their ultimate form?

There are several reasons why this idea is not more frequently acted upon. One is that the process of electrolytic deposition is slow; another, that knowledge of the conditions necessary for obtaing a deposit having the required strength and other qualities is not very widespread. Moreover, in the electrolytic deposition of copper, and, indeed, of all metals, there is a strong tendency to

Digitized by Google

roughness on the outside of the deposit, and to excrescent growths, the removal of which involve waste of labour and material. These tendencies can, to a very great extent, be counteracted by careful manipulation and the use of suitable solutions, and they can also be counteracted by mechanical means. This has been done by Mr. Elmore. He remedies the faults I have mentioned by causing a burnisher of agate (arranged after the manner of a tool in a screw-cutting lathe) to press upon and traverse a revolving cylindrical surface on which the deposit is taking place, and while it is immersed in the copper solution. The result is that it is kept smooth and bright to the end of the process. But the use of a burnisher is not the only means available for the production of a smooth deposit. It was observed in the early days of electro-plating how great a change was effected in the character of the metal deposited by the presence of a very small quantity of certain impurities. It was found, for example, that an exceedingly minute dose of bisulphide of carbon, if put into a bath from which the silver was being deposited, caused the deposit to change from dull to bright.

I have lately had experience of a similar kind with nickel and with copper. I was working with a hot solution of nickel, and up to a certain point the deposit had the usual dead-grey appearance. Suddenly, and without doing anything more than putting in a new cathode, I found the character of the deposit completely changed. Instead of the grey, tough, adherent deposit, there was produced a brittle, specular deposit, which scaled off in brilliantly shining flakes of metal. I sought for the cause of this extraordinary change, and traced it to the accidental introduction into the solution of a minute quantity of glue. By adding gelatine to a fresh nickel solution I obtained the same peculiar bright and brittle deposit that had resulted from the accident. I then made a similar addition to a solution of copper, and when I hit the right quantity—an exceedingly minute one—bright copper, instead of dull or crystalline, was deposited. Here are some specimens. These were deposited on a bright surface, and they are bright on both sides.

Not only is the copper made bright, under the conditions I have described, but, if the proportion of the gelatine be carried to the utmost that is consistent with the production of a bright deposit, it becomes exceedingly hard and brittle. Beyond this point the deposit is partly bright and partly dead, the arrangement of the patches of dead and bright being in some cases very peculiar, and suggestive of a strong conflict of opposing forces.

Before I leave the subject of copper deposition, I may mention that I have found the range of current density within which it is possible to obtain a deposit of reguline metal, far wider than is commonly supposed. The rate of deposition in copper-refining is usually very slow, and it is one of the drawbacks of the process, since slow deposition necessitates large plant. But rapid deposition necessitates a larger consumption of power, and larger cost on that account, and, therefore, there is a point beyond which it is not good economy to go, in the direction of more rapid deposition. Still there are cases where, if we had the power to deposit more rapidly, it might be found useful to exercise it. The subject of more rapid deposition is also interesting from a scientific point of view, I therefore mention an unusual result I have arrived at in this direction.

Taking as one extreme, the slow rate of deposit, of one ampere per square foot of cathode—a rate not infrequent in copper-refining, I have found that the limit in the other direction is not reached by a rate of deposit 1,000 times faster. I have produced, and I hope to be able to produce before you, a perfectly good deposit of copper, with a current density of 1,000 amperes per square foot of cathode.

This cell contains a solution of copper nitrate, with a small proportion of ammonium chloride. The plate on which I am going to produce a deposit of copper has an exposed surface of 21 square inches. Opposite, at a distance of one inch, is a plate of copper. When I close the circuit, a current of 140 amperes is passing through the solution. I continue this for just one minute. Now I wash it and remove the outer edge so as to detach the deposit, and as you see, I have a sheet of good copper—an electrotype. To have prodced a deposit of this thickness at the ordinary rate used in electrotyping operations would have occupied more than an hour.

In this experiment an extreme degree of rapidity of deposition has been shown. I do not intend to suggest that a rate of practical value. But it is at least interesting, as showing that the characteristic properties of copper are not less perfectly developed when the atoms of metal have been piled up one on the other at this extremely rapid rate than when there is slower aggregation. I think it probable that the rate of deposit intermediate between this rate and the usual one of about ten amperes per square foot may frequently be useful, for no doubt the slowness of the rate of deposit has often prevented electrotype from being made use of where, if the rate could have been increased ten times, it might have been used with advantage. Here are some thick plates, deposited at the rate of 100 amperes per square foot. They are as solid and as free from flaw as plates deposited ten time more slowly.

I said that electrolytic copper refining owed its existence to the discovery and improvement of the dynamo, and that other electro-metallurgic industries had originated from the same cause. One of these industries is the electrolytic production of aluminium. When Deville produced aluminium by the action of sodium on aluminium chloride, exaggerated expectations were entertained of the great part it was about to play in metallurgy. It was very soon found that aluminium had not all the virtues that its too sanguine frfends had claimed for it, but that it had a great many most valuable properties, and, given a certain degree of cheapness, a number of useful applications could be found for it. Some of these are suggested and shown by the various articles made of aluminium, kindly lent by the Metal Reduction Syndicate, and metallurgical research is rapidly extending our knowledge of its importance in connection with the improvement of steel castings, and the production of bronzes and other alloys of extraordinary strength. The cost of aluminium produced by Deville's process was too great to permit of its use on any large scale for these purpurposes. After Davy demonstrated, by the electrolytic extraction of potassium and sodium, the power of the electric current to break down the strong combination existing between the alkaline metals and oxygen, it seemed natural to expect that aluminium would also be reduced by the same means. But Davy did not succeed in producing any appreciable quantity of aluminium by the electrolytic method. Deville and Bunsen were more successful, but they did not possess the modern dynamo; that has made all the difference between the small experimental results they achieved and the industrial production of to-day, a production now so large that I suppose every day it amounts to at least one ton, and has resulted in a very great reduction of the price of the metal.

There are two electrolytic processes at work. One is the Hall process—employed at Pittsburg, and at Patricroft, Manchester—and now in experimental operation here. The other, the Herault process, worked at Neuhausen, is not greatly different from the Hall process—the shape of the furnace or crucible is different, and the composition of the bath yielding the aluminium may be different, but in all essentials these two processes are one and the same. They depend on the electrolysis of a fused bath, composed of cryolite, aluminium fluoride, fluorspar, and alumina. In the Hall process this mixture is contained in a carbon-lined iron crucible—the cathode in an electric circuit; and between which and the anode—a stick of carbon immersed in the fused bath—a difference of potential of 10 volts is maintained. In carrying out the process on a manufacturing scale, there are many of these sticks of carbon to each bath. Here, in our experimental furnace, there is only one.

The heat developed by the passing of so large a current as we are using (180 amperes) through an electrolyte of but a few inches area in cross section, is sufficient to melt and keep red hot the fluorides in which the alumina is dissolved. The electrolytic action results in the separation of aluminium from oxygen. The metal settles to the bottom of the pot, and is tapped or ladled out from time to time as it accumulates. The oxygen goes to the carbon cylinder, and burns it away at about the same rate as that at which aluminium is produced. It is only necessary to keep up the supply of alumina to enable the operation to be continued for a long time. I mean, of course, in addition to the keeping up of the current and the supply of carbon at the anode.

By far the greater part of the cost of aluminium obtained by electrolysis is the cost of motive power; 20 horse-power hours are expended to produce one pound of aluminium. Therefore it is essential for the cheap production of aluminium to have cheap motive power. There is one feature about the Neuhausen production of aluminium which is very striking, and that is the generation of the electric current by means of water power derived from a portion of the falls of the Rhine at Schaffhausen. The motive for making use of water power is economy. But, apart from that, it is interesting to see water replacing coal, not only in the production of power, but also in the production of the heat required in a smelting furnace.

Here is the Hall apparatus on a small scale. It is simply a carbon-lined iron crucible, and a thick stick of carbon. As already mentioned, the crucible is the cathode, the stick of carbon the anode. As the process takes time to get into full operation, it was commenced some hours ago, and at the rate at which it has been working we should by now have produced several ounces of aluminium. In beginning the process the charge has first to be melted. This is done by bringing the carbon stick into contact with the bottom of the crucible, so as to allow the current to pass from carbon to carbon to develop heat between the electrodes. The alumina compound, which, when melted, forms the bath, is added, in powder, little by little, and, when sufficient is melted, the carbon stick is raised out of contact with the bottom, and the electrolytic action then commences.

Here is the result of our experiment. It is not very large certainly, but it is quite enough for our purpose, which is to illustrate the principle of a newly-developed electro-metallurgical industry directly derived from discoveries made at the Royal Institution.

GREENWOOD AND BATLEY'S ARC-LIGHT DYNAMO.

The Hochhausen dynamo appears at first sight to have been modified by Messrs. Greenwood and Batley, of Leeds, until it is hardly recognisable; but closer inspection of the illustration of this firm's new arc light machine shows that the rejection of the fantastic field magnets is the most noticeable feature, several of the original details, such as the air-insulated commutator, brush-holders, and main switch being retained. The mounting of the brushes on a large ring running on sheaves is still found on this machine, for it is part of the regulating system which is characteristic of the dynamo. The curious magnet yokes having been abandoned for a sensible arrangement, it has become necessary to modify the motor which is now placed in a subsidiary or shunted magnetic field between two projections from the pole pieces.

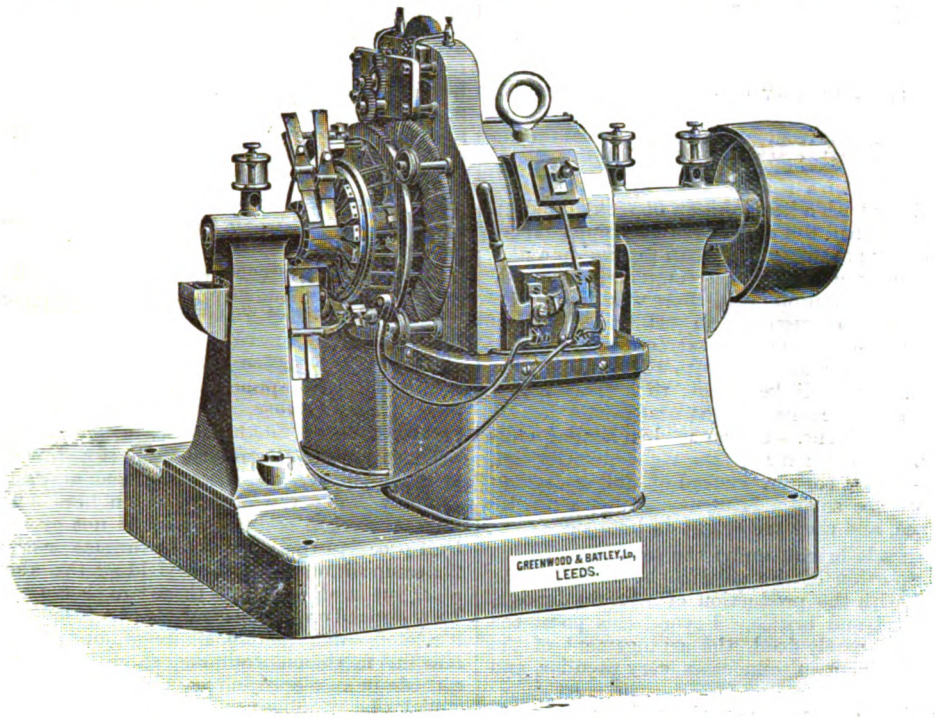

FIG. 1.—Greenwood and Batley's Arc Light Dynamo. General View.

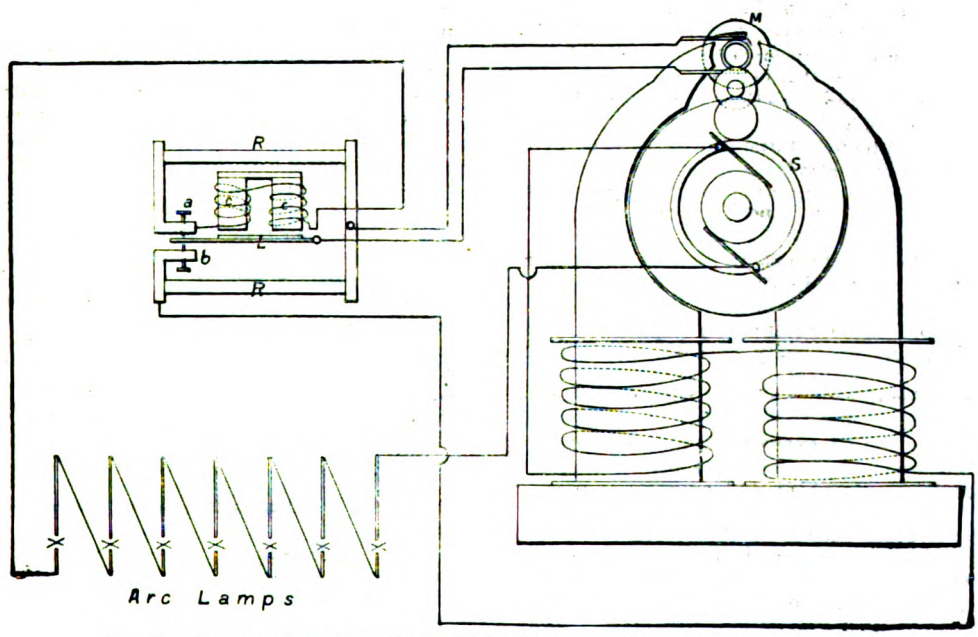

FIG. 2.—Greenwood and Batley's Arc Light Dynamo. Diagram of Regulating Gear

Fig. 1 shows the general arrangement of a 20-light dynamo with the regulating gear attached. In Fig. 2 the circuit is represented in diagrammatic form. A little flat ring armature M is provided with an ordinary commutator and a pair of brushes receiving a weak current through an automatic reversing switch. This switch consists of an electro-magnet energised by the main current, an armature L, which can make contact with either of the terminals *a* and *b*, and two resistances R, consisting of carbon rods about ½in. in diameter and some 6in. long. A small variation of the electromotive force in the main circuit will cause the armature L to make contact through *a* or *b*, as the case may be, and send a current through the armature M, in one direction or the other, and thus cause the latter to revolve forwards or backwards. By virtue of this rotation of M the circular rack S, supporting the brush-holders of the dynamo, will move slowly (it being driven through a small train of wheels geared to the spindle of M), and thus adjust the position of the dynamo brushes to suit the electromotive force demanded by any number of arc lamps arranged in series. The following tests have been made on a 20-light machine:—The machine was driven by an electric motor, the brake horse-power of which was easily ascertained, running at a constant speed of 750 revolutions per minute. The current was constantly at 10 amperes, and the average voltage measured 47 volts per lamp.

The regulator absorbs only 21 watts or about ¼ per cent. of the maximum load—quite a negligeable quantity. There is no sparking at the contact maker, and, when once adjusted, the

Digitized by Google

automatic regulator will act promptly and without any further attention except an occasional dusting.

Tests of the "Leeds" Arc Dynamos.

COAST COMMUNICATION.

As was announced at the end of the last Parliamentary session, the Post Office, pending the publication of the Report of the Royal Commission on the telegraphic connection of lighthouses and lightships with the shore, had been directed to proceed with the carrying out of a scheme of telephonic communication between the chief coastguard stations and the nearest lifeboat stations. A sum of £20,000 was voted by Parliament for the work in the current financial year, and the following lines have, according to the *Post Office Magazine*, either already been or shortly will be run. All are telephonic circuits except where otherwise stated.

Coastguard Stations at Dungeness, Grand Redoubt, Station No. 1, Station No. 2, and New Romney.

Coastguard Stations at Ramsgate, Broadstairs, North Foreland, Kingsgate, Newgate, and Margate.

Coastguard Stations at Deal, Station No. 2, Sandwich, and Ramsgate.

Oxwich to Port Eynon Post Office and Rhossili.

Pembroke Dock Post Office to Angle Post Office and Coastguard Station.

An A B C line from Llantwit to Porthcawl and Swansea.

From Morthoe to Ilfracombe on the one side, and to Croyde on the other.

From Hartland Quay to Clovelly on the one side, and Bude on the other.

From the Lizard to Cadgwith on the one side, and to Mullion and Porthleven on the other.

From Swanage to Studland Bay on the one side, and to St. Alban's Head, Bottom, and Kimmeridge on the other, combined with an extension of an existing wire between St. Alban's Head and Corfe Castle to Poole, in order that the lifeboat there may be brought within call of the Coastguard Stations, as well as the lifeboats at Swanage and Kimmeridge.

From Beachy Head to Eastbourne on the one side, and to Newhaven and five intermediate Coastguard Stations on the other.

Extension of an existing A B C circuit between Kingsbridge and Prawle, to Salcombe on the one side, and to Rickham and Hall Sands on the other.

Telegraphic communication to Pennan, a village on an exposed part of the Scotch Coast, midway between the Lifeboat Stations at Fraserburgh and Banff.

A telegraph circuit from Hunstanton to Skegness.

Happisburgh to Palling, Thwart Lights, and Winterton.

Winterton to Caistor, Yarmouth, and Gorleston.

A telegraphic extension from Whiting Bay Post Office to Kilmorie Post Office.

Timoleague Post Office to Courtmacsherry Post Office and Coastguard Station.

The Coastguard Stations at Hunstanton, Thornham, and Brancaster Staith.

Croyde Coastguard Station to Appledore Post Office.

Appledore Post Office to the Coastguard Stations at Westward Ho! Peppercombe, and Clovelly.

The Coastguard Stations at New Clee, Cleethorpes, Tetney Lock, North Coates, and Donnanook.

Beal Post Office to Holy Island Coastguard Station and Post Office.

Beal Post Office to Goswick Coastguard Station.

Bamborough Post Office to Budle Coastguard Station.

Beadnell Coastguard Station to Seahouses Coastguard Station and Post Office.

Call bells in the Post Offices at Beal, Seahouses, Bamborough, Spittal, and Berwick.

Coastguard Stations at Winchelsea, Rye Harbour, Camber, Jury Gap, Galloways, and Dungeness.

Coastguard Stations at Dartmouth, Tor Cross, and Hall Sands.

Coastguard Stations at Salcombe, Sharp Tor, Bolt Head, Steeple Cove, Hope Cove, Bantham, and Challabrough.

Yealm Coastguard Station to Plymouth Post Office.

Coastguard Stations at Challabrough, Kingston, Mothecombe, Gunrow Head, and Yealm, and also the Chief Coastguard Officer's House at Yealm.

Coastguard Stations at Mevagissey, Gorran Haven, Dodman, Greeb, and Caerhays.

Coastguard Stations at Portscatho, Carne, Porthloe, and Caerhays.

Coastguard Stations at Cadgwith, Coverack, Porthoustock, Porthallow, and Gillan Creek.

Burry Port Coastguard Station, Burry Port Look-out, and Ferryside Post Office.

An arrangement for giving direct communication between Ferryside and Tenby Post Offices after official hours.

Post Office to Coastguard Station at Tenby.

Post Offices at Tenby, Saundersfoot, Amroth, Pendine, and Laugharne.

Coastguard Stations at Portscatho and Falmouth.

Telephone lines and submarine cables connecting the various Coastguard Stations in the Scilly Islands.

A telegraph extension to Fair Isle, Shetland.

THE INFLUENCE OF THE ELECTRIC LIGHT ON THE STRUCTURE OF HERBACEOUS PLANTS.*

BY GASTON BONNIER.

In a previous communication† the author showed that the structure of the leaves and young shoots of trees exposed continuously for a lengthy period to a globe-covered arc lamp, giving a constant light, underwent certain modifications. In the present communication the author describes some results relating to herbaceous plants cultivated under similar conditions and exposed also to the naked arc. Plants from which it was desired to cut off the rays were placed under a blackened screen. The plants were placed from 1·5 metre to 4 metres from the arc.

The author shows that powerful assimilation goes on in plants exposed to the electric light. The rate of assimilation is double that which obtains when plants are exposed to diffused sunlight, and is more than one quarter of that which obtains when plants are directly exposed to the strongest rays of the sun.

Like previous investigators, the author finds that some plants perish even when intermittently exposed to the electric light, especially if the arc is naked. A certain number of plants exposed continuously to the light of a globe-covered lamp, on the other hand, exhibited an exuberant development, the leaves being an intense green and the flowers deeply coloured. The greater number of such plants, however, appeared to suffer from this rapid development.

No notable anatomic modification was observed in the case of submerged aquatic plants, although their buds were greener when exposed to continuous light. Plants exposed direct to the naked arc light frequently had their tissues hypertrophied, or exhibited abnormal formations.

The author's conclusions are as follows:—(1) When the continuous glass-covered electric light causes considerable development in a herbaceous plant with an intense green colouration, the structure of the parts is at first very much differentiated; but if the electric light is powerful, and its application is prolonged for months without cessation or diminution, the newly-formed parts of such plants as are able to adapt themselves to this illumination exhibit remarkable structural modifications of the tissues, these being less differentiated although always rich in chlorophyll. (2) The naked electric light is detrimental by reason of its ultra-violet rays to the development of the tissues, even when the plants are more than 3 metres distant from the lamp.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 23, 1892.

Meeting of the Street Railway Association of New York.—The annual meeting of the Street Railway Association of the State of New York was held on Tuesday last at Saratoga, N.Y. This association is composed of the representatives of the leading street railways in the State, and although every effort has been made a number of times to secure something like a complete representation, the fact remains that only the larger companies are members of the association. At the meeting this week a smaller number than usual was represented, and, although five companies have joined the association during the year, the secretary called attention to the fact that the tendency of the times to consolidation had reduced the membership of the association to about two-thirds of what it formerly was. The two important features of the convention were the reading and discussion of Mr. McIntire's report on recent improvements in electric railways, and the organisation of what is to be called the Association of Dealers in Street Railway Supplies. Mr. McIntire's Paper dealt with the different features of the operation and construction of electric railways, and the discussion that followed it was chiefly taken up with the subject of track. The general opinion seemed to be that the faulty track construction, so often met with in street railways now in operation, was due to the fact that the companies had disregarded the experience gained by steam railroad engineers, and were not giving enough attention to the making of a solid joint between two consecutive rails. The organisation of an auxiliary branch of the association made up of the supply men, who, by the way, were more numerous at this convention than the members, is a new departure. This new association intends to assist the members of the parent association in attaining the objects for which the latter was organised, and to promote in every way possible the interests of street railway men throughout the State.

A Large Alternator.—The General Electric Company has taken in hand in a vigorous way the construction of large alternators for central station use. A plant is now in process of construction at the station of the Narragansett Electric Lighting Company, of Providence, R.I., in which the unit is a 375-kilowatt alternator, coupled direct to an Allis-Corliss compound engine, running at 90 revolutions per minute. The armature of the alternator replaces the flywheel of the engine, the field coils being carried upon a frame which rests upon the same base as the engine. The number of poles is in the neighbourhood of 80. It is expected that the machine will be ready for operation in three or four weeks, and will mark a distinct advance in the construction of electric lighting apparatus in this country. There is no mistaking the decided tendency towards larger units in stations where it is possible to make use of them. The General Electric Company is also building units for railway use which run as high as 500 or 600 kilowatts capacity.

The Niagara Falls Scheme.—The Cataract Construction Company, which up to this time has depended very largely upon foreign sources for advice in regard to electrical matters, has, it is understood, engaged the services of Prof. Henry A. Rowland, of Johns Hopkins University, as consulting electrical engineer. Prof. Rowland is now in New York City giving attention to some of the details of the work, and has been in consultation with some of the officials and engineers of the Company.

NEW YORK, *October* 1, 1892.

The Overhead Trolley System in New York.—The introduction of the trolley system into the upper section of New York, commonly known as the annexed district, was but the entering wedge. At a special session of the Board of Aldermen, held on Thursday, a franchise for the construction of trolley roads through the down town districts of New York were granted with such liberality that even the advocates of the trolley system have no reason to complain. About a month ago the large New York dailies took up the question of the dangers of the trolley system and treated the public for several weeks to column after column of reports of alleged accidents in different cities where the trolley had been introduced. Finally, however, their stock of information became exhausted, and for the last two or three weeks very little opposition has been evinced by the daily press. A number of papers have, indeed, printed articles more temperate in tone, and some even advocated the introduction of the trolley. Some of these articles evidently emanated from electric railway companies who were agitating to secure franchises in the down town sections of the city. Whatever their origin, they were soon followed by the action of the Aldermen on the applications made a short time ago, which had temporarily been referred to the Street Railway Committee. At the meeting on Thursday no less than nine franchises were granted, covering, perhaps, 12 to 15 miles of line in all, and permission was given in most cases to use the trolley system if desired. About 12 miles of the line is a surface road running directly under the structure of the elevated railway. This is, of course, one of the very best localities in the city for the use of the trolley, as overhead wires can here be attached directly to the high beams of the elevated railway. The vote with which these franchises were passed through the Board of Aldermen was 15 to 5, and, of course, the usual allegations of improper influence are rampant. The prime mover in the scheme is Mr. John D. Crimmins, well known as a big municipal contractor.

Test of a Stanley Transformer.—A recent test of a Stanley 17,500-watt transformer, made by Prof. Ryan, of Cornell University, shows excellent results. The method used by Prof. Ryan was similar to that described in his Paper on transformers before the American Institute of Electrical Engineers about two years ago, power dissipated through hysteresis, eddy currents, &c., being determined by the use of a contact maker, condenser and electrometer. The frequency was 132 ∽. The primary voltage being 1,000 and the secondary 50 volts, the drop in pressure from no load to full load was 2·3 per cent. The final results as to efficiency showed that the efficiency was 96·9 per cent.; at half load 97·1; at quarter load 96, and at one-eighth load 93; for one 16 c.p. lamp the efficiency as measured was about 24 per cent., the all-day efficiency was about 93·8 per cent., assuming that the transformer had a working output equivalent to 17,500 watts for five hours out of every 24.

The Siemens and Halske Electric Company of America.—The Siemens and Halske Electric Company of America are getting ready for business. A number of different types of machines will soon be placed upon the market. The Company will make a speciality, as was announced some time ago, of very large machines, the intention being to place generators and engines as high as 1,000 H.P. each upon the market immediately, or as soon as they can be constructed; at any rate, they will offer these for sale to whoever cares to purchase them. It was supposed by some that the Company would build machines of American design, but the latest information shows that the plans and designs for all their apparatus will be drawn direct from the large establishment in Germany, and the machinery constructed will conform to the designs that have already been tested in German establishments.

CORRESPONDENCE.

NAVAL SIGNALLING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Lieutenant Bacon, R.N., of H.M. torpedo ship "Vernon," Portsmouth, has thought fit to call in question, in your issue of the 30th ult., the value of my A B C system of electric signalling shortly referred to in your article of September 16th and in my letter of the 21st.

If I rightly understand it, the Baconian theory is (1) that I have "totally mistaken the signalling requirements of the Navy"; (2) it is very little importance to the Navy that signals may be read easily; (3) it is impossible to shortly state what the Navy *does* want in the way of signalling, since long and

Digitized by Google

short messages have to be sent; (4) the Navy tries to get the best to suit the requirements which Lieut. Bacon finds it so difficult to define; (5) there are great disadvantages in the "flashing" and other systems in use; (6) that if presented to the Admiralty, and it passes the "first line of defence" (the Permanent Official), my invention will have a fair trial; (7) that, generally speaking, it is the exception for "shoregoing" people, or other than naval officers, to have any knowledge of life, or opportunities of noting "the conditions that surround life at sea"; (8) that because improved signalling is demanded by every craft great deliberation is necessary.

Lest it may appear to your readers that the writer is a "fearful example" of the "shoregoing" type, it may, perhaps, not be improper if I state that, as a native of a seaport town and the son of a naval man, my early associations were nautical. Entering the Greenwich Hospital School in 1858 (when Lieut. Bacon was a *quantité négligeable*), in the same year I made my first ocean passage and since then many others, which, in point of numbers and variety, will, I venture to think, compare favourably with the experiences of Lieut. Bacon during the 15 years he has been in the service, observing that, as the guest of naval captains and otherwise, I have witnessed nearly every operation, short of actual war, performed on board ships.

But the material point is that I claim to have invented a simple and ready system of signalling. Mr. Bacon says I have not. Again, is that system likely to meet with an immediate and fair trial in the Navy? To this question I must reply in the negative. Speaking with a painful experience of 16 years of Admiralty treatment in connection with my first invention, known as Kelway's Electric Log, I must conscientiously say that the official action has been scandalous. Similarly with other inventions I have since submitted.

The whole system of Governmental dealing with inventions is as unsatisfactory and unfair now as it was in 1872, when a British Association Committee reported at the Brighton meeting as follows:—

The Committee considered it fully established that the present methodical mode of dealing with inventions submitted to the different departments of Government was uncertain and unsatisfactory in itself, frequently unjust to inventors, and generally detrimental to the public administration. They considered it established to their satisfaction, that real injustice was frequently done to inventors, not only by neglect and procrastination in dealing with their claims, but also by the undue preference of other conflicting claims urged by officers of the different departments. Without entering into the merits of any case in point, it appeared beyond doubt that the practical judges of the inventions have been very often rival inventors within the departments. Your Committee feel that, if in every case officials appointed to investigate new inventions were required to affix their signatures to their reports, very beneficial results would follow, as the personal responsibility thus attaching to them would ensure their full attention, and deter them from rejecting hastily, or on insufficient grounds, any proposition or invention brought before them. The Committee consider their report would be incomplete if they did not call attention to an Act for preserving secrecy in the case of inventions connected with warfare. The Act is the 23rd Vic. cap. 13.

As night signalling at sea in the Mercantile Marine is practically non-existent owing to the difficulties attending the use of the "flashing" and other codes, for the present I consider it more profitable to direct my attention to commercial vessels, and to the use of the signals on land, for advertising and other purposes, where the "shoregoing" public can form its opinion as to whether there is "the slightest chance of its ultimate success."

Mr. Bacon will, I hope, excuse me if I remark that in ignoring the fact that my A B C system (in which the letters of the alphabet and numerals are, by the simple pressure on keys, presented to the observer) used with the naval private signal book provides absolute secrecy, he is doing me scanty justice. Reverting to the want of an accurate speed and distance measurer supplied by my electric log, and to other of my inventions, I may state that had fair treatment been accorded me, naval officers would not have so frequently laid themselves open to being placed in the category of "shoregoing" people as some have through the stranding of H.M.'s ships.

In proof that I am not alone in my opinion of naval management, permit me to quote Chief Engineer Isherwood, U.S. Navy (*Journal* of the American Society of Naval Engineers, August, 1892):—"Millions upon millions are now spent on vessels, which, for want of the necessary direct experimental information, have to be designed largely by rule of thumb and the imagination, because those who control the navies have neither the technical knowledge to properly direct, nor the judgment to sink pride of position and accept the guidance of those who have. The man who does not know, and does not know that he does not know, will not permit the man who does know, and knows that he knows, to direct his presumptuous action."—Yours, &c.,

C. E. KELWAY.

London, October 5, 1892.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am sure that you have far more important demands on your valuable space than a continution of a discussion that, even at the early period of the third letter, has wandered from the main question, and become more a comparison of persons than facts. Still I must ask you to allow me to correct one or two points in Mr. Kelway's letter of the 5th inst.

In the first place, I have never thought fit to call into question the value of Mr. Kelway's A B C system, which I have never seen worked, and therefore it is impossible for me to form an accurate opinion of. But what I do call in question is the only advantage that Mr. Kelway advanced for it over our present system, viz., that "the mere fact of the signals being readable by uninitiated persons, as demonstrated to thousands at the above-named places, stamps the invention as one deserving the serious consideration and support of all interested in the important subject of night signalling." Now, Sir, this is the only advantage claimed by Mr. Kelway in his letter. Let him refer to it and see. I do not say that the system may not have many others besides, but this is the one he selected for his purpose, and it is this selection that led me to the opinion that "he had totally mistaken the signalling requirements of the Navy." I have done Mr. Kelway no injustice in saying that this particular advantage is not required, and pointing out that it may in cases be objectionable, The veriest tyro in signalling knows that, given a method of making distinctive signals, any *code* may be used; if a *code* be employed the advantage claimed is largely lost. The "Baconian Theory" is most useful, as by its light much may be read between the lines in the latter part of the letter. If any reader of this discussion cares to revert to my letter of the 30th ult., and compare the eight deductions from it, I think they will notice a distortion much to be regretted in any fair discussion. Nos. 1, 3, 4, 5, are legitimate, but 3 and 4 distorted. No. 2 is untrue, since the sentence has been altered from "*read by every casual observer*" to "*easily read*," two very different things. No. 6 should read "if presented to the Admiralty *and there is any chance of its ultimate success.*" The sneer about the permanent official is Mr. Kelway's. No. 7 is again unfair and should read, "It is the exception for shoregoing people to have any real knowledge of life or the conditions that surround life at sea." To insert "other than naval officers," when I was speaking generally of the sea, and not particularly of the Navy, is, in my opinion, to deliberately misquote, so as to be able to indulge in the luxury of a sneer. No. 8 should have conveyed the meaning that deliberation is required to make certain that new systems are real improvements, before the expense of introducing new systems in ships is undertaken.

Now, Sir, considering the bias of these quotations, the remainder of the letter is to me but the wail of the disappointed inventor. The Admiralty and naval officers are viewed through the lens of disappointment, and even our ships appear to be run ashore, not through tide or errors in judgment, but because they only use the harpoon and cherub log in conjunction, instead of trusting solely to Mr. Kelway's. One man is with him in this general mud throwing, for it is nothing more; and I would like to recommend part of his dictum to any reader, and ask him, with regard to the requirements of the Navy, which of the two, Mr. Kelway, or the average naval officer, is the man who does not know, and does not know that he does not know.

Digitized by Google

I can only join issue with Chief Engineer Isherwood in lamenting that the man who does not know, and does not know that he does not know, will not permit the man who does know, and knows that he knows, to direct his presumptuous action. Who is who I leave to your readers.

Sir, I must apologise for the space I have occupied, but I shall not in the future further trespass on your columns on a subject made barren of interest by the fertility of the personality it has given rise to. I can only wish Mr. Kelway every success in his invention, and assure him of my conviction that if tried in the Navy its practical utility to us will be accurately assessed.—Yours, &c., R. H. Bacon, Lieut. R.N.

H.M.S. "Vernon," Portsmouth.

PRINTERS' MATHEMATICAL SYMBOLS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Prof. Silvanus Thompson invites suggestions for an easily-printed symbol to represent the exponential a^n. Would not $a \backslash n$ serve this purpose? In the example he gives, $A\epsilon^{-ax}$, there would be an ambiguity in writing it simply $A\epsilon \backslash -ax$, but it might be written indifferently, $A\epsilon \backslash (-ax)$, $A\epsilon \backslash -a.x$, or $A\epsilon \backslash -ax$; the last I should prefer if it can be easily set up by the printer, as most clearly showing what is intended.

I do not wish to criticise Prof. Thompson's own suggestion, but what your printer has set down, $A\,exp\,[-ax]$ can hardly be what he intended. The ϵ has disappeared altogether.—Yours, &c., Chas. T. Mitchell.

Lincoln's Inn, Oct. 13.

[This letter is referred to in our Notes.—Ed. *E.*]

ELECTRICAL RESISTANCE AND MAGNETIC PROPERTIES AT LOW TEMPERATURES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The experiments of Profs. Dewar and Fleming on electrical resistance at low temperatures have an indirect as well as a direct interest.

It has been observed in the case of iron and nickel that the temperature coefficients of resistance are much greater below the temperature at which the substances change from the magnetisable to the non-magnetisable condition than above that temperature. In the case of iron the coefficients are 0·019 and 0·007. If any such change occurred in the temperature coefficient, of copper for example, at a temperature sensibly above −197°C., Profs. Dewar and Fleming could have detected it. We may therefore infer, with considerable probability, that copper and platinum are not magnetisable at any temperature much above −197°C., and that gold, silver, aluminium and tin are not magnetisable at any temperature much above −182°C. The inference is important, as Faraday and others since his time have thought it probable that non-magnetisable metals might become magnetisable at a sufficiently low temperature.

It would be interesting to know the resistances of an alloy of iron and 12 per cent. of manganese at very low temperatures. If this material behaves like nickel-steel we should find that after cooling it would be magnetisable not only at the low temperature but at higher temperatures; also, that after cooling, the resistance at any temperature below a certain temperature would be less than the resistance at the same temperature before cooling. I have found that this material remains non-magnetisable at a temperature of about −100°C. Below that I have not the means of cooling.—Yours, &c.,

London, October 13, 1892. J. Hopkinson.

TRADE NOTES AND NOTICES.

Tenders Invited.—The Corporation of Wolverhampton invite tenders for constructing works for the supply of electricity to the central portion of the borough. Specifications and plans of the area to be lighted will be forwarded on receipt of £2. 2s., which is returnable if a *bonâ fide* tender is sent in. Tenders must reach Mr. Horatio Brevitt, town clerk, by 5 p.m. on Tuesday, November 15th. Further particulars appear in our advertisement columns.

Tenders Invited.—The Corporation of Southport invite tenders for the supply and erection of an electric generating plant at the central station, Crowlands, and for cables for the mains. Tenders can be sent in for the whole or for part of the various sections, which are set out in our advertisement columns. Specifications can be obtained of Mr. J. Davies Williams, town clerk, Southport, and tenders must be delivered not later than November 14th.

——— The Directors of the Belfast Central Hotel Company (Limited) invite tenders for the supply and erection of an electric light installation in their hotel premises, Royal-avenue, Belfast. The installation is to consist of two dynamos and from 500 to 700 incandescent lamps, and to be with or without additional arcs. Some particulars are given in our advertisement columns, and all further information and copies of specification can be obtained from the Directors. Plans can be inspected at the offices of Mr. Samuel Stevenson, 83, Royal-avenue, Belfast, and tenders must be sent in by the 28th inst.

——— The Dundee Gas Commissioners are prepared to receive tenders for the supply of a switchboard, instruments, &c., for their central lighting station. Tenders by the 22nd inst.

——— The Sutton Local Board invite tenders for lamps for the public lighting of their district by gas or other illuminant for one year. Tenders to be in by the 19th inst.

Tenders Accepted.—Messrs. Hammond and Co. have secured the contract for the erection of the new central electric lighting station for the Blackpool Corporation, which, in addition to working the electric tramway, is to provide current for lighting a portion of the borough.

——— The Portsmouth Urban Sanitary Authority have accepted the tender of Mr. T. W. Quick, of Southsea, for the erection of an electric lighting station in the Gunwharf-road, Portsmouth, the amount being £8,400.

Accumulator Traction.—The Electrical Power Storage Company (Limited) call our attention to the following circular letter which they are now issuing to the chief tramway companies in Great Britain, and which they consider is the best possible answer to the criticism that has lately been made on the expense for up-keep of batteries and electrical gear of tramcars:—

"We beg to call your attention to the fact that we are now prepared to negotiate for the working and maintenance of approved tram lines equipped with self-contained or storage electric cars. The terms under which such working and maintenance can be contracted for necessarily vary with local conditions, but the maximum charge would be 66 per cent. of the gross traffic receipts. You will readily note that such an undertaking should and does constitute the most effectual guarantee of perfection of service, and we shall be pleased to discuss the matter further with you at any time."

In reply to our inquiries for further information on the subject, we have received the following letter:—

TO THE EDITOR OF "THE ELECTRICIAN."

Dear Sir: I am obliged by your favour of the 10th. I quite agree that the up-keep of batteries does depend largely on the treatment by the drivers. Our maintenance of working propositions cover the supply of drivers, conductors, engineering staff and supervision, coals, repairs of steam engines and dynamos, repairs of machinery on cars, and maintenance of the batteries in satisfactory working order. It does not include the capital expenditure on the first supply of batteries; that is to say, we do not undertake to find capital for any tramway company, but merely to ensure that a proper profit is paid on the traffic, and if 34 per cent. of the gross receipts is not sufficient to maintain the permanent way, and the general secretarial office expenses of a tramway company, we do not consider that the tramway is worth our attention.

Further, we would not undertake the maintenance and working of any line where there were less than ten cars in constant running.

Trusting these particulars constitute a satisfactory answer to your query, we remain, yours faithfully,

The Electrical Power Storage Company (Limited),
Frank King, Manager.

Maquay Syndicate (Limited).—A resolution was passed and confirmed at meetings held on August 27th and September 27th respectively, that the Syndicate be voluntarily wound up, and that Mr. Thomas Rawlins, 45, King William-street, E.C., be the liquidator.

Messrs. Cox, Robinson and Co.—Mr. Arthur Thraves, accountant, of Liverpool, has been appointed trustee in the bankruptcy of this firm.

Electric Date and Time Stamp Company (Limited).—At meetings held on September 6th and October 4th a resolution was passed and confirmed that the Company be voluntarily wound up, and that Mr. J. M. Henderson, 2, Moorgate-street-buildings, E.C., be the liquidator.

Compagnie Parisienne de l'Air Comprimé.—Baron de Pefiel has been appointed Managing Director of this Company *vice* M. Victor Popp.

Digitized by Google

REMOVAL NOTICE.—Mr. F. A. Butler, mica and talc merchant, notifies us of his change of address from St. George's-road, Peckham, S.E., to Grosvenor Park-road, Hoe-street, Walthamstow, E.

MESSRS. MATHER AND PLATT (LIMITED).—This firm have just completed the lighting of the Vaudeville Theatre, Strand, by the electric light, the installation consisting of 390 16-c.p. and 10 100-c.p. incandescent lamps. The whole of the contract, including fittings, &c., has been completed in twelve days.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).—We have received from this Company a new edition of their price list of electric light wires and cables. The list has been rearranged and divided into two sections, one being devoted to vulcanised and the other to unvulcanised wires. We notice that a column has been added giving the thickness of dielectric employed, an important matter too often omitted from lists of this kind. The weights per mile are less than in last year's list. For instance, taking 7/16 wire we find a dielectric thickness of 0·056", a weight of 790lb. per mile, with an insulation of 300 megohms in Class J, as against 852lb. last year, the outside diameter remaining 0·415 as before. In class K, as is well known, an insulation of 600 megohms is attained with the same dielectric thickness and a weight of 793lb.; while in the higher class L of 5,000 megohm insulation, the same sized wire has a dielectric thickness of 0·076, and weighs 865lb. The list of concentric cables has also undergone revision. The lead-covered cables are not given in a separate part of the list, but each lead-covered class is placed alongside the corresponding braided quality. We do not find J, K, and L, therefore, on the same page; but M, being J covered with lead, comes next to J, and N next to K. This is hardly an improvement, but the additional columns would not permit J, K, and L to be placed as before on one page.

MESSRS. B. VERITY AND SONS.—As evidence of the brisk competition now going on in the electrical and allied trades nothing is more noticeable than the special attention being paid by large supply firms to the preparation and printing of their trade catalogues, and no more complete specimen of this class of publication has recently appeared than that just issued by Messrs. Verity and Sons. This large folio book of 112 pages is crowded with illustrations of boilers, engines, pumps, turbines, dynamos, mining and milling machinery, launches, accumulators, accumulator sundries, transformers, arc and incandescent lamps, measuring instruments, switches and switchboards, safety devices, wires and cables, and all kinds of electrical and engineering sundries and accessories, including a very complete selection of electro-medical apparatus. In fact nothing is wanting as an aid in the selection of a complete plant, either for lighting or power.

THE FROUD JUBILEE TESTIMONIAL.—On Saturday last, at Cloot's Restaurant, Victoria-street, S.W., a presentation was made, consisting of a silver centre-piece for flowers and fruit, a very easy chair, and a beautiful illuminated address, to Mr. J. W. Froud to commemorate the jubilee of his entrance into the works of the well-known firm of Messrs. Benham and Froud (Limited), of Chandos-street. Many of the firm's former *employés* joined with those at present employed in forming a gathering which filled a spacious saloon to its utmost capacity. Mr. Laws, one of the directors of Benham and Froud (Limited) and honorary secretary to the Jubilee Testimonial Fund, having given a brief description of the origin of the committee's proceedings, Mr. Herbert Benham, in requesting Mr. Froud's acceptance of the gifts, spoke in high terms of that gentleman's connection with the extensive business carried on at Chandos-street. Mr. Froud, with much feeling, accepted the presentation and suitably replied, after which a musical evening followed, terminating with a vote of thanks to the hon. secretary and committee.

MESSRS. EASTON AND ANDERSON.—This firm are installing the electric light at the extensive flour mills of Mr. Seth Taylor, Lambeth, London, S.E.

MESSRS. GILBERT AND CO.—This firm have secured the contract for lighting the extensive buildings occupied by Mr. W. Straker at Ludgate-hill, E.C.

MR. WALTER LEAKE.—This gentleman has in preparation plans and specifications for lighting the Gresham Hotel, Sackville-street, and Messrs. Todd, Burns and Co.'s large drapery premises in Mary-street, Dublin.

THE DAIRY SHOW.—The annual exhibition of dairy produce and accessories is, as usual, a very successful one, the only drawback to the general convenience is the absence of the electric light, the excessive heat in the galleries rendering the promenade particularly disagreeable. Only spasmodic attempts at lighting by electricity are again noticeable, notwithstanding that the report had gained credence that an extensive installation of the electric light was some time ago imminent.

ASTON.—New public baths on an extensive scale have just been completed and opened at Aston, the buildings being lighted throughout by electricity. A novelty is introduced in the first-class swimming bath in the form of two powerful side lights with reflectors fixed three feet below the water line.

BATH.—With the commencement of the winter season the Bath Electric Light Company begins an all-day in addition to an all-night service, and have commenced charging by meter instead of by contract, as formerly.

BIRR.—The subject of the electric lighting of this town came under discussion at a recent meeting of the Local Authority; but the elections being imminent it was decided to defer taking any action in the matter until the new Board had been elected.

BOWNESS.—At the last meeting of the Local Board an agreement between the Board and Messrs. R. H. Fell and Son relating to the lighting of the streets was approved, an amendent that the Board make an application for a Provisional Order failing to find a seconder.

BRADFORD.—The Markets and Fairs Committee of the Town Council, having had under consideration three tenders for the fitting up of Kirkgate Market with the electric light, decided to recommend the acceptance of the tender of Messrs. Andrews and Preece, for supplying and fixing the necessary fittings, for the sum of £1,400, which recommendation has been adopted by the Town Council.

BRIGHTON.—At the last meeting of the Town Council the report of the Lighting Committee on September 19th, and recommending the laying of a distributing main from the north gate of the pavilion to the bottom of St. James-street, at an estimated cost of £350, came up for confirmation, and was duly agreed to.

BRISTOL.—The Bristol papers announce the gradual extension of the electric light beyond the boundary originally intended to be covered, the light having been received with much favour by the tradespeople in the adjacent districts. The Electrical Committee of the Corporation have been asked to make arrangements for a considerable extension.

CHELMSFORD.—The order of the Board of Trade directs that the wires used for the electric lighting in High-street and Tindall-street, Chelmsford, should be placed underground. The work has been commenced.

EALING.—At a Local Board meeting last week complaint was freely expressed at the increase in the price of gas recently decided upon by the Brentford Gas Company, and Mr. St. John moved that a committee be formed to consider the question of introducing the electric light. The motion was carried.

EAST MOLESEY (SURREY).—A fresh proposal for lighting this district by electricity has been submitted to the Local Authority, and has been referred to the General Purposes Committee for consideration.

EXETER.—Several Nonconformist places of worship in Exeter and the district have adopted the use of the electric light, the most recent being the large United Methodist Free Church.

HAMMERSMITH.—The Electric Lighting Committee of the Hammersmith Vestry have presented their report fixing the compulsory area for lighting under the Provisional Order. A noticeable feature of the meeting was the anxiety expressed by several of the members of the vestry that the electric light might be generally obtainable.

HAWICK.—The Town Council have under consideration a scheme for lighting Hawick with electricity, at a cost of £820. The scheme, which was prepared by Messrs. Mavor and Coulson, has been remitted to a committee to consider and report.

LLANDUDNO.—It is stated that applications are to be made for the laying down of an electric tramway along the beach at Llandudno.

MULLINGAR.—At the last meeting of the Town Commissioners it was decided to communicate with the Electrical Engineering Company of Ireland as to the probable cost of lighting the town of Mullingar by electricity.

RAVENSTHORPE.—A deputation of the Ratepayers' Association of this town has waited upon the Local Board with a resolution passed at their last meeting, urging the desirability of promoting the introduction of the electric light, and calling the attention of the Local Board to the heavy price paid for gas in the district. In reply to the deputation, the Chairman of the Board stated that the matter had been before them for the past 18 months, but they had thought it best to wait until the subject of electric lighting had developed.

SUTTON (SURREY).—At the last meeting of the Local Board the clerk reported that the Electric Light Order, giving the Board the monopoly of the electric light in Sutton, had received the sanction of Parliament, and the Board was now in a position to proceed with the matter.

Digitized by Google

TOXTETH PARK.—At a Local Board meeting on Tuesday the recommendation of a special committee on electric lighting, that Mr. G. P. McMuldrow be appointed as electrical inspector at a salary of fifty guineas per annum, was confirmed, and it was announced that arrangements were being made with the Liverpool Electric Supply Company for lighting a portion of the township at a uniform rate of 7½d. per unit. The clerk was authorised to purchase certain electrical apparatus and lamp columns.

WINDSOR.—The Eton Electric Light Company (Limited) have served the usual statutory notice upon the Windsor Sanitary Authority of their intention to proceed with the opening of the streets in the borough for the purpose of laying the necessary cables for supplying the electric light. We understand the whole of the shares in the Company have been allotted.

WOLVERHAMPTON.—The Town Council had under consideration at their last meeting the Lighting Committee's report dealing with the suggested adoption of the electric light for the town. As will be seen elsewhere, the Town Council are advertising for tenders for the construction of the necessary works, an eligible site having been obtained. The report proposes that the Lighting Committee shall be a standing committee of the Town Council and that, if necessary, corporation stock shall be issued for the purpose of carrying into effect the Electric Lighting Order of 1890. The report has practically been agreed to.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

September 21, 1892.

16,903. H. H. LAKE. London. Improvements in, and relating to, electric accumulators. (F. C. Jenkins, Germany.)

16,904. J. HOPWOOD. London. An automatic switch for electric and other light applicable to a door.

16,906. R. R. HARPER. London. Improvements connected with audible telegraphs.

September 22, 1892.

16,919. J. SWINBURNE. Middlesex. Improvements in and connected with dynamo-electric machinery, alternating current motors, transformers, manufacture of ozone and oxide of nitrogen, recovery of tin from scrap, electro-plating with aluminium.

16,934. W. H. THOMPSON and R. THOMPSON. London. Improvements in volt-meters or electrical indicators.

16,948. E. DE PASS. London. A mode of and means for enabling boats to be propelled on navigable ways by electric energy. (E. Geisenberger, A. Sellier, and E. Guillemin, France.)

16,964. S. PITT. London. Insulating electrical conductors. (E. C. Davidson, United States.)

September 23, 1892.

16,980. J. J. ROBINS. Birmingham. Improvements in connections for electrical accumulators and other similar purposes.

16,997. T. G. USHER, R. USHER, and R. C. USHER. London. Improvements in electric bells.

17,004. F. D'A. GOOLD. London. Improvements in electric arc lamps.

17,022. G. WILKINSON. London. Improvements in, and relating to, the distribution of electrical energy.

September 24, 1892.

17,091. R. E. B. CROMPTON and H. J. DOWSING. London. Improvements in insulating and supporting electric wires intended to act as resistances.

17,092. R. E. B. CROMPTON and H. J. DOWSING. London. Improvements in insulating and supporting electric wires intended to act as resistances.

17,093. W. E. AYRTON and T. MATHER. London. Improvements in electrostatic measuring instruments.

17,099. H. T. BARRETT. London. An improvement in carbon electrodes.

September 26, 1892.

17,151. A. P. LUNDBERG. London. Improved "wall," "table," or floor connection for portable electric lamps.

17,160. J. E. KINGSBURY. London. Improvements in telephone switchboard apparatus. (The Western Electric Company, United States.)

17,169. C. KELLNER. London. Improvements in, or relating to, the electrolytical decomposition of metallic salts and in apparatus therefor.

September 27, 1892.

17,205. W. ALDRED. Sheffield. Continuous electric current machines and motors.

17,207. T. JOHNSTONE. Bradford. An improved ear piece for telephones.

17,209. R. H. BEST. Improvements in the slides of electric sliding pendants.

17,222. W. P. THOMPSON. Liverpool. Improvements in, or relating to, electric metal working or welding. (C. L. Coffin, United States.)

17,223. W. P. THOMPSON. Liverpool. Improvements in, or relating to, welding or working metals electrically. (C. L. Coffin, United States.)

17,224. W. P. THOMPSON. Liverpool. Improvements in apparatus for electrically heating or working metal. (C. L. Coffin, United States.)

17,225. W. P. THOMPSON. Liverpool. Improvements in the method of, and apparatus for, electrically welding metals. (C. L. Coffin, United States.)

17,226. W. P. THOMPSON. Liverpool. Improvements in the method of and apparatus for, welding or heating metals electrically. (C. L. Coffin, United States.)

17,227. W. P. THOMPSON. Liverpool. Improvements in, or relating to, electrically welding or heating metals. (C. L. Coffin, United States.)

17,242. P. A. NEWTON. London. Improvements in electro-medical appliances. (S. Hetherington-Carruthers, New South Wales.)

17,244. C. CASALONGA. London. Improvements in, or relating to, the supply of electricity to electrically propelled and controlled aerial machines.

17,246. T. J. D. RAWLINS. London. Improvements in, or connected with, electric primary batteries.

September 28, 1892.

17,287. J. HAMER. Halifax. A new or improved shield or cover for electric gas lighting purposes.

17,299. E. S. D'ODIARDI and E. S. D'ODIARDI. London. Apparatus for the inhalation of metals or minerals vapourised by means of electricity for medical, antiseptic, or other purposes.

17,304. T. AHEARN. Canada. Improvements in electric heaters.

17,321. T. AHEARN. Canada. Improvement in electric water heaters.

17,348. R. J. CROWLEY. Ireland. Improvements in, or relating to, batteries.

September 29, 1892.

17,381. J. MUIRHEAD. Glasgow. Improvements in, and relating to, telephonic instruments.

17,423. E. CHABEAULT. London. Improvements in apparatus for supplying electricity to electrically propelled vehicles.

September 30, 1892.

17,438. F. H. ROYCE, Manchester. An improved combined electro-motor and fan.

17,462. J. MEIR. Manchester. Improvements in, and apparatus for, moulding earthenware electric switches, ceiling roses, bell pushes, and the like, and forming screw threads thereon.

17,466. H. C. BULL and G. BARON DE OVERBECK. Liverpool. An improved electro-metallurgical process.

17,467. H. LEA. London. Improvements in driving sewing machines by electricity.

17,471. S. CONETER and H. NEHMER. London. Improvements in electrical motor and fan combined for filtering and fumigating the air.

October 1, 1892.

17,491. J. STEVENSON. Middlesborough. Improvements in the application of electricity to the human body.

COMPANIES' MEETINGS & REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended June 30th last, to be submitted to the thirty-eighth ordinary general meeting at Winchester House, E.C., on Wednesday, the 19th inst., at 12 o'clock :—

The revenue for this period amounted to £111,870. 4s. 4d., and the working expenses to £29,557. 6s. 10d. After providing £12,880 for debenture interest and sinking funds, and £752. 14s. for income-tax, there remains a balance of £68,680. 3s. 6d. ; to this is added the sum of £19,893 4s. 11d. brought forward from December 31st last, making a total of £88,573 8s. 5d. A quarterly interim dividend, amounting to £19,500, has been paid, and £40,000 transferred to the reserve fund, increasing that fund to £579,714. 6s. 1d.

The Directors now recommend the declaration of a final dividend of 3s. per share, making, with the interim dividends, a total dividend of 6 per cent. for the year, and also the payment of a bonus of 1s. per share, both free of income-tax, which, together, will amount to £26,000, leaving a balance of £3,073. 8s. 5d. to be carried forward. The dividend and bonus will be payable on the 20th instant.

On July 31st last the sum of £16,800 was transferred to pay off the 168 bonds of the 1884 Issue, drawn for redemption in April last. This repayment reduces the debenture debt to £111,400.

The receipts for the half-year include the sum of £1,500 dividend to December 31, 1891, on the Company's shares in the African Direct Telegraph Company (Limited).

The Western and Brazilian Telegraph Company's Santos-Chuy Section was duplicated on June 7th last, thus completing the duplication of the whole of that Company's system from Pernambuco to Monte Video, and giving a direct telegraphic service by duplicate cables between Europe and the River Plate.

The various sections of the Company's line are in good working order.

Sir Henry D. Gooch, Bart., and the Duke de Loulé retire by rotation at this meeting, and, being eligible for re-election as Directors, offer themselves accordingly. The auditors, Mr. Henry Dever and Mr. John Gane, also offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

AKESTER ELECTRIC SYNDICATE (LIMITED).—This Company was registered on October 5th, with a capital of £15,000, in 300 shares of £50 each, to carry into effect a provisional agreement, dated June 29, between William H. Akester, of 11, Ward's-avenue, Fulham Palace-road, London, S.W., electrician, of the one part, and Patrick R. Low (as agent for the Company), of the other part, for the acquisition by the Company of the patent No. 7,718, of 1892, for "Improvements in Electric Arc Lamps," to acquire by purchase, lease, licence, or otherwise, and to use, develop, and turn to account, any other patents, patent rights, inventions, machinery, appliances, and anything in any way connected with electric or magnetic appliances for lighting buildings, works, streets, &c., railway, or other carriages, for heating railway or other carriages, or buildings, for providing motive power, or for stopping vehicles or other bodies in motion ; for working railway or other signals, and for working and moving points and crossings on railways and elsewhere, and to carry on the business of electricians, electrical, and mechanical engineers, suppliers of electricity, &c. The subscribers are (with one share each) : C. T. Praed, 24, Cadogan-place, S.W. ; Lieut. A. R. Dick, Cedarlea, Surbiton, S.W. ; Charles P. Johnston, Annandale, Streatham Common, S.W. ; Francis Skipworth, Red Cottage, Harpenden ; W. H. Akester, 11, Ward's-avenue, Palace-road, Fulham, S.W., electrician ; Francis R. Hill, 116, Wandsworth-road, S.W. ; H. H. Price, 9, John-street, Adelphi, W.C. The number of Directors is not to be less than three nor more than six, the first being Charles T. Praed, Arthur R. Dick, and one other person to be nominated by the subscribers.

GENEVA SCREW AND RIVET COMPANY (LIMITED).—This Company was registered on October 4th, with a capital of £3,000, in £1 shares, to acquire and carry on the business of screw, rivet, and bolt manufacturers, mechanical and electrical engineers, electricians, &c., carried on by D. Barnett and J. A. Cooke, under the style of "Barnett and Cooke," at Colley-street, West Bromwich, Staffs.

J. R. POWDITCH AND CO. (LIMITED).—This Company was registered on October 6th, with a capital of £4,000, in £10 shares, to acquire, take over as a going concern, and carry on the business of shop fitters, electrical engineers, electric light contractors, carpenters, plumbers, gasfitters, &c., carried on under the style or firm of J. R. Powditch and Co., at 9½ Percy-square, King's Cross-road, W.C. Registered office : 16, St. Helen's-place, E.C.

SCHIELE UNION ENGINEERING COMPANY (LIMITED).—This Company has been registered, with a capital of £12,000, to acquire, take over as a going concern, and carry on the business of mechanical, electrical, and general engineers, iron and brass founders, &c., carried on by the Union Engineering Company (Limited).

TAWE FOUNDRY AND ENGINEERING COMPANY (LIMITED). — This Company was registered on October 4th, with a capital of £2,000, in £5 shares, to carry on at Llansamlet, Glamorgan, the business of mechanical and electrical engineers, machine and engineering tool makers, boiler makers, &c.

YOUNG'S REVERSIBLE NUT LOCK SYNDICATE (LIMITED) — This Company was registered on October 6th, with a capital of £12,500, in £5 shares. The objects are to acquire, develop, and turn to account a certain invention for "improvements in locking nuts on bolts used in fastening fishplates on the rails of railroads and for like purposes," and to carry on the business of ironmasters, boiler makers, steel makers, ironfounders, mechanical, electrical, and general engineers, public works, contractors, &c.

BRIGHTON AND HOVE ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to August 23rd, was filed on September 29th. The Company was registered as the Brighton Electric Light Company (Limited) on December 16, 1885, with a capital of £25,000, in £5 shares, to acquire the electric lighting works and plant at Brighton carried on by the Hammond Electric Light Company (Limited), and in consideration for the said electric works the Company issued 1,600 shares, on each of which £3. 15s. was considered as paid, to Robert Hammond. In December, 1888, the name was changed to the present title, and the capital was raised to £100,000 by the creation of 15,000 new shares of £5 each. At the time of making up, 3,000 shares had been taken up, of which 1,600 had been issued with £3. 15s. per share paid. Upon the same shares the remaining £1. 5s. had been called, and upon 1,400 the full amount had been called, the calls paid amounting to £9,000.

BUENOS AYRES ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to June 22nd, was filed on September 19th. The Company was registered on November 12, 1881, with a capital of £100,000, divided into 9,986 ordinary shares of £10 each and 70 shares of £2 each. At the time of making-up, the 70 founders' shares had been taken up, no calls being made. The present shareholders are the original signatories to the Memorandum of Association.

NATIONAL TELEPHONE COMPANY (LIMITED).—By agreements filed September 26th the National Telephone Company have agreed to give £4,675 for the telephone business of the Caledonian Telephone Company (Limited), the vendor Company agreeing to accept 935 fully-paid shares in the National Company in full satisfaction of the purchase consideration ; and the National Telephone Company (Limited) have agreed to purchase all the business, goodwill, patents, cash rights, privileges, and other property of the Western Counties and South Wales Telephone Company (Limited) (except the licence granted by the Postmaster-General in 1885) for the sum of £11,236. 17s. 4d.

PONTYPOOL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The statutory return of this Company, made up to August 11th, was filed on September 24th. The Company was registered on March 28, 1892, with a capital of £10,000 in £5 shares. At the time of making up, 280 shares had been taken up, no calls being made.

R. C. CUTTING, DOUGLASS AND COMPANY (LIMITED).—The statutory return of this Company, made up to September 22, was filed on October 1. The Company was registered on May 11, 1892, with a capital of £20,000. At the time of making up, 2,050 shares were taken up, of which 1,972 had been issued as fully paid. Upon 64 of the remainder the full amount had been called, and upon the remaining 14 shares, £2. 10s per share had been called, resulting in the payment of £327. 10s. leaving £27. 10s. in arrears.

RIVER PLATE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, made up to June 30, was filed on July 9. The Company was registered on February 7, 1889, with a capital of £500,000, divided into 49,900 ordinary shares of £10 each, and 1,000 founders' shares of £1 each. At the time of making up, 13,557 ordinary and 892 founders' shares have been taken up, of which 2,400 ordinary shares had been issued as fully paid. Upon the remaining 11,157 ordinary and 892 founders' shares the full amounts have been called resulting in the payment of £110,892, leaving £1,570 as yet unpaid.

CITY NOTES, &c.

CALLS DUE.—*Oct. 30 :* NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED), £2 on 2,998 £10 shares. *Oct. 31 :* ISLINGTON AND GENERAL ELECTRIC SUPPLY (LIMITED), £1 on 45,000 £5 shares ; NEW TELEPHONE COMPANY (LIMITED), £2 on 48,800 £10 ordinary shares.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to appoint a settling day in, and to grant a quotation to 20,000 Six per Cent. Preference Shares in this Company.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended October 9th were £859, as against £747 for the corresponding period of last year, being an increase of £112. The

Digitized by Google

total receipts for half-year amount to £11,616, against £10,621 in the corresponding period of 1891, being an increase of £995.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Board have resolved upon the payment of an interim dividend of 3s. 6d. per share, free of income-tax, being at the rate of 3½ per cent. per annum, for the quarter ended September 30, 1892, such dividend to be payable on and after the 24th inst.

MESSRS. CROMPTON AND CO. (LIMITED).—Applications have been advertised this week for £110,000 further capital, in 22,000 ordinary shares of £5 each, payable 10s. on application, 10s. on allotment, and the balance in calls of not more than £1 per share, and at intervals of not less than two months. The list closed yesterday (Thursday).

NATIONAL TELEPHONE COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to allow 1,135 ordinary shares in this Company, Nos. 447,235 to 447,434 and Nos. 453,813 to 454,747, to be quoted in the Official List.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Oct. 7, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,851.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 753.—Vol. XXIX. FRIDAY, OCTOBER 21, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The case of the Edison Electric Light Company *v.* The United States Electric Lighting Company, which has been before the Law Courts of the United States for about five years, has at last been brought to a close by a decision of the Circuit Courts of Appeal, who give Edison the full credit for having devised and made the first practicable carbon lamp. The judgment goes carefully into the state of knowledge prior to 1879, confining this, however, for the most part to American doings, for no mention whatever is made of the name of Swan. Most of our readers who take the smallest interest in the history of electric lighting are aware that Mr. Swan experimented in 1877 with carbonised paper in a glass bulb, the connection being made with platinum wires. The earliest attempts had been made in 1848, but the work was put on one side until Mr. C. H. Stearn, who was skilful in the use of the Sprengel pump, lent his assistance. The experiments were carried on almost continuously until a lecture was delivered in Newcastle in February, 1879, when true carbon glow lamps were shown. Mr. Swan, as we observed last week, did not apply for any patent until January 2, 1880.

The step from Swan's paper filaments to the really tolerable and commercial ones of Maxim was a far smaller step than from the tar-putty spiral of Edison to his bamboo lamp which was patented on September 16, 1880. Swan had hit on carbon by a kind of inspiration, based, no doubt, on his knowledge of chemistry. Edison, like Lane-Fox, began with platinum, and, thanks to the *New York Sun* and the *New York Herald*, started a craze which neither the platinum lamp nor the modification of it could support. The tar-putty filament did not probably assist matters very much, it indicated the abandonment of platinum, but Edison had made such extravagant promises, that he was bound to go on until he achieved success. The indomitable perseverance of the man was equal to the task, and the bamboo lamp proved to be an excellent one.

Although the name of Swan does not appear in the judgment of the U.S. Appeal Court, some cognisance is taken of foreign affairs, for Edison's French patent of May, 1879, is repeatedly alluded to, and reference is made to Lane-Fox's various patents. This American case was really concerned with the patents and not with mere inventions. It may be fair to say that this patent of November 4, 1879, was the first indication so far as the American Patent Office is concerned, of the use of carbon in an incandescent lamp. This has been sufficient to win the case. But Edison's really useful work was only then just beginning. The real credit due to him is for perfecting the lamp with the assistance, no doubt, of the work of others, in such details as flashing, mounting, and exhausting.

The phenomena attending the blackening of the bulbs of glow lamps have formed the subject of an interesting investigation at the Cornell University, and a description of the experiments by Prof. Nichols is given in our present issue. The chief result is that the falling off of candle-power with age is due to a change of the filament, and not, to any large extent, to absorption of light by the film formed on the glass. The fact that the film absorbs all kinds of light equally is interesting in itself.

There are only three sources from which the blackening can come—the residual gases, the jointing material, or the filament itself. That there is very little residual gas is, of course, evident, but it has been alleged that the blackening takes place to a much smaller extent in lamps which have been exhausted without the use of mercury. Mercury may then have some direct or indirect connection with the "age-coating." Whether the blackening comes out of the joint or no could be easily settled. In some lamps the joint is less thoroughly carbonised than the rest of the filament. If, lastly, the deposit is due merely to a condensation of carbon vapour volatilised from the substance of the filament, the diameter of the filament may or may not become reduced. It is not improbable that the more volatile parts are driven off first, but there is no evidence to show that old filaments are rotten or porous rather than thin. In either case the resistance would, of course, be increased, and in a certain sense the current density would remain constant. If a mere thinning takes place, as the lamps are fed at constant voltage, the current density in the filament must remain constant, the sectional area diminishing in proportion to the current.

Dr. Fleming has called attention to the fact that the filament sometimes casts a transparent shadow on the glass, the particles being bombarded in a straight line, owing to the vacuum. Prof. Nichols' curves of candle-power in different azimuths would not show any indication of this, for just at this point one side of the filament is hidden by the other, but no mention is made by Prof. Nichols of such a shadow.

According to a note in *L'Industrie Electrique* a new type of flashing light for lighthouses has been designed by M. Bourdelles, the engineer-in-chief of the lighthouse service of France. It is claimed that with 20 mm. carbons and an optical system of four panes, about two feet in diameter, a considerably better effect can be obtained than with the heavy and costly optical arrangements used in this country with carbons of 50 and 60 mm. No indication is given of the details, and the performance is estimated rather vaguely in millions of *becs*. The photometry of lighthouses is of course a very difficult matter, and the power of the lamp should be estimated independently of the optical apparatus. It is possible that a 20 mm. carbon might be made to give as much light as the 50 or 60 mm. carbons used at St. Catherine's Point, if the light-giving surface were properly utilised.

Speaking of wall-sockets, on which we have made some observations in another column, reminds us of the flexible cord which is used in connection with these fittings. Unless of really good quality and well cared for, this is likely to be a weak point in the insulation of house wiring. The rule that fuses should be fixed wherever the size of a conductor is reduced, to protect the smaller wires, is often neglected in the case of wall-sockets. The flexible wires are practically the only conductors in a house which are liable to be short-circuited, and on this account alone they ought to be well looked after. All that is wanted is a fine fuse which is sure to go before the wires can become heated. We experienced very unpleasant burns from a short circuit in a switch on a portable lamp some years ago, the flexible wires becoming red hot before the fuse went, and we heard of a similar accident only a week ago. Fuses, however, have been greatly overdone, and Mr. Preece has called attention to the absurd number of unnecessary dry joints which are thus introduced in some cases.

The flexible cords for portable lamps and pendants are commonly made up of 25 or 30 or more strands of No. 38 or 40 S.W.G., and not the least valuable part of the covering is a layer of soft cotton, beneath which pure rubber is generally to be found, A cord composed of 25 strands of No. 40 S.W.G. has only the same sectional area of copper as a single No. 23, a much smaller size than is ever used in wiring, and yet fuse wire of about No. 20 is often used, because, no doubt, it will protect the ordinary wiring, and, perhaps, because fine fuse wires are expensive. No records have yet been published, and we are not aware that experiments have been made, on the carrying capacity of these flexible wires. If any of our readers can give figures we shall be glad to publish them. The limit might be put at the current which would raise the resistance of the conductor 15 per cent., corresponding to a rise of 70 degrees Fah., or about half-way to boiling point.

The suggestion made by Mr. Duncan in our Correspondence columns for printing exponents without troublesome "leading" leaves nothing to be desired from the printer's point of view, but the vertical lines which he proposes to use do not suggest the elevation of the index. Mr. Mitchell's reversed solidus meets this objection, and, when the exponent is enclosed in brackets, this symbol might be employed with advantage.

Prof. S. P. Thompson's letter, which has given rise to this discussion, was directed to remove difficulties between authors and printers rather than to avoid trouble and expense in setting the type, but since this side of the question has been raised, it may be observed that the line or vinculum below the small type in Mr. Mitchell's alternative suggestion gives considerable trouble; quite as much, in fact, as when larger type is used and the line is specially "leaded." With regard to the use of brackets and the solidus, although this may be considered to be no alteration of the author's text, to use it without his consent might sometimes be regarded as an unwarrantable liberty.

We were rather shocked to receive from the Electropathic and Zander Institute a copy of a report by Dr. A. Harries upon Harness' belts. We received a similar report some time ago by a Dr. Tibbits, of whom we know nothing, and which, therefore, we did not trouble to notice. Dr. Harries was, however, connected with a venture which we recently described as an honest attempt to apply electrical treatment with care and intelligence, and we greatly regret to find that he has associated himself with a concern which certainly cannot be described in the same terms. A glance through the report shows, however, as might have been expected, that Dr. Harries does not commit himself.

We alluded some little time ago to the fact that the exact nature of that which we have provisionally agreed to call electricity was no longer merely a question for ingenious scientific theorising, but had occupied the attention of the Law Courts both in France and America. In the State of New York the Court of Appeal has, to speak in the language of that part of the world, "rendered a decision" exempting electric lighting companies from taxation on the ground that they are engaged in the *manufacture* of—electricity. Still more recently the question as to whether electric lighting companies are manufacturing concerns has been considered by the Supreme Court of Alabama in the case of Beggs against the Edison Electric Light and Illuminating Company. In Alabama it has been sensibly declared that it is useless to argue that electricity is "a free gift of nature gathered from the clouds"; electricity as delivered to a consumer's lamps must be deemed a product of capital and labour and indistinguishable from a manufactured article. The Court remarked, by the way, that the collection, storage, preparation for market and distribution of ice as found in nature was not manufacturing, but the production of ice by artificial means was. By analogy, we presume, an individual getting shocks from a kite would not, whilst any one doing so by means of a magneto-machine would be, a manufacturer. Again, if central station dynamos received their initial excitation from a loadstone the "free gift of nature" argument would probably be held valid.

Digitized by Google

Bath.—On the 29th ult. all the users of the electric light in Bath were supplied with meters.

Electric Traction in France.—An electric tramway on the Sprague system is to be constructed at Gênes.

The Telephone in Russia.—It is stated that the Russian Government is about to purchase the telephone system.

Bolton.—The Town Council have decided that the town shall be supplied with the electric light. The system adopted is to be also capable of running the trams.

The Fiske Range Finder.—The Elliott Cresson Gold Medal has been awarded by the Franklin Institute to Lieut. Fiske, the inventor of the Fiske electrical range finder.

Personal.—Mr. Faraday Proctor, second engineer to the Newcastle-on-Tyne Electric Supply Company, has been appointed clerk of the works to the Bristol central station. The salary is £250 a year. There were between 40 and 50 applicants.

Westinghouse Incandescent Lamp.—The Westinghouse Electric and Manufacturing Company state that they are now prepared to receive orders for their new incandescent lamp. This lamp is, of course, said not to infringe the Edison or any other patent.

Institution of Electrical Engineers.—The annual dinner of the Institution will take place on Friday, November 18th, at the Criterion Restaurant. We are glad to learn that it is intended to curtail the speeches, and to adjourn at a comparatively early hour to the smoking-room.

Hampstead Vestry.—At the last meeting of this Vestry it was decided that the London and Hampstead Battery Company should be informed that they could not be allowed to lay wires underground instead of overhead, as the Vestry had obtained their own Provisional Order for supplying electricity in the parish.

Forthcoming Books.—Messrs. Whittaker and Co. will issue next week a new work by Mr. Allsop, entitled "Practical Electric Light Fitting." The work will be fully illustrated. They expect to have ready also Part I. of Mr. Maycock's new "Elementary Manual of Electric Lighting and Power Distribution."

Electrical Communication with Lighthouses.—The Royal Commission upon Electric Communication with Lighthouses and Lightships resumed its sittings on Wednesday and yesterday. The evidence of Captain Halpin, Mr. Bedwell, and Mr. W. Smith, of the Telegraph Construction and Maintenance Company, was received.

Blackpool.—Mr. John Hesketh writes that, in our issue of October 7th, an error made by the local Press was carried forward by us. It was reported that the same dynamos would be used both for the tramway and the lighting. This, it seems, is an error. What it is intended to do is to work both the trams and public lighting from the same station.

Old Students' Association.—The annual dinner of this Association will be held on Friday, October 28, at 7:30 p.m., at the Holborn Restaurant. The reception by the President will begin at 7 p.m. Tickets (price 5s. each) may be had from any member of Committee, or on application to E. B. Vignoles, Hon. Sec., 28, Lanhill-road, Elgin-avenue, W.

Windsor.—The Windsor and Eton Scientific Society propose holding their annual *soirée* in conjunction with the inauguration of the electric lighting of the Royal Borough. The ceremony will take place in December, and it is intended that the chief feature of the evening shall be an exhibition of electrical and magnetic apparatus. Persons wishing to exhibit should apply for particulars to Dr. J. W. Gooch, 9, High-street, Windsor.

Oxford.—The lamp-posts fixed at the top of St. Ebbe's and near the Martyrs' Memorial and other places by the Oxford Electric Company were manufactured of wrought iron at Munich for the Company, with the special object of suiting the architectural character of the City. The remainder have been manufactured by the Electric Construction Corporation, of Wolverhampton. The lamp-posts are said to compare very favourably with those erected in the City.

Electrical Trade Section.—The following are the agenda of the meeting of the Electrical Trade Section which will be held this afternoon at 3 p.m. :—(1) minutes, (2) Chicago Exhibition and report of action of Chamber, (3) County Council overhead wires and correspondence, (4) London Chamber of Arbitration and action of Chamber in regard to electrical section, (5) standardising of machinery, (6) uniformity of prices, (7) foreign competition, and (8) other matters.

The New York-Chicago Telephone Trunk Line.—This much-talked-of line was experimentally inaugurated on Tuesday, and on Wednesday was opened for business, the charge for five minutes' conversation being 38s. The newspapers state that speech is distinct, though not particularly loud. The distance is 950 miles, making it the longest telephone line in existence. The London-Paris line is 311 miles in length, and the distance between Paris and Marseilles is about 450 miles.

Birmingham.—At a meeting of the General Purposes Committee of the Birmingham Corporation on Monday the principal subject discussed was the notice by the Birmingham Electric Supply Company of their intention to apply for an additional Order extending the area over which they have powers. It is understood that it was decided to postpone the consideration of the Order for twelve months. At a later stage the committee will consider whether or not they will recommend the Council to promote an Order for electric lighting on behalf of the Corporation.

The South Staffordshire Tramways.—The South Staffordshire Tramway Company made arrangements about twelve months ago for the introduction of the overhead wire system of electric traction on their lines between Wednesbury, The Pleck, Walsall, and Bloxwich. The Pleck, James Bridge, and Darlaston section will be completed in a fortnight or three weeks. It is proposed to run 14 cars. It is anticipated that towards Christmas the service will be greatly increased, and also that the new system will shortly be adopted on the Company's other lines. The generating station has been erected at James Bridge, near Darlaston. The trolley wire is carried on iron posts, at a height of 21ft. from the roadway. The pressure, which will at first be employed, is only 300 volts. Two 15-B.H.P. are fitted to each car.

Kelvinside.—As reported in our issue of September 2nd, the "feuars" of Kelvinside have taken a decided objection to the chimney of the Kelvinside Electricity Company. The secretary of the Company has recently addressed a reply to the remonstrances of the "feuars," in which he states that he is instructed by his Directors to say that the site upon which the works are to be erected was the only available site; that the plans of the works were prepared by Mr. Munro, an electrical engineer of good standing, and were submitted to and approved by Lord Kelvin and Dr. J. T. Bottomley, the consulting engineers of the Company; that the erection of a stalk was found to be absolutely necessary; that the best known appliances for the consumption of smoke will be adopted in the construction of the works; and that the works will be carried on in such a way as to be in no degree detrimental to the amenity of the district. He is also instructed to say that his Directors fully recognise that it is their duty to carry on the works in such a manner as to be in no way offensive. They have, accordingly, given instructions for 40ft. to be taken off the height of the chimney, and for the saving in the cost of building being applied towards making the chimney of a more ornamental character.

Carlow.—In connection with the note on the reported action of the Carlow Gas Company in regard to electric light consumers, which appeared on page 550 of our issue of Sept. 23rd, the following letter from the Secretary of the Gas Company, addressed to the *Journal of Gas Lighting*, will be of interest :—

SIR: In regard to your reference to this matter in the *Journal* for the 4th instant, I may say that there is no truth whatever in the statement that the Carlow Gas Company issued a circular to the inhabitants of Carlow, informing them that "any person using electric light would be at once cut off from the gas mains." No such circular was issued, or any order to that effect. A few persons using electric light, and who had ceased to use gas, were served with notice that their meters would be removed; but this they refused to allow—it being very useful to have the gas when the electric light goes out, as it does very often. For instance, it was out for half-an-hour on the 13th inst. The electric light is on only from sunset until 12 o'clock p.m. I may add that 14 out of 203 consumers have taken in the electric light on trial; and this is the extent of the success of the Electric Light Company in Carlow. Th

Digitized by Google

Carlow Gas Company are under deed of settlement, and not under Act of Parliament; and they are, therefore, in no way bound to leave meters with non-consumers, except by courtesy.

The Central Institution.—Of the 109 candidates who recently entered for the matriculation examination at the Central Institution, 73 passed, and 6 did sufficiently well to be allowed to join the College as unmatriculated regular students. In addition to these 79 thus admitted each to attend courses in all the four departments of mathematics and mechanics, engineering, physics, and chemistry, and those who, having entered in previous years, have not yet completed their course, some 40 special students have joined the advanced courses in one or more of these departments, thus bringing the total number of students at the Central Institution up to the maximum for which it was intended. On the result of this entrance examination the Clothworkers' Scholarship of £60 a year, with free education for two years and renewable for a third, was gained by W. G. Bennett, from the Bancroft School; the Mitchell Scholarship of £30 a year for two years with free education by E. W. Hummel, from the Finsbury Technical College; the Clothworkers' Technical Scholarship of £25 a year for two years at the Finsbury College, and £30 a year for three years at the Central Institution, both with free education, by W. C. Mears; and four Institute's Scholarships of sufficient value to cover the fees for three years by M. J. P. O'Gorman (from the Royal University, Dublin), W. T. Gidden (Bancroft School), and A. D. Constable and W. A. Davis (both from St. Dunstan's College, Catford). At the end of the last session the John Samuel Scholarship of £30 and free education for a third year's student was awarded to H. C. Leake, and the Siemens Medal to C. V. Drysdale.

The Commercial Accumulator.—Under this heading M. P. Vitte, engineer to the Lyons Gas Company, in *L'Industrie Electrique* for October 10th, sings, at considerable length, the praises of the Tudor accumulator as a central station auxiliary. For central station work M. Vitte is of opinion that the pasted cell is more bother than it is worth, and points out that for this purpose a high-capacity cell is not so much wanted as one which will without subsequent injury to itself yield upon an emergency currents far above the normal, and which does not require careful and minute inspection and frequent repairs. The objection that cells of the Tudor become in time *hors de combat*, owing to the positives oxidising through, is, according to M. Vitte's experience, without foundation, and he cites the case of a plate which after being eight years in work had only a ·2 to ·3 mm. layer of oxide. The capacity of the Tudor plate, although admittedly less than that of pasted plates, is not, M. Vitte points out, so low, when compared with plates of the Faure type, as one would at first sight suppose, since the plugs of Faure plates are but indifferently utilised. The Tudor battery at the central station belonging to the Lyons Gas Company has been in use for 28 months, and has needed no kind of repair. In practice, M. Vitte finds it an easy matter to obtain an average energy efficiency of 85 per cent., and thinks that even under unfavourable conditions an 80 per cent. efficiency should not be out of the question. The Tudor plates are solid lead, superficially scored, the horizontal grooves being filled with paste; after a time the paste falls off, and we have a superficial oxidation of the entire plate.

The Telephone in Switzerland.—The Geneva correspondent of the *Economiste Français* states that the increase in the number of telephone lines since the new tariff came into operation, about two years ago, has been very remarkable. Previous to that there were 61 telephone exchanges, with 6,944 stations and a revenue of about £44,000, the annual subscription being £6, with no limit to the number of conversations. The new tariff lowered the subscription to £3. 4s. (80fr.), and the result is that at the beginning of the present year there were 101 telephone exchanges, with 12,595 stations, this being equivalent to an increase of 81 per cent. The length of line is 3,225 miles. The principal exchanges are:—Geneva (2,176 stations), Zurich (1,712), Basle (1,522), Lausanne (806), Berne (753), and St. Gall (596). The new law stipulates that each subscriber shall be entitled to only 800 conversations in the course of the year, and pay a halfpenny for each one over that number, but over 78 per cent. of the subscribers kept within the prescribed limits. Although the total receipts amounted to £65,400, the expenses incurred in putting down new lines and increasing the staff were so great that the net receipts were about 4 per cent. less than in the year previous to the passing of the new law, but for all that the profit derived by the State is so large that these expenses will soon be paid off, and a surplus will be available. The development of telephone communication has, as might be expected, checked the increase in telegraphic communication, the number of telegrams showing only a fractional increase upon those of the previous year, while it is anticipated that there will this year be an actual decrease.

The Indian Telegraph Department.—The regulations, which are the outcome of the recommendations of the Public Service Commission, for the future appointment of officers in India to the superior establishment of the Telegraph Department, from the Civil Engineering Colleges of India, have, says the *Indian Engineer*, been approved by the Secretary of State. A Provincial Service recruited in India will be established, on a rate of pay differing from that of the Imperial Service recruited in England. This service will be under the leave rules of the Indian Services, Chapter XIV., and under the General Pension Rules, Part 4, of the Civil Service Regulations. In all other respects there will be no distinction between the members of this service and those of the Imperial Service. No change will be made in the pay of the Director-General or Deputy Director-General, whether belonging to the Imperial or the Provisional Service. Directors will draw Rs.1,050 monthly, Superintendents Rs.850, Rs.675; Assistant Superintendents. Rs.475, Rs.275, and Rs.225, according to their classes and grades. Recruitment for the Provincial Service will be from students of the Thomason College at Roorkee. Students from other engineering colleges in India wishing to enter the Telegraph Department will be admitted to the Thomason College for training in telegraphy. Students must be natives of India, as defined in Statute 33 Vict. The number of appointments offered will ordinarily be two and one in alternate years, but these numbers may be varied according to the requirements of the Department. Candidates will undergo a course of training for two years at the Thomason College, and they will afterwards be appointed as apprentices, on Rs.100 monthly.

Electricity Supply in Paris.—Our esteemed contemporary *L'Industrie Electrique* publishes in its issue of October 10th a map of Paris showing the areas allotted to the different Electric Lighting Companies. The first concessions were granted in Paris in February, 1889, about a month or six weeks before Major Marindin opened his Inquiry at the Westminster Town Hall, and some six months before the Electric Lighting Provisional Order Bills relating to the metropolis received the Royal assent. The Paris companies thus had a slight start of our own, but the conditions imposed upon them were more onerous. The duration of the concessions was only 18 years; there was an annual tax of 100fr. per kilometre of conduit run, and a levy of 5 per cent. on the gross receipts. At the present moment five companies and the Municipality are at work, with a total plant capacity of about 9,500 kilowatts. Each company has a V-shaped district to itself, extending from the heart of Paris, and opening outwards to the fortifications. No company has as yet been started on the south side of the Seine. Two companies employ bare copper conductors, run in cement conduits; one, armoured lead-covered cables laid in sand; one, insulated cables laid in paraffined wood blocks placed in cast-iron troughs; one, concentric cables laid in sand; the Municipality using insulated cables run along the walls of the sewers, and also insulated cables laid in sulphated wood blocks placed in cement troughs. One Company, the Société Anonyme du Secteur des Champs Élysées, proposes to distribute alternating currents at 3,000 volts; the Compagnie Edison and the Municipality have adopted the 3-wire system, the latter with accumulators; the Société d'Éclairage prefers the plain 2-wire system with accumulators; the Société du Secteur de la Place Clichy employs the 5-wire system, with accumulators; and the Compagnie Parisienne distributes current on a peculiar storage-battery sub-station system of its own. The Municipality also employs alternating currents at 2,400 volts.

ELECTROMAGNETIC THEORY.—XXXVIII.

BY OLIVER HEAVISIDE.

(*Continued from page 578.*)

§ 167. Thus, let us first abolish the intrinsic magnetisation of § 166, and substitute equivalent electric current. Here, by equivalent electric current, we mean a distribution of electric current which produces the same induction as the intrinsic magnetisation; so that if both were to exist together, the induction would be everywhere doubled; and then, if either of them were negatived, the resulting induction would be nil. That this is possible, whatever may be the distribution of inductivity, is a very remarkable property. The induction due to magnetisation is conditioned solely by the curl of the intrinsic magnetic force, and the "poles" are essentially quite a secondary matter. That is, we may vary the poles as we like, provided we do not alter the curl of the intrinsic force, without affecting the induction or the associated energy.

The question then presents itself whether this equivalence continues to hold good when the medium is set in motion past the stationary magnetisation or electric current respectively. In the circuital equation (64), put $\mathbf{h}_0 = 0$, and introduce a term $\mathbf{C}_0$ on the right side, producing

$$\text{curl}\,(\mathbf{H} - V\mathbf{Dw}) = \mathbf{C}_0 + cp\mathbf{E}, \quad . \quad . \quad . \quad (75)$$

expressing the first circuital law; whilst (65), or

$$\text{curl}\,(V\mathbf{wB} - \mathbf{E}) = \mu p\mathbf{H} \quad . \quad . \quad . \quad . \quad (76)$$

expresses the second. Now (75) only differs from (64) in the substitution of $\mathbf{C}_0$ here, for curl $\mathbf{h}_0$ there. That is, the new $\mathbf{C}_0$ and the old curl $\mathbf{h}_0$ are equivalent. We may, therefore, dismiss the idea of magnetisation, and let the source of the induction be any distribution of intrinsic electric current $\mathbf{C}_0$. With it is associated a certain distribution of induction, identical with that due to any distribution of intrinsic magnetisation for which we have curl $\mathbf{h}_0 = \mathbf{C}_0$, and the equivalence persists when the medium is moving, or when the sources are moving. Corresponding to (70) we shall have

$$\text{div}\,\mathbf{B} = 0, \qquad \mathbf{B} = \lambda\mathbf{F}, \qquad \text{curl}\,\mathbf{F} = \mathbf{C}_0/s, \quad . \quad (77)$$

for the determination of the induction in the eolotropic manner previously pursued, when the steady state of affairs is reached; subject also to the previous reservation that $\mathbf{w}$ and curl $\mathbf{B}$ are perpendicular. That is to say, the induction is affected by the motion in the same way as if the medium had its inductivity decreased from μ to μs in the direction of motion, without any change transversely, whilst at the same time the source $\mathbf{C}_0$ is effectively increased to $\mathbf{C}_0/s$.

Equations (77) are suitable when the electric currents are in planes perpendicular to the direction of motion. For instance, let there be (to take a very easy example) two parallel plane sheets of electric current of surface-density $\mathbf{C}_0$ and $-\mathbf{C}_0$ respectively. The induction between them, which is $\mathbf{B} = \mu\mathbf{C}_0$ when at rest, becomes $\mu\mathbf{C}_0/s$ when they are in motion with velocity u perpendicular to their planes. Here s is the fraction $(1 - u^2/v^2)$ as before, and the electric force accompanying the changed induction is simply the motional electric force.

There is another way of making the eolotropic comparison, namely, by employing the vector $\mathbf{f}$ instead of $\mathbf{F}$. Then, instead of (77) we shall have

$$\text{div}\,\mathbf{B} = 0, \qquad \mathbf{B} = (\lambda/s)\mathbf{f}, \qquad \text{curl}\,\mathbf{f} = \mathbf{C}_0. \quad . \quad (78)$$

In this way of looking at the matter we regard $\mathbf{C}_0$ as suffering no change of effective strength, whilst the eolotropic operator λ/s is such as to indicate increased inductivity (from μ to μ/s) transverse to the motion, and unchanged inductivity parallel to it. The vector $\mathbf{f}$ is the excess of the magnetic force $\mathbf{H}$ of the flux over the motional magnetic force. Inasmuch as this way emphasises the fact that the intrinsic sources are really constant, it is not without its advantages. But the idea of increased transverse inductivity is rather an unmanageable one in general, especially in the case of moving electrification.

If the sources and the medium have a common uniform translational motion, it may be seen from the general circuital equations that the steady distribution of the fluxes with respect to their sources is unaffected by the motion. That is, if we travel with the medium there is no change observable. This applies in the case of circuital sources (as curl $\mathbf{h}_0$ above), as well as divergent sources (as of electrification). The naturalness of the result is obvious, when the relativity of motion is remembered.

§ 168. It is now necessary to leave these special cases of eolotropy for fear of being carried away too far from the main subject, which is, the nature of linear vector operators, in termination of this chapter on vector analysis. Up to the present only the symmetrical operator has been under consideration. Three rectangular axes are concerned, each of which is identified with parallelism of the force and flux, or of a vector and a linear function thereof. Now, if we associate the algebraical ratio of the force to the flux with the three directions of parallelism, we see that the symmetrical linear operator depends upon three vectors. If they were arbitrary, this would involve nine scalar specifications; but, being coperpendicular, there are really only six independent specifications; and, moreover, if we transform to any other system of axes (independent or non-coplanar) there can still be no more than six independent data.

But it is easy to see that the general linear vector operator must involve nine scalar specifications, viz., three for each of the three independent axes of reference that may be chosen. Thus, let $\mathbf{D}$ be *any* linear function of $\mathbf{E}$. We must then have, in terms of the $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ components, the following set of equations:—

$$\left.\begin{aligned} \mathbf{D}_1 &= c_{11}\mathbf{E}_1 + c_{12}\mathbf{E}_2 + c_{13}\mathbf{E}_3, \\ \mathbf{D}_2 &= c_{21}\mathbf{E}_1 + c_{22}\mathbf{E}_2 + c_{23}\mathbf{E}_3, \\ \mathbf{D}_3 &= c_{31}\mathbf{E}_1 + c_{32}\mathbf{E}_2 + c_{33}\mathbf{E}_3, \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (79)$$

where the nine c's may have any values we please. The axes of reference are perpendicular only for convenience; any set of three independent axes may be used, with nine properly determined c's to match. The relation between the vectors $\mathbf{D}$ and $\mathbf{E}$, which is fully exhibited in (79), may be conveniently symbolised by

$$\mathbf{D} = c\mathbf{E}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (80)$$

where c is the general linear operator.

If we exchange c_{12} and c_{21}, &c., in the set (79) we shall usually change $\mathbf{D}$, of course. Let it become $\mathbf{D}'$. It is then fully given by the set

$$\left.\begin{aligned} \mathbf{D}'_1 &= c_{11}\mathbf{E}_1 + c_{21}\mathbf{E}_2 + c_{31}\mathbf{E}_3, \\ \mathbf{D}'_2 &= c_{12}\mathbf{E}_1 + c_{22}\mathbf{E}_2 + c_{32}\mathbf{E}_3, \\ \mathbf{D}'_3 &= c_{13}\mathbf{E}_1 + c_{23}\mathbf{E}_2 + c_{33}\mathbf{E}_3, \end{aligned}\right\} \quad . \quad . \quad . \quad (81)$$

and these relations between $\mathbf{D}'$ and $\mathbf{E}$ may be symbolised, like (80), by the single equation

$$\mathbf{D}' = c'\mathbf{E}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (82)$$

The manipulation of sets of equations like (79) and (81) is lengthy and laborious. By the use of the linear operators, however, with proper attention to the laws governing them, the vectors may be manipulated with facility. Thus, to give the first and easiest example that presents itself, we may *instantly* turn $\mathbf{AB}$ to $\mathbf{A}cc^{-1}\mathbf{B}$. This is obvious enough, inasmuch as the operation indicated by c^{-1} will be precisely cancelled by the operation c, so that $cc^{-1}\mathbf{B} = \mathbf{B}$. But there is much more in it than that. For $\mathbf{A}cc^{-1}\mathbf{B}$ is not merely the scalar product of the vectors $\mathbf{A}$ and $cc^{-1}\mathbf{B}$, that is, of $\mathbf{A}$ and $\mathbf{B}$, but is the scalar product of the vectors $\mathbf{A}c$ and $c^{-1}\mathbf{B}$, which are quite different. The vector $\mathbf{A}c$ is the same as the vector $c'\mathbf{A}$, whilst $c^{-1}\mathbf{B}$ is the vector which, when operated upon by c, gives the vector $\mathbf{B}$.

The constituents of the inverse operator c^{-1} may be found by solution of (79). Since $\mathbf{D}$ is a linear function of $\mathbf{E}$, it follows that $\mathbf{E}$ is a linear function of $\mathbf{D}$; or the E's may be expressed in terms of the D's by means of a set of equations like (79), with new coefficients instead of the c's there. Similarly as regards the inverse operator c'^{-1} belonging to (81) and (82).

The vector formed by taking half the sum of the vectors $\mathbf{D}$ and $\mathbf{D}'$ is a symmetrical function of $\mathbf{E}$, say

$$\tfrac{1}{2}(\mathbf{D} + \mathbf{D}') = \lambda\mathbf{E}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (83)$$

The constituents of λ with two equal suffixes, namely, c_{11}, c_{22}, c_{33}, are the same as those of c and of c'. But the other

Digitized by Google

constituents are half the sum of the corresponding ones of c and c'; for instance $\frac{1}{2}(c_{12}+c_{21})$ in place of c_{12} and c_{21}. From this we see that the operator λ is its own conjugate, or is self-conjugate, making $\lambda\mathbf{E}$ and $\lambda'\mathbf{E}$ identical.

On the other hand, the vector formed by taking half the difference of $\mathbf{D}$ and $\mathbf{D}'$ is a simple vector product. By inspection of (79) and (82), and remembering the structure of a vector product, we may see that

$$\tfrac{1}{2}(\mathbf{D}-\mathbf{D}')=\mathrm{V}\boldsymbol{\alpha}\mathbf{E}, \quad . \quad . \quad . \quad . \quad . \quad (84)$$

where $\boldsymbol{\alpha}$ is the vector given by

$$\boldsymbol{\alpha}=\tfrac{1}{2}(c_{32}-c_{23})\mathbf{i}+\tfrac{1}{2}(c_{13}-c_{31})\mathbf{j}+\tfrac{1}{2}(c_{21}-c_{12})\mathbf{k}. \quad . \quad (85)$$

We see, therefore, that any linear function, if it be not already of the symmetrical kind, may be represented as the sum of a symmetrical function and of a vector product. Thus, by addition and subtraction of (83) and (84) we obtain

$$c\mathbf{E}=\mathbf{D}=\lambda\mathbf{E}+\mathrm{V}\boldsymbol{\alpha}\mathbf{E}, \quad . \quad . \quad . \quad . \quad (86)$$

$$c'\mathbf{E}=\mathbf{D}'=\lambda\mathbf{E}-\mathrm{V}\boldsymbol{\alpha}\mathbf{E}. \quad . \quad . \quad . \quad . \quad (87)$$

That is, in terms of the operators alone,

$$c=\lambda+\mathrm{V}\boldsymbol{\alpha}, \quad . \quad . \quad . \quad . \quad . \quad (88)$$

$$c'=\lambda-\mathrm{V}\boldsymbol{\alpha}, \quad . \quad . \quad . \quad . \quad . \quad (89)$$

where c (and therefore c') is general, whilst λ is symmetrical.

The vector $\boldsymbol{\alpha}$ is quite intrinsic, and independent of axes of reference. The symmetrical operator λ involves six scalars, the vector $\boldsymbol{\alpha}$ three more, thus making up the full nine.

Notice, by (86), (87), that

$$\mathbf{E}c\mathbf{E}=\mathbf{E}\lambda\mathbf{E}=\mathbf{E}c'\mathbf{E}, \quad . \quad . \quad . \quad . \quad (90)$$

or the scalar product of the force and the flux does not involve the vector $\boldsymbol{\alpha}$ at all.

§ 169. Now go back to the equations (79). Observe that the right members, being the sums of three pairs of simple products, are themselves scalar products. Thus, let three new vectors defined by

$$\left.\begin{aligned}\mathbf{c}_1&=\mathbf{i}c_{11}+\mathbf{j}c_{12}+\mathbf{k}c_{13},\\ \mathbf{c}_2&=\mathbf{i}c_{21}+\mathbf{j}c_{22}+\mathbf{k}c_{23},\\ \mathbf{c}_3&=\mathbf{i}c_{31}+\mathbf{j}c_{32}+\mathbf{k}c_{33},\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (91)$$

be introduced. Then we see that equations (79) are simply

$$\mathbf{D}_1=\mathbf{c}_1\mathbf{E}, \qquad \mathbf{D}_2=\mathbf{c}_2\mathbf{E}, \qquad \mathbf{D}_3=\mathbf{c}_3\mathbf{E}, \quad . \quad . \quad (92)$$

and, therefore, by combining them, we produce the *one* vector equation

$$\mathbf{D}=\mathbf{i}.\mathbf{c}_1\mathbf{E}+\mathbf{j}.\mathbf{c}_2\mathbf{E}+\mathbf{k}.\mathbf{c}_3\mathbf{E}, \quad . \quad . \quad . \quad (93)$$

thus proving that every linear operator may be exhibited in the dyadical form

$$c=\mathbf{i}.\mathbf{c}_1+\mathbf{j}.\mathbf{c}_2+\mathbf{k}.\mathbf{c}_3, \quad . \quad . \quad . \quad . \quad (94)$$

whether it be symmetrical or not. The conjugate operator is, similarly,

$$c'=\mathbf{i}.\mathbf{c}'_1+\mathbf{j}.\mathbf{c}'_2+\mathbf{k}.\mathbf{c}'_3, \quad . \quad . \quad . \quad . \quad (95)$$

where the accented vectors may be obtained from the unaccented given in (91) by changing c_{12} to c_{21}, &c., just as $\mathbf{D}'$ was got from $\mathbf{D}$, in fact.

It is now easily to be proved that

$$c\mathbf{E}=\mathbf{E}c', \qquad \mathbf{E}c=c'\mathbf{E}, \quad . \quad . \quad . \quad (96)$$

that is, if we wish to remove an operator from before to behind a vector, we may do so by simply turning the operator to its conjugate; that is, by putting on the accent, or by removing it if already there. It will, of course, be understood that when a vector $\mathbf{E}$ follows c, and we use the dyadical form of c, as in (94), it is only the three second vectors that unite with $\mathbf{E}$; whereas, if $\mathbf{E}$ precedes c, it is the first vectors in c that unite with it. Thus:—

$$\mathbf{E}c=\mathbf{E}\mathbf{i}.\mathbf{c}_1+\mathbf{E}\mathbf{j}.\mathbf{c}_2+\mathbf{E}\mathbf{k}.\mathbf{c}_3, \quad . \quad . \quad . \quad (97)$$

$$c'\mathbf{E}=\mathbf{i}.\mathbf{c}'_1\mathbf{E}+\mathbf{j}.\mathbf{c}'_2\mathbf{E}+\mathbf{k}.\mathbf{c}'_3\mathbf{E}. \quad . \quad . \quad (98)$$

These are identical vectors always. In the symmetrical case, the accents may be dropped, of course; then $\mathbf{E}\lambda=\lambda\mathbf{E}$. It will be seen that the above way of writing and working dyadics fits in precisely with all the previous notation employed in the vector algebra. The dots in (94) are merely separators, not signs of multiplication. When we put on a vector, before or behind, it unites with the vectors it is *not* separated from by dots; we therefore obtain the forms (97), (98), in agreement with the principles of notation described in the early part of this chapter.

We have already pointed out that $\mathbf{E}\lambda\mathbf{F}$, where λ is symmetrical, may be regarded as the scalar product of $\mathbf{E}$ and $\lambda\mathbf{F}$, or of $\mathbf{E}\lambda$ (the same as $\lambda\mathbf{E}$), and $\mathbf{F}$. The corresponding general property is the same; that is, c being general, $\mathbf{E}c\mathbf{F}$ is the scalar product of $\mathbf{E}c$ and $\mathbf{F}$, or of $\mathbf{E}$ and $c\mathbf{F}$. But $\mathbf{E}c$ is the same as $c'\mathbf{E}$, and $c\mathbf{F}$ the same as $\mathbf{F}c'$, so we have

$$\mathbf{E}c\mathbf{F}=c'\mathbf{E}\mathbf{F}=\mathbf{E}\mathbf{F}c'=\mathbf{F}c'\mathbf{E}=\mathbf{F}\mathbf{E}c. \quad . \quad . \quad (99).$$

The operator c must be united with one or other of the two vectors $\mathbf{E}$ and $\mathbf{F}$, but it is immaterial which it is, provided we always change to the conjugate properly, as exemplified.

The same applies when there are many linear operators. Let there be three, a, b, c. Then we have, to illustrate how the transformations are made,

$$c\mathbf{E}ab\mathbf{F}=\mathbf{E}c'ab\mathbf{F}=\mathbf{E}c'a\mathbf{F}b'=\mathbf{E}c'\mathbf{F}b'a', \quad . \quad (100)$$

and so on.

We may also introduce anywhere a new operator, accompanied, of course, by the reciprocal operator; thus

$$c\mathbf{E}a\mathbf{F}=c\mathbf{E}ab^{-1}b\mathbf{F}=c\mathbf{E}ab^{-1}\mathbf{F}b'=\&c. \quad . \quad (101)$$

The above will be sufficient to show the great power gained by the use of the operators, enabling one to do almost at sight algebraical work which would, in Cartesians, cover pages.

§ 170. The following little theorem, due to Hamilton, will serve to illustrate the working of vectors, as well as another purpose, which will appear later.

Let $\mathbf{m}$ and $\mathbf{n}$ be a pair of vectors, then their vector product $\mathrm{V}\mathbf{mn}$ is perpendicular to both, by our definition of a vector product. That is,

$$0=\mathbf{m}\mathrm{V}\mathbf{mn}, \qquad 0=\mathbf{n}\mathrm{V}\mathbf{mn}, \quad . \quad . \quad . \quad (102)$$

by our definition of a scalar product, and the parallelepipedal property. Now introduce cc^{-1} betwen the V's and the vectors preceding them in (102). Thus

$$0=\mathbf{m}cc^{-1}\mathrm{V}\mathbf{mn}, \qquad 0=\mathbf{n}cc^{-1}\mathrm{V}\mathbf{mn}. \quad . \quad (103)$$

These assert (and we cannot but believe it) that the vector $c^{-1}\mathrm{V}\mathbf{mn}$ is perpendicular to the vectors $\mathbf{m}c$ and $\mathbf{n}c$, or $c'\mathbf{m}$ and $c'\mathbf{n}$; it is, therefore, parallel to their vector product. The last statement is expressed by

$$xc^{-1}\mathrm{V}\mathbf{mn}=\mathrm{V}c'\mathbf{m}c'\mathbf{n}, \quad . \quad . \quad . \quad . \quad (104)$$

where x is an unknown (or so far undetermined) scalar. Or, operating on both sides by c,

$$x\mathrm{V}\mathbf{mn}=c\mathrm{V}c'\mathbf{m}c'\mathbf{n}. \quad . \quad . \quad . \quad . \quad (105)$$

To find the value of x, we have merely to multiply (105) by a third vector, say $\mathbf{l}$. For this gives

$$x\mathbf{l}\mathrm{V}\mathbf{mn}=\mathbf{l}c\mathrm{V}c'\mathbf{m}c'\mathbf{n}=c'\mathbf{l}\mathrm{V}c'\mathbf{m}c'\mathbf{n}, \quad . \quad (106)$$

which gives the value of x explicitly, namely,

$$x=\frac{c'\mathbf{l}\mathrm{V}c'\mathbf{m}c'\mathbf{n}}{\mathbf{l}\mathrm{V}\mathbf{mn}}, \quad . \quad . \quad . \quad . \quad . \quad (107)$$

to be used in (105), which, with x thus settled, is the statement of the little (but important) theorem. The quantity x appears to depend upon $\mathbf{l}$, $\mathbf{m}$, $\mathbf{n}$. These vectors, however, enter into both the numerator and denominator in such a way that they can be wholly eliminated from x. This may be seen by expanding the numerator and denominator. In fact, x is a pure constant, depending upon the operator c alone.

In the symmetrical case we may find its value by taking $\mathbf{l}$, $\mathbf{m}$, $\mathbf{n}$ to be $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$, and the latter to be the principal axes. Thus

$$c'\mathbf{l}=c\mathbf{i}=c_1\mathbf{i}, \qquad c'\mathbf{m}=c_2\mathbf{j}, \qquad c'\mathbf{n}=c_3\mathbf{k},$$

if c_1, c_2, c_3 are the principal scalar c's. So, by (107),

$$x=\frac{c_1\mathbf{i}\mathrm{V}c_2\mathbf{j}c_3\mathbf{k}}{\mathbf{i}\mathrm{V}\mathbf{jk}}=c_1c_2c_3, \quad . \quad . \quad . \quad (108)$$

the continued product of the principal c's.

Digitized by Google

In the general case we may put, as we know,

$$c = \lambda + V\mathbf{a}.$$

Using this in (107), on the understanding that c_1, c_2, c_3 are the principals of λ now, we shall get, similarly,

$$x = c_1c_2c_3 + \mathbf{a}\lambda\mathbf{a}, \quad . \quad . \quad . \quad . \quad (109)$$

which it will be a useful exercise to verify.

Since c is any linear operator, (105) remains true when for c we substitute its conjugate c', producing

$$x'V\mathbf{mn} = c'Vc\mathbf{mc}\mathbf{n}, \quad . \quad . \quad . \quad . \quad (110)$$

where x' is got from the expression for x by changing c' to its conjugate c. But c and c' only differ in the changed sign of $\mathbf{a}$, as in (88), (89). On the other hand (109) contains $\mathbf{a}$ quadratically, so that a reversal of its sign makes no difference. Therefore, x' is the same as x, which might not have been anticipated at the beginning of the evaluation.

(To be continued.)

SOME ANOMALIES IN DYNAMO DESIGN.*

It is frequently stated that no one can design a dynamo who is not a trained engineer. If this be the case, dynamos must be in rather a backward state, for very few dynamos are nominally designed by engineers. On the other hand, an eminent and very successful dynamo maker has said that a "cow of average intelligence could design two bearings, and that is all the engineering there is in a dynamo." Probably the truth lies between these extremes. There is not much engineering construction in a dynamo, and in most cases the machine bears the name of this or that electrician, while all the engineering details are worked out by experienced draughtsmen, who get little or no credit for their work.

Some years ago the complaint was made that dynamos were mechanically bad. The armatures were mounted on wooden hubs, and the machines looked as if they had been made by an optician. Now we are going to the other extreme. In order to appear "a thoroughly mechanical piece of work," a dynamo is made with a ton or two of extra cast-iron, parts having stresses in pounds, but made heavy enough to stand pulls of many tons. The most serious forces in a dynamo are the magnetic pulls of the fields on the armature or on one another, but these receive very little attention. Few dynamos are designed to take these pulls fairly, and their value in pounds or tons is very seldom worked out. The air space in many dynamos decreases visibly when the field is excited. Still, these pulls are steady, and not intermittent, so little harm is done, though badly designed machines have come to grief from this cause. The most common method of making a dynamo into a "good solid piece of engineering" is to develop its bed-plate to an abnormal extent. But the only important stresses in a dynamo are internal; the motion is steady, and the other forces in the machine are insignificant. It is, therefore, unnecessary to mount the machine on an extensive substructure of hollow cast iron work. Many modern dynamos look as if their designers thought they would bend unless carefully secured to good solid foundations of rock by means of ample castings capable of withstanding the enormous stresses derived, presumably, from the belts or ropes. The illusion is generally entirely spoilt by hoisting the whole thing on to two little slides, so as to admit of tightening the belt. There are many odd sights in electric stations and installations, but few are stranger than a dynamo with a ponderous bed-plate mounted on foundation rails. If the machine is designed to be used on foundation rails the bed-plate might be omitted, and full provision made for the dynamo to rest on the foundation rails, but it should not look as if it were trying in vain to sit down upon a large area, but could not reach the ground. If a casting is needed to form the framework of the dynamo, it should be arranged as a frame, and not as a bed-plate, and it might be designed much in the same way as the entableture of a paddle-wheel engine.

Any good impression that might be made by the imposing amount of cast-iron in a modern dynamo is sadly weakened by the eyebolt with which an electrical engineer always crowns his work. The eyebolt suggests that the dynamo may break down at any instant, and can be whisked off—if such an expression can be used without disrespect to the bed-plate—and replaced by another at a moment's notice. The electrician's eyebolt is almost unique. Cylinder covers, piston rods, and other parts of marine engines have eyebolts; but they are inserted and taken out by hand when the vessel comes into port. Engineers do not provide eyebolts in other cases. The boilers of a steamer, for instance, are dropped in without difficulty, and an engine maker does not send out, say, a hundred-horse stationary engine all in one piece with an eyebolt, so that it can be lifted like a dynamo or a lady's parcel. In spite of its odd appearance, the eyebolt has some advantages. But the money spent in making it, and carefully polishing it all over—a most essential process it would seem—can hardly be saved in reduced cost of carriage due to ease of lifting in those cases where sufficiently powerful cranes are in use.

The windings, except in rare cases, are left exposed. Sometimes they are painted red. This is a survival of the days when opticians painted electrical apparatus with red sealing-wax varnish. They ought, of course, to be covered in. In America they are sometimes roped, but rope is a bad conductor of heat. Besides, a dynamo has already so much paper, cotton, vulcanised fibre, string, and other materials suggestive of postage-stamp edging and sealing-wax, that it is a pity to use rope when metal can be employed. After a few years' work most dynamos are started with oil. This is due to the design of the bearings not being thoroughly worked out. The drawing office designs a bearing, and the machine is sold, and nothing more is heard of it until the insulation breaks down, and it comes back to be re-wound; but even then nothing is attributed to the bearings. This is one of those cases—common enough in engineering—of want of touch between the makers and users of machinery.

* Abstract from an article in *Industries*.

BOOKS, &c., RECEIVED.

"The Practical Management of Dynamos and Motors." By Francis B. Crocker and Schuyler S. Wheeler, D.Sc. (London: E. and F. N. Spon.) 32 pages.

"Le Premier Réseau Français de Cables Sous-Marins." Par M. Ernest Vlasto. Extract from the *Proceedings* of La Société des Ingénieurs Civils de France. (Paris. 17 pp., with charts.)

"Street Railways: the Construction, Operation, and Maintenance." By C. B. Fairchild. (New York: Street Railway Publishing Company.) 434 pp. demy 4to.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, October 21st.

ELECTRICAL TRADE SECTION.

5 p.m. Meeting at Botolph House, Eastcheap.

WEDNESDAY, October 26th.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Papers to be read and discussed.

INSTITUTION OF MINING AND METALLURGY.

8 p.m. Presidential Address; after which, the following Papers will be discussed: (1) "Mining in the Malay Peninsula: A Field for Mechanical Appliances, Hydraulics, and Electrical Transmission of Power," by H. M. Becher; (2) "Auriferous Iron Sands and the Methods of Extracting Gold therefrom," by Lieut. W. Bassett.

FRIDAY, October 28th.

PHYSICAL SOCIETY.

5 p.m. Paper to be read: "The Determination of Critical Density, Critical Volume, and Boiling Points," by Dr. Young and Mr. Thomas, to be discussed together with the Paper on "The Laws of Molecular Force" by Mr. Sutherland, and "The Dimensions of Physical Quantities," by Mr. Williams.

OLD STUDENTS' ASSOCIATION.

7:30 p.m. Annual Dinner at the Holborn Restaurant.

SPECIAL NOTICE.

With "THE ELECTRICIAN" for October 28th will be issued a Supplement STEEL-PLATE PORTRAIT of the late CYRUS W. FIELD, Pioneer of Ocean Telegraphy.

The Portrait is a very striking one, and is engraved in the best style. A few copies will be printed on India Paper, and will be forwarded post free on roller, price 3s. 2d. per copy; ordinary copies of the Portrait, post free, 1s. 2d., or framed in Black Pillar or Brown Ornamental Frame, price 4s. 6d., carriage extra.

Prospectus of "THE ELECTRICIAN" *Series of Fine Steel-Plate Portraits (13 in all) post free on request.*

Our Issue for October 28th will complete Volume XXIX. The Index to the Volume will be published with the Number for November 4th, which commences a New Volume.

NOW READY.

Volume XXVIII. of "THE ELECTRICIAN," price 12/6; post free, 13/6, abroad carriage extra.

Cases for binding Volume XXVIII., price 2/0, post free, 2/3.

SUBTERRANEAN PARIS.

Electrical engineers are generally content to leave the gas industry alone, and to regard it as offering enough competition to keep things up to the mark, but not as a dangerous rival. The principals being fairly peaceable, strife was hardly to have been expected between the inanimate elements of their plant. No struggle could be more quiet and inoffensive than a match between two street lamps, to decide which of the two would give the better light—electric or gas. But we learn from the French journals that beneath the streets of Paris a subterranean warfare of a fierce, and indeed, madly suicidal, character has been going on for months, between the electric mains and the gas mains. More than once in this country gas has leaked out into the soil, and has wandered thence into electrical conduits, and, shocked to find itself in contact with its foe, has incontinently exploded. A paving stone or two has been lifted, and an iron cover raised. The spark which fired the gas has never been accounted for; some people, indeed, believe that sparks are quite common in electrical conduits, others speak obscurely of accumulated static discharges, or make random suggestions as to lightning flashes. As a matter of fact, any conduit does excellently well, and on the last occasion an explosion occurred in a telegraph junction box at Newcastle, and this, not even in election time. But in all these cases the gas mains came off scot free, and only indirect damage was done to the electric conductors.

Digitized by Google

In Paris, on the other hand, we read that the gas pipes have been visited with a strange disease: they break out with a plague of pitted corrosion, become honeycombed with perforations, and are bathed in corrosive secretions. Nor are the electric mains uninjured, for we learn that the stoneware conduits or troughs containing the conductors become filled with "a mass of soda and potash salts, sometimes to the extent of several kilogrammes," and "the conductors themselves, especially the negative main, are so powerfully attacked that conductors having a cross sectional area of 40 sq. mm. (about No. 2 S.W.G., or 0·28 in diameter) have been ruptured."

On the whole the gas mains have had the worst of it, and the question at once rises, "Why in France only?" We have heard of a mysterious corrosion at the back of a gas meter, and the St. James's and Pall Mall Company were accused of the damage. Investigation, however, proved that the spark seen in a switch led some timid tinker—probably well acquainted with escapes of gas—to believe that there was a serious "escape of electricity." The official inquiry left the electric company without a stain on its character. It is, perhaps, not generally known that 90 per cent. of the gas mains in Paris are made of sheet iron, varying in thickness from one millimetre to four or five millimetres for pipes of one metre in diameter. The exact composition of these pipes we are unable to give. The ambiguity of the French language, so invaluable in diplomacy, and so amusing in drama, is annoying in metallurgy. About a fortnight ago we were puzzled over "*acier de moulage*," which might have meant cast steel had it not been apparently differentiated from "*fontes*." *Cuivre jaune* and *cuivre rouge* are also generally used with looseness, and often without the adjective. In "Le Gaz et ses Applications," a most interesting book, we find that these pipes are made of *tôle plombée*. This is not the recognised term for galvanised iron, and further, they are said to be coated with *une mince couche de plomb*. We are slow to believe that a lead covering can be so easily applied. However this may be, the surface is covered with bitumen very adherent to the metal. But experience seems to have shown, experience prior to the advent of electric lighting, that these pipes are subject to rapid oxidation, although, we read, this oxidation does not produce any disadvantageous effects, unless in exceptionally damp soils. With another defect, the "*oralisation*," which might be expected, we have nothing to do. It seems, then, from the account which will be found in another column, that when these stove-pipe mains run near to leaky electrical conductors they are subject to "*perforations*." The context shows that we are not always justified in translating this by "perforations," and we have for the most part used the word pitting instead—another example of the vagueness of French technical terms. Bad corrosion seems to have been found in cast-iron mains of reasonable thickness, but before any apprehensions need be felt about the gas pipes in our own streets it would be well to inquire into the extraordinary quantity of chlorine and sundry other reagents with which the soil of Paris seems to be impregnated. The salt used for melting snow may account for it, and a theory has indeed been put forward that this becomes electrolysed into metallic sodium, which, coming in contact with water, if there is room for water among all these chemicals, suffers spontaneous combustion.

We hope that our French friends will take the "minute precautions" which are thus found to be necessary, and set in order those "secondary mains which are laid with less care, the conductors being laid through stoneware without any insulators." It is the fashion only of alternate current men to lay insulated cables direct in the ground, in this country, and no such troubles need be feared from them. The proposed remedies are of some interest, and the subject ought to be considered in connection with the earthing of the middle main of three wire systems. So far as corrosion has gone in this country, and that is but a little way, the mains themselves alone have suffered and ample warning has been given. Damage to other pipes is as yet unknown, and surely there is plenty of opportunity for inspection. The observant Londoner knows almost as much of the subterranean arrangements as he does of the surface, so many are the opportunities for examining them when the streets are "up." The concluding observations in the article on which these remarks are founded ought, indeed, to spur Mr. Ferranti, his late partner, M. Patin, and other alternate-current men in France to show, in the phraseology of our French contemporary, some of "the general and convenient applications of which alternate currents are already susceptible."

REVIEWS.

Photométrie Industrielle. By A. Palaz. (Paris: Georges Carré.)

The art of photometry has been somewhat despised both in the laboratory and in commerce. No very accurate measurements can be made, hence they lose scientific interest, while commercial testing has tended to resolve itself into an effort on the part of the Gas Companies to persuade the authorities that the gas tested is of passable quality. Under these circumstances there was no object in increasing the sensitiveness of photometric measurements. This state of things, however, has been altered by the increasing competition between gas and electric lighting, and of late years great progress has been made in perfecting all light-measuring apparatus.

Perhaps the best known English book on photometry is that of Dibdin, and in Germany an excellent little book on "Electrotechnical Photometry" has been written by Krüss, but neither of these books covers so wide a range as the present work, which is a complete and readable treatise on the subject with which it deals. Although the author occasionally indulges in mathematical writing, the great part of the book is taken up with descriptions of apparatus and experiments, the discussion of results, and explanations of various matters, which, although of importance in commercial lighting, are not yet to be found in any other work on photometry. As most of the matter has previously appeared in technical periodicals, the contents have no claim to originality; but they form a valuable summary of the work which has been published on that part of optics connected with commercial lighting.

The volume is divided into six chapters. In the first, which is short and merely introductory, the fundamental terms are explained, and reference is made to the sensibility of the eye for different colours, and to the character of the rays emitted by various well-known sources of light. The chapter concludes with a theoretical discussion of the method of getting the mean spherical candle-power of a light from observations of its candle-power in different directions. This discussion might with advantage have been postponed till a later part of the book, as it is rather long, and is only applicable to the particular case of an arc light.

The second chapter is an exhaustive little treatise on photometers. It seems to be a carefully revised reprint of an excellent series of articles published by the author some time ago in the pages of *La Lumière Électrique*. It is illustrated, as the book is throughout, by diagrams which are both numerous and clear. Critical remarks about the photometers are occasionally made, but more could advantageously be added. Many instruments are described which are only occasionally used, the length of the description being no criterion of relative importance. The Bunsen screen, and the various modes of using it, are well described, and the theory of it is given at great length; but the Joly photometer, which is equally good, though not so well known, is dismissed very briefly, less space

Digitized by Google

being devoted to it than to photometers of less importance. Other sections of the chapter are devoted to polarisation photometers, spectrophotometers, absorption and dispersion photometers, and to others of a more miscellaneous type. There is little to suggest in the way of additions to the list. Something might have been said about measurement by means of photography, and one or two of the photometers designed for astronomical purposes might have been alluded to. A more important omission is the absence of any reference to the important work of Captain Abney on colour photometry. The name of Fox-Talbot ought also to have been mentioned in connection with Napoli's photometer, described on page 53. In this instrument the light from one of the sources to be compared is cut off in a known proportion by means of a revolving shutter provided with an aperture whose area can be adjusted at will. This simple and valuable device was originally described by Fox-Talbot, and has been much used by Captain Abney in his researches. Some good photometers have of late years been designed for the measurement of illumination as distinct from candle-power. The first, we believe, was due to Weber, and the second to Mascart, but although Weber's instrument is described, no allusion is made to its use as an illumination photometer.

The third chapter deals with the vexed subject of light standards. The different forms of lamp which have been suggested are well illustrated with diagrams, some being drawn to scale and dimensioned, and the opinions of the various workers on light standards are quoted. Rather too much space is devoted to describing the absolute standard of Violle, considering the impracticable nature of the unit.

The fourth chapter is taken up with a description of the various accessory apparatus used in photometry, such as the mounting of lamps and the arrangement of benches; and the fifth chapter deals with the character of the light emitted by arc and glow lamps, the report of the Franklin Institute in 1881, and the experimental work on the efficiency and character of various electric lights, which has been carried out since that date in American and other laboratories. The work is well up to date, reference being made, for instance, to quite recent work by Prof. Nichols and Mr. Tesla. A short paragraph on the absorbing power of opal, and other diffusing globes, only exhibit the lack of information which prevails on this important matter.

The last chapter of the book is devoted to the distribution and measurement of illumination. This subject is an entirely new one in a text-book, although it has been written about in periodicals and in Papers read before learned societies. Illumination is the whole object of lighting, and it is strange that so little attention has been paid to it hitherto.

GEARING.

BY E. TREMLETT CARTER.

(*Continued from page 643.*)

Spur Gearing.

This, one of the oldest forms of gearing, is now very extensively used by electrical engineers for tractive and other motor work. Within the limits of strength of the teeth of which it is formed it is perfectly positive in its action, slipping being impossible except in those cases where the gear is not properly set. Spur gear does not, however, possess that property of so interlocking the paired parts as to prevent back running, which we saw was so useful a property of worm gear; the motion being reversible with unaltered efficiency, whatever the design of the teeth. This form of gear consists in a number of short teeth or cantilevers projecting at equal distances from the rims of two wheels, the wheels running on parallel axes at such a distance apart that the teeth of one wheel nearly reach the bottom of the spaces between the teeth of the other. It is considered inadvisable that the teeth should actually "bottom," and there is no doubt that in certain classes of work, such as traction, a clearance is necessary. The materials of which spur gear has at different times been made are cast steel, phosphor bronze, gun-metal, wrought-iron, cast-iron, wood, and vulcanised fibre; and most of these have been used for electrical work. Cast iron is a common material on account of its cheapness and of the ease with which wheels can be manufactured; but it is a brittle and unreliable material, especially where the gear is liable to jolts or shocks, and the teeth when simply cast are rough and wasteful of power. Trimmed cast-iron teeth are used with advantage in heavy slow-moving stationary gear. Cast-steel possesses almost all the desirable qualities for spur wheels; it is strong, capable of a high degree of hardness, and fairly tough; but when used in gear with the same material it has a high coefficient of friction. Gun-metal and phosphor bronze are frequently used in pinions, *i.e*, in the smaller of two wheels in gear, the larger wheel being of cast steel, this combination having a high efficiency on account of the low coefficient of friction. Wood and vulcanised fibre recommend themselves solely on account of the reduced noise with which gear of these materials will run; but, as far as electrical work is concerned, appear to have been signal failures. For some time the latter material was tried on the electric tramcars at Croydon, but was found not to be capable of standing the severe shearing action when the brakes were suddenly applied. Wrought-iron, on account of its toughness, has been tried for gear running at speeds above the usual limit; and, while the teeth of this material do not so readily strip from the wheel, the want of hardness results in rapid scraping away of the surfaces of the teeth, an effect which even case-hardening is

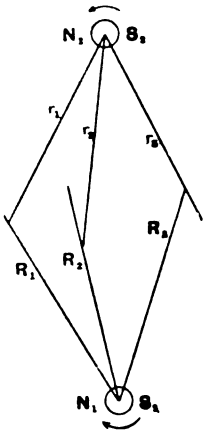

FIG. 20.

incapable of seriously reducing. In some cases the spur-wheel is cast or wrought in one piece, but in the case of the weaker materials the teeth are more frequently morticed into a frame-wheel of some stronger metal.

It would be impracticable, within the limits of such a series of articles as the present, to enter into the complicated questions of the design and construction of spur gear, the theory of which involves an elaborate mathematical treatment. It is intended to remark only upon those practical questions which affect the use of this gear by electrical engineers. Usually spur gear is employed to effect reduction of speed from a fast-running electromotor. It will, of course, be desirable that the motor, which is running at a constant rate of revolution, should produce as constant a speed in the ultimate shaft it has to drive. The gear must, therefore, act as if two smooth wheels in contact were driving one another without slipping. Such imaginary wheels conceived to be turning with the driving and the driven shafts are called the *pitch circles*. Formerly spur gearing was cast in straight, rectangular or cylindrical teeth; but it will be seen, by reference to Fig. 20, that such teeth would not produce the even motion just described. A shaft, S_1, is turning at N_1 revolutions per minute, and is driving the shaft S_2. The motion is communicated by means of a straight tooth, R, represented by a radius of the pitch circle on S_1, and by another straight tooth, r, into which it gears. Now it will be seen that when these teeth first come into gear, since the radii to the point of contact are equal, the shaft S_2 will be turned at the same rate as the shaft S_1. Not so a moment later, when the teeth are in the position shown by R_2 and r_2; for then the tooth R is at a smaller radius than r, so that the second shaft

Digitized by Google

will be turned slower than the driving shaft. And in the third position it will be seen that the second shaft will be turned quicker than the driving shaft. This crude mode of explanation may serve to emphasise the fact that unless the teeth are constructed of the proper shape there will not be a tendency to constant velocity ratio between the two shafts. Now the result of this action is to cause the driven tooth to run out of gear, and to be propelled forward till it comes into violent collision with the next tooth. For it is clear that owing to its inertia the driven shaft will resist the sudden changes in speed which the driver tends to cause; and, moving on or pressing back, will set up strains in the gearing or cause noisy collisions between the teeth.

In choosing the proportions and number of the teeth and the wheels, engineers have frequently made the assumption, correct enough according to pure theory, that two or more pairs of teeth will be in gear at the same instant. If this were practically the case, and if the gear could be relied on to retain this condition, the load would be divided between the sets of teeth in gear, so that the strength of each tooth might be designed accordingly. Now this assumption implies absolutely perfect workmanship, and that the wheels should be so accurately set and so rigidly held in place that there could be no change in the parallelism or distance between the shafts. It also implies an equal rate of wearing in every tooth. None of these conditions are realised in practice, and the probable departure from them is sufficient to make it unsafe to design teeth on the supposition that several pairs will take the load, unless a very high factor of safety is taken. It would probably be best to take a reasonably high factor of safety, and to proceed on the assumption that each pair will take the whole load during the interval that it traverses the arc of contact. Of course, having designed the teeth to have this strength, there will be no objection to their being so set that, under normal conditions of running, there will be two or three pairs in gear at any instant. These considerations affect the design of the thickness, pitch, clearance, width, and length of the teeth.

The thrust or effort on the tooth due to transmitted power is—

$$F = \frac{550\ H.P.}{v},$$

where F is the thrust in lbs., H.P. is the maximum power transmitted, and v is the velocity in feet per second at the pitch circle. This also measures the shearing stress at any point in the tooth below the point of application of the effort; but there are, in most teeth and those where the length is not inconsiderable as compared with the thickness, other stresses, arising from the bending moment of F about the root of the tooth. This bending action is the same as in a cantilever loaded at one point, the resistance to such a load being proportional to the square of the thickness, to the width, and inversely to the length between the load and the root or support. The longer the teeth, then, the greater the stresses upon the material. It will be observed that the higher the velocity at which the teeth are run on the pitch circles the less the load; but it is inefficient to run them at high speeds, because at high speeds there is more grinding or scraping between the surfaces, and greater loss of power. There is also, at high speeds, excessive wear; and the inertia being greater, there is more chattering or "back lash" between the teeth in gear. In traction work the maximum thrust, F, does not occur under the normal conditions of running, nor even when the maximum H.P. is being transmitted; for the ratio of H.P. to the speed v becomes a maximum the instant after starting commences. The starting effort is required to overcome forces which do not come into action during the normal running, and the teeth must be designed to stand this maximum thrust. In a previous communication ("On Traction," *The Electrician*, May 20, 1892) the author has shown how this maximum tractive force may be calculated. From this the maximum value of F at any point in the gearing may be obtained, for it will only be necessary to multiply the tractive force thus found by the ratio of the velocity of the car wheel rims to the velocity of the part of the gear under consideration, adding 5 or 6 per cent. to allow for gear friction.

In traction work, where considerable departure from parallelism occurs, the strength of the tooth must be designed independently of the width which the wheels will have; for it will sometimes happen that the thrust will act entirely on one corner or end of the tooth. Owing to this skewing tendency in some gears it may happen that a wide wheel is weaker than a narrow one, for with the former there is a wrench on the teeth when skewing takes place which is not found so much in the latter. It is actual experience in many instances that where teeth have stripped, and wheel after wheel has failed, the substitution of a narrower wheel has remedied the defect. For stationary work the width of gear wheels is usually about four to six times the pitch, but for traction work it would be safer to employ narrower wheels. The thickness, then, should be such that a tooth will stand the entire maximum thrust, F, at its corner, a sufficient factor of safety being taken on account of the impulsive nature of this load. A factor of 10 is usually taken for this purpose. A rule in use among English engineers gives the thickness of a tooth as:—

$$t = \sqrt{\left(\frac{30\ F}{f}\right)};$$

where f is the ultimate strength of the material in pounds per square inch, and t is the thickness in inches. A rule commonly adopted in other countries is one which is in a convenient form for general use, and is as follows, when reduced to English measures:—

$$t = k\sqrt{\frac{H.P.}{V}};$$

where H.P. is the power transmitted, V is the velocity at the pitch line in feet per minute, and k is a constant. The values of k are:—

Cast iron ..	51·4
Bronze	64·1
Hard wood	71·1

The amount of clearance which is allowed between a tooth on one wheel and the next tooth on the other wheel with which it is not in contact varies with the finish of the surfaces and the nature of the work to be done. In stationary work it is usually one-tenth of the pitch for cast wheels not trimmed, or for wheels of different materials, and one-fifteenth of the pitch for well-finished trimmed teeth. Where there is much tendency to shifting of the relative position of the shafts, however, a greater clearance should be permitted to avoid wrenching the teeth from the wheels. The pitch of the teeth will, of course, be equal to this clearance plus twice their thickness. Having determined thus much, the arc of contact and the length of the teeth may be finally decided upon. The amount of the arc of contact, that is of the arc through the geared teeth will pass in contact, depends on the velocity ratio of the wheels. If the wheels are running at very nearly the same speed, or if the ratio of their speeds does not exceed 2, the arc may be equal to about twice the pitch of the teeth; whereas, if the velocity ratio exceeds this, the angular motions of the geared teeth being so different, it will be impossible with teeth of reasonable and safe length to keep them in gear through as long an arc. In general, the length of the arc will diminish as the velocity ratio increases, the length of tooth being constant. Having determined the arc of contact at which it will be safe to run the teeth, the length of tooth may be set off. It must be remembered that long teeth are less liable to trip, *i.e.*, to jump out of gear, but are more liable to strip, and waste more power than short ones. Short teeth also hold the lubrication better than long ones, and run with less grinding and less "drop" on to one another. The usual practice is to make the tooth from two-thirds to three-quarters of the pitch in length; but it seems probable that much more satisfaction in traction work could be obtained with very much shorter teeth. It is likely that the best length for this class of work is that which is only a small fraction of an inch in excess of the length required to prevent tripping. Short teeth, narrow teeth, and fairly thick teeth seem to be the best adapted to silent, smooth, efficient, and long running in tractive work.

Two systems of reduction from that high speed at which the electromotor must run to that low speed at which it will be necessary to run the car axle have been employed, namely, the

Digitized by Google

double and the single-reduction gear. The former is the older of the two, and is in some respects superior to the other. Where it is necessary to gear from a very high speed, such as that of low-power motors, to a very low speed, such as that of the axles of town tramcars, the velocity ratio is such that single reduction involves unsatisfactory pairing between the teeth. In double reduction the velocity ratio is divided into two nearly equal factors by the interposition of a countershaft. Fig. 21 shows the double reduction gear used on the Frankfort-Offenbach tramcars. The armature shaft, running at about 550 revolutions per minute, normal speed, carries a gun-metal pinion cast with 17 teeth. This pinion gears into a cast-steel wheel, having 56 teeth, keyed to a countershaft, which thus makes about 167 revolutions; and on the countershaft there is another gun-metal pinion having 26 teeth, gearing into a 52-tooth cast-steel wheel on the axle of the car. The ultimate velocity ratio is about 6·6, and the normal speed of the car axle is about 83·5 revolutions. In this particular case the teeth do not appear to have been very carefully trimmed, for the depreciation is high. The pinions wear out in about a month, and the steel teeth last only about ten months. In Philadelphia electric cars have been running with unrenewed wheels for a very much longer time, the teeth standing a service of several hundred miles without a hitch and with little wear. The pinions in this case are of phosphor bronze, but the wheels are of the same material as at Frankfort; the teeth in each wheel were carefully trimmed and

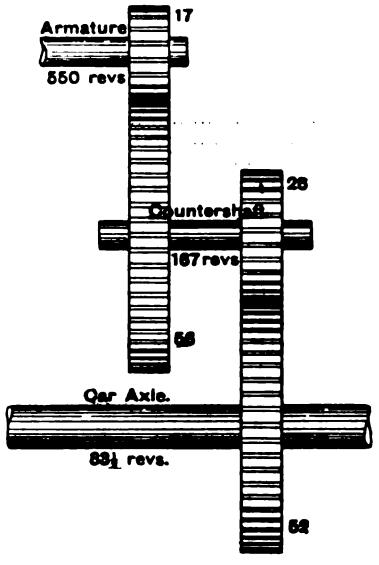

Fig. 21.

protected from road dirt. Only single reduction is effected at Philadelphia, but the velocity ratio is not so high as at Frankfort. Single reduction is suited to those cases where the velocity ratio is not greater than 2½; but beyond this figure the wheels become inconveniently large and the teeth do not properly pair. Stationary gears, such as those for coupling electromotors to pumps or cranes, are sometimes provided with a number of separate wooden teeth or *cogs*, which are fixed into a frame wheel, and easily renewed. This form of gear is also used at some water-power electric light stations. The cogs are cut and trimmed separately, and are tenoned into the frame wheel by means of wooden wedges or wrought-iron pins. Hornbeam, a white, very compact, hard, and tough British timber, capable of a very high polish, is largely used for these teeth; but Scotch beech is gradually replacing this material on account of its superior durability. Timber for this work requires to be exceptionally tough, and none but that grown on the hardest subsoils and seasoned for several years will stand the stresses on spur or bevel cog wheels.

[*Erratum.*—By an error, for which the author was in no way responsible, a three-thread worm was illustrated in Fig. 17 of his last article, instead of a one-thread worm as described. —Ed. *E.*]

(To be continued.)

A KEY TO ALL MAGNETISM.*

BY S. EVERSHED.

Given a fascinating field for research, the resources of an American laboratory, an experimenter with that faculty of patient plodding work characteristic of the Teutonic mind, and we have all the conditions for the production of a monograph almost as exhaustive (and exhausting) as Mr. Casaubon's "Key to all Mythologies." The Rev. Edward Casaubon died, we remember, before he completed his labours, leaving a widow, a mass of notes, and a "synoptical tabulation for the use of Mrs. Casaubon" behind him. Mr. Charles P. Steinmetz is wiser and more considerate of his executors; he publishes as he goes, and we have before us Part II. of his research "On the Law of Hysteresis," in the form of a Paper of some 110 octavo pages, read at the sixty-seventh meeting of the American Institute of Electrical Engineers. There are giants in America, but surely the Institute made more than one bite at such a Paper!

Setting aside its general diffuseness and somewhat inordinate length, this communication contains a large number of interesting and valuable results of a qualitative kind. In a former Paper Mr. Steinmetz had shown that for various samples of iron and steel the energy converted into heat during a complete cyclic change of induction followed the empirical law,

$$\text{energy wasted} = \eta B^{1.6} \text{ ergs},$$

and in the first chapter of the present contribution he carries his investigation many steps further by showing that this law is approximately true, not only for almost every conceivable

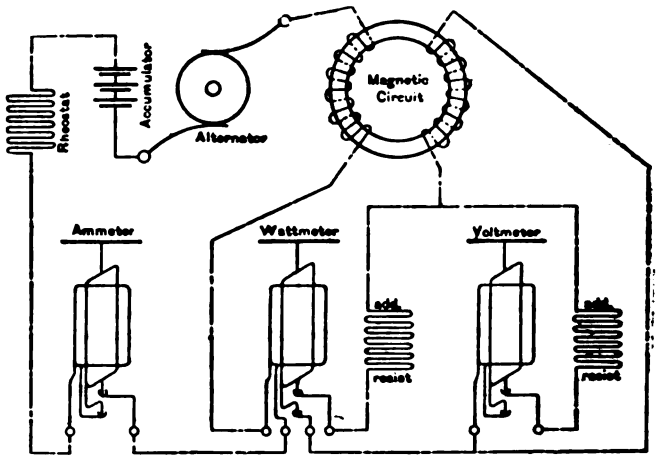

Fig. 1.

kind of magnetic material, but for cycles taken at any part of the B H curve, whether symmetrical about the origin or not.

This last result was obtained by maintaining a source of constant of E.M.F. in the magnetising circuit in addition to the periodic E.M.F. of an alternator, the power wasted being measured by a wattmeter and the induction by a voltmeter in the usual manner. Mr. Steinmetz obviated the need for corrections for C^2R in the exciting coil by coupling the pressure coil of the wattmeter to an independent coil wound along with the exciting coil. The arrangement will be clearly understood by reference to Fig. 1, which we reproduce from the Paper. These tests were made at frequencies varying from 67 to 170 periods per second. A good example of the closeness with which the 1·6th power law is followed is shown in Fig. 2, where the full line represents the empirical law; the points X are observations of loss with alternate currents only, while those marked ⊙ are observed values of loss when an alternate current is superposed on a direct current; the steady induction produced by the latter is marked in "kilolines" opposite each point. This figure contains in itself ample justification for the statement made by the author that

* "On the Law of Hysteresis (Part II.), and other Phenomena of the Magnetic Circuit." By Charles Proteus Steinmetz. A Paper read at the sixty-seventh meeting of the American Institute of Electrical Engineers, September 27, 1892.

"the energy dissipated by hysteresis depends only upon the *difference* of the limiting values of magnetic induction between which the magnetic cycle is performed, but not on their absolute values; so that the energy dissipated by hysteresis is the same as long as the amplitude of the magnetic cycle is the same, no matter whether the cycle is performed for instance between the values of magnetisation.

$$B_1 = +\ 4000 \text{ to } B_2 = -4000,$$
$$\text{or } B_1 = +\ 6000 \text{ to } B_2 = -2000,$$
$$\text{or } B_1 = +\ 8000 \text{ to } B_2 = \pm\ 0,$$
$$\text{or } B_1 = +14000 \text{ to } B_2 = +6000.$$

In either case the hysteretic loss is the same since the magnetic variation is the same, viz.: $B_1 - B_2 = 8000$; hence the general form of the empirical law is

$$\text{Hysteretic loss per cycle} = \eta \left(\frac{B_1 - B_2}{2}\right)^{1.6} \text{ ergs.}$$

In Chapter II. our author returns to magnetometer work and devotes a large portion of the 40 pages to the description of tests made on some 60 or 70 samples of magnetic substances ranging from "Norway" iron to amalgam of iron. A number of valuable notes on these various materials are scattered at random through these pages; for example, Mr. Steinmetz finds that Mitis metal is for all practical purposes magnetically "identical with ordinary good wrought iron;" again, a sample of very soft annealed cast steel is "far superior to ordinary good wrought iron, and almost approaches 'Norway' iron."

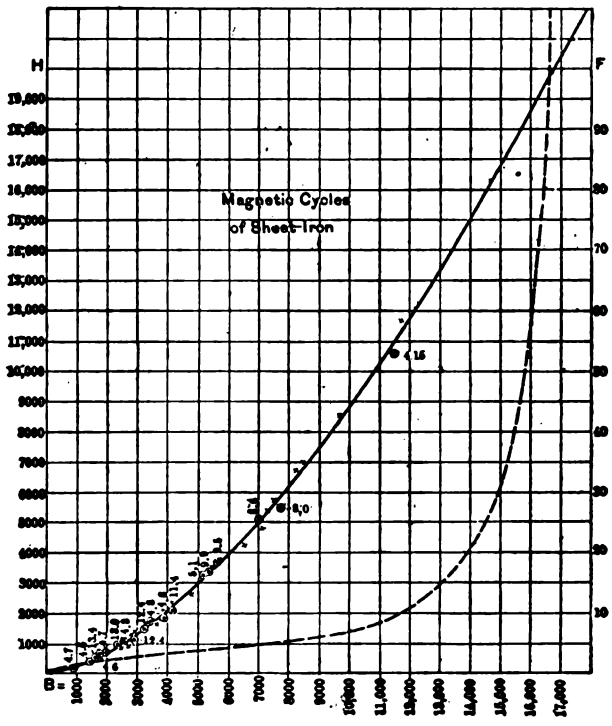

FIG. 2.

What this really means is, that its permeability is very little short of that found for "Norway" iron, while its hysteresis loss is some 40 per cent. larger—by no means an inordinate amount. We may note that cast steel of this quality is not unknown in England, and is being introduced to some extent in dynamo and motor building, in cases where somewhat complex pole pieces and frames are required. Its mechanical strength and high permeability leave little to be desired.

Perhaps the most interesting material included in these tests is the amalgam of iron obtained by electrolysing sulphate of iron with a mercury cathode. Mr. Steinmetz appears to have met with some little difficulty here. The present writer, who made some experiments on the magnetic properties of iron amalgam in 1886, found no difficulty in preparing it as rapidly as electrolytic copper, but the iron sulphate solution must be maintained as dense as possible by keeping it at about 100°C., otherwise very little iron is deposited. From this hot solution a bright deposit of pure metallic iron is readily obtained, and it is noteworthy that such iron has a larger coercive force than the best charcoal iron. The results given by Mr. Steinmetz for iron amalgam are in close agreement with those obtained by the present writer, and show a large coercive force and exceedingly small permeability. One would have expected a very small coercive force in a solution of iron in mercury, but the amalgam is, apparently, a definite crystalline alloy dissolved in more or less mecury. This chapter concludes with the tests of magnetite (loadstone), nickel, and cobalt, in the middle of which the author sandwiches a remark to the effect that "Ewing's values for hysteresis loss are the lowest ever observed on iron so far as I know." So far as we know also; in common with every designer of magnetic apparatus—from transformers to ammeters—we wish they were not quite so unique. The present writer has never found iron less than 20 per cent. worse than Ewing's "soft iron," and many samples are 40 or 50 per cent., and one sample with at least 90 per cent. greater hysteresis loss is on record.

Chapter III. is headed "Results," and the cream of them is contained in Table XLVII., which we reproduce here. In this table, as, indeed, throughout the whole Paper, Mr. Steinmetz is not content with recording the results of the tests, but continually compares them with the law of the 1·6th power for hysteresis loss, and Frölich's formula in new clothes for the relation of what the author calls metallic induction and magnetic force. Metallic induction is only another name for $4\pi I$, and is denoted in the Paper and in Table XLVII. by L. Magnetising force is measured in ampere turns per cm. (or per inch), and is denoted by F, then Frölich's formula is

$$L = \frac{F}{a + \sigma F},$$

where a is the coefficient of magnetic hardness,

σ " " " saturation,

when F is infinite L becomes $1/\sigma$, and this value is inserted in the table under L_∞. F_0 is the value of a/σ, and is evidently the value of F corresponding to $\frac{1}{2} L_\infty$. Yet another symbol is rampant in the Paper, namely, ρ—the "metallic magnetic reluctivity" or ratio $\frac{F}{L}$ and our author's pet law is contained in the statement that "beyond a certain minimum value of F, the reluctivity

$$\frac{F}{L} = \rho = a + \sigma F = \frac{F_0 + F}{L_\infty},$$

only another way of writing Frölich's formula. The hysteresis law is here given in slightly altered form—metallic induction being properly substituted for B—and we have the hysteresis loss

$$H = \eta \left(\frac{L_1 - L_2}{2}\right)^{1.6} = H_\infty \left(\frac{L_1 - L_2}{2L_\infty}\right)^{1.6}$$

where H_∞ is "the maximum value of hysteretic dissipation of energy for absolute saturation," whatever that may mean.

Mr. Steinmetz finds that these two fundamental empirical laws "hold good for all kinds of wrought and cast-iron and steel, for nickel and magnetite and most likely for amalgam of iron, hence apparently for all magnetisable materials."

We are not quite sure whether Mr. Steinmetz intends Table XLVII. to be referred to by the dynamo builder as a complete specification of every kind of iron. To our mind its chief use and interest lie in the widely differing values of a, σ and η, which—whatever be the precise meaning attached to them—clearly indicate the necessity for systematic testing of iron by every manufacturer of magnetic apparatus, in which the permeability, coercive force and hysteresis are of importance.

Better than a cloud of formulæ, more convincing than a volume of empirical mathematics, is the series of characteristic curves given in Fig. 3 (Fig. 17 of the Paper), and we give them here in the faith that they are drawn from experimental results, and not from Frölich formulæ. These curves are plotted in ampere turns per centimetre and "metallic induction"—or $4\pi I$.

The remainder of this chapter is occupied with an attempt to condense the previous results into tables giving average

Digitized by Google

values for the magnetic "constants" of the different classes of magnetic materials in common use. A glance at Table XLVII. would have been sufficient to deter any one but the author from engaging in such fruitless warfare with Nature's irresponsible lawlessness. But Mr. Steinmetz clings to Frölich throughout, and appends to each table of magnetic properties the value of the "absolute saturation" of the substance, on the assumption that Nature behaves with a due sense of decorum; thus we find the absolute saturation of "average wrought and sheet iron" given at 18,200; while that for average cast iron is calculated to be 10,500. Of course, wrought and cast iron ought to be satisfied with that, but they are not. We believe Prof. Ewing has carried the first up to 45,000, and cast iron to 16,000. The present writer has carried wrought iron as far as 23,000, and cast iron to 14,500, and our author deplores this immoral state of things in the following paragraph:—

"With regard to cast iron, I must remark, however, that some tests of Ewing and others show magnetisations as high as L = 16,000, while I was never able to reach much beyond L = 10,000. It must be assumed, therefore, that either the linear law of magnetic reluctivity, $\rho = a + \sigma F$ ceases to hold for higher magnetisation than I was able to reach—*which is not likely, however*—or we must assume that there exist kinds of cast iron far superior to all the samples I ever came across, and if so, then very great improvements are possible in the manufacture of cast iron for magnetic purposes."

Could infatuation go further? What can be done with a man who prefers to accuse American founders of casting bad iron rather than abandon a more or less clumsy empirical formula—which it is ridiculous to call a law—and which was only made to fit the facts as far as they were known. Is it possible that Mr. Steinmetz is unable to distinguish between a physical law and that miserable abortion an empirical law? Mr. Steinmetz warns ironfounders "to keep manganese out of cast iron, since manganese is known to be the enemy of all the magnetic properties." May we warn him to keep empirical formulæ out of his researches since empirics are known to be the enemy of scientific progress?

After this we have a chapter headed "Heterogeneous Materials." It is crowded with F and L and ρ and σ, of course, but the really valuable results are given as curves, in most of which actual observations are plotted. By the way, one of the heterogeneous materials is an air gap, and we are cautioned quite seriously not to take the magnetic resistance between two parallel pole faces as equal to the ratio length/area. Have Dr. Hopkinson and Prof. George Forbes no readers in America? One interesting result given in this chapter relates to a tube full of iron filings, of which the hysteresis loss was larger than could be accounted for by molecular friction, being, in fact, at least four times greater than the value for the worst sheet iron tested by Mr. Steinmetz, and he concludes that molar friction of the filings themselves accounts for some of this increased loss. When the filings were solidified into a more or less rigid mass by saturating them with paraffin wax the hysteresis loss was reduced by nearly 50 per cent.

The last chapter contains "Conclusions and Fallacies"—such fallacies, we presume, as are omitted in the earlier part of the Paper. The author believes "that the best chance to arrive at a fuller understanding of the phenomena of magnetism we shall have whenstarting in the research from the correspondence H—L. (Hysteresis loss and metallic induction.) However, this law of the 1·6th power I believe is not a *differential* law like, for instance, the quadratic law of gravitation, but an *integral* law like the law of *probability*, with which it seems to be connected in some way." Perhaps they are, but possibly the author is just a little out of his depth here; at all events, we are.

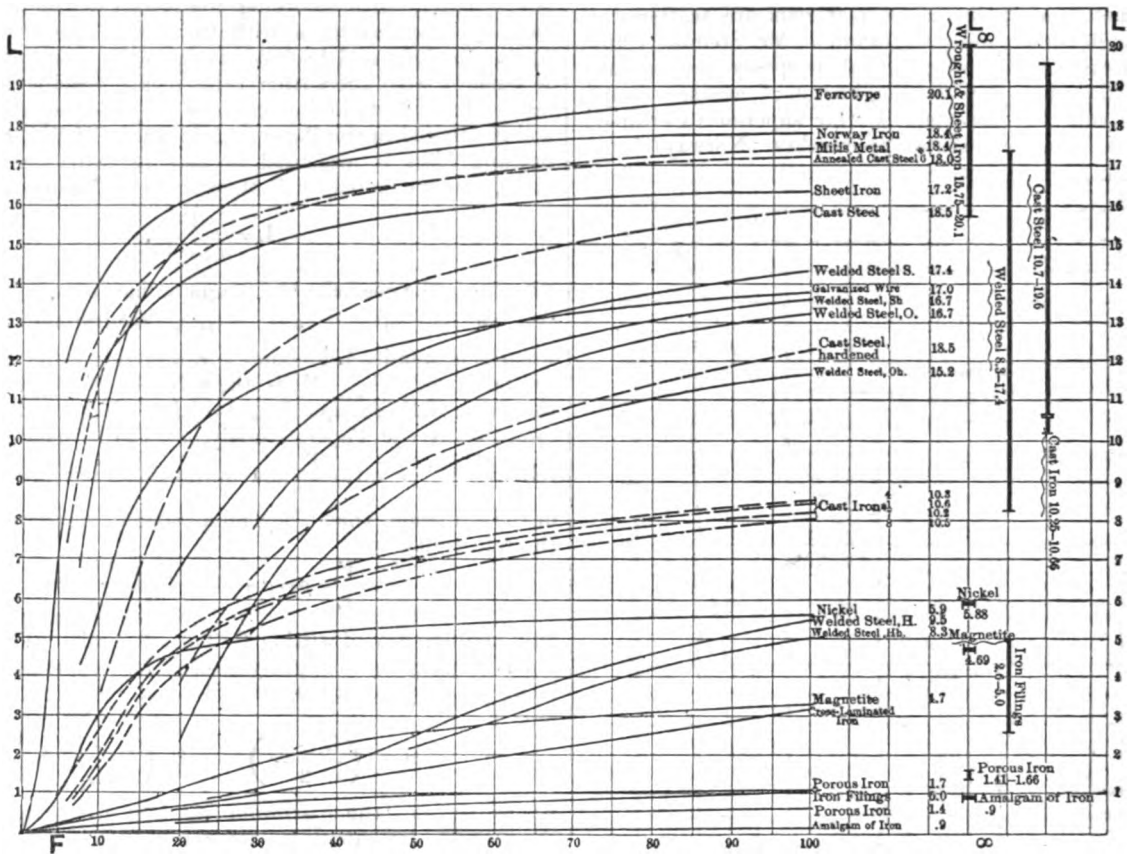

FIG. 3.

One of the fallacies attacked has reference to Ewing's magnetic model: "Ewing makes an assumption which is in contradiction to all our present knowledge of molecular physics. All the facts of the kinetic theory of gases, of thermodynamics, &c., carry to the conclusion that the *dimensions* of molecules are *infinitely* small compared with their *distances*. But Ewing supposes the distance of the centres of molecular magnets is not much greater than their length. . . ." Truly a most perfidious monster this Ewing. It seems sufficient to point out to our author first, that solid iron is *not* a gas; secondly,

Digitized by Google

that Ewing only imagines a magnetic molecule—a particle, if you like—being led thereto by the behaviour of a bunch of real little magnets. In short, the Ewing model is only an analogue of a magnetic substance, and is naturally suggestive of the real structure of such substances. It is only by grasping at such gross materialisations of physical phenomena that our spiritual eyes can catch glimpses of that "Reality behind Phenomena" which must ever be the goal of scientific research.

AN ELECTRIC BRAKE-DYNAMOMETER.

Many electromagnetic clutches and several brakes have from time to time been invented. Some of the former may come into practical use, especially in cases where it is necessary to manipulate them from a distance, and in case anything goes wrong with the electrical arrangements, a mechanical connection could generally be made. Electromagnetic brakes will probably be received with more hesitation, for a trifling derangement of a contact might lead to a failure, and a failure of a brake generally leads to a more or less serious accident. An ingenious application of an electric brake has been made by M. Pasquilini in a dynamometer for testing small torque high speed motors. A copper disc, Fig. 1, is mounted on the end of a shaft, B. This shaft is attached by a flexible coupling to the motor. An electromagnet, C, is mounted on a shaft, T, and counterpoised by a disc, V. The shaft is supported at T by knife edges, the axis of the

Digitized by Google

whole being in a line with that of the shaft B. Four pairs of pole-pieces, K, embrace the edge of the disc, which, therefore, moves in a powerful magnetic field. Eddy currents are thus set up in the copper, and the electromagnet is pulled round by what may loosely be called magnetic friction. Two graduated levers, shown in Fig. 2, are carried by the counterweight V, and by sliding weights on these the pull of the copper disc is balanced. A pointer shows the exact position of equilibrium. The measurement of the power is made as in an ordinary Prony brake.

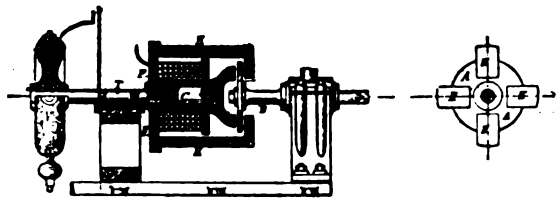

FIG. 1.—Pasquilini's Brake Dynamometer. Section.

An interesting inquiry might be made into the real function of various measuring instruments. In many cases it would be found that the displacement or indication of the instrument is only an incidental feature of the apparatus. A Prony brake is employed as a means of absorbing the load of a motor, and it dissipates the energy in the form of heat. The measurement can often be made and concluded before the pulley has become seriously heated; but if the test be continued some means of cooling must be applied. The dynamometer of M.

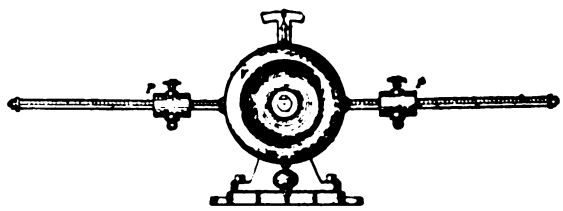

FIG. 2.—Pasquilini's Brake Dynamometer. End View.

Pasqualini effects precisely the same result, but the action is no doubt very superior to any form of friction brake, because there is no absolute contact, and therefore no jumping or binding need be feared, while the regulation of the exciting current, which need not be measured, gives perfect control of the speed. The disc might be run until it is nearly red hot without much danger or inconvenience.

ELECTRIC LIGHT FITTINGS.

In the Notes of our last issue we observed that wall-plugs and lampholders were designed on different lines, and that plugs which would fit into an ordinary lampholder were rarely, if ever, to be found in catalogues of fittings. We are not surprised to learn that such devices are to be purchased, and samples have been sent to us by the General Electric Company and by the Corlett Engineering Company, and a model has been shown us by Messrs. Evered and Co. The plugs supplied by the General Electric Company are of two patterns, one intended for use with a bayonet holder, and one for an Edison socket. These, we understand, will be included in a catalogue which will be issued by this firm next week. The plug, Fig. 1, is of porcelain, and resembles the brass cap of a lamp, except that the pins are rather longer. A screw cover protects the terminals, which are provided with round nicked nuts. A bridge of porcelain stands up between the terminals and serves, as in lampholders, to keep the stray wires apart, and to take the strain of the wires which pass through transverse holes in it. The wall-socket consists of an ordinary lampholder, in which the nozzle and cap have been replaced by a flange. A drawback to such an arrangement for wall-sockets is, that the spring plunger contacts are easily accessible when the plug is out, and, as we suggested last week, special design is needed. Any of these locking sockets might be used for ceiling roses, with great advantage in some places. This protection of the contacts would only apply where the sockets are within reach, and where they are likely to be left open. The other plug (Fig. 2) is of the Edison type. This is a favourite form with many people, and the lampholders of this pattern have certain advantages. It seems natural to find that the body of this plug is made of wood, boxwood it is true, and neatly turned but both electrically and æsthetically it is inferior to the porcelain sample; mechanically also, since there is no provision for taking the pull of the wires. It should be remembered

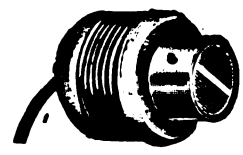

FIG. 1.

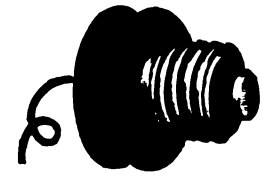

FIG. 2.

that where a wall-plug is locked into the socket, as in these cases, the flexible cord is liable to receive accidental tugs, and these, when due to an unwary person tripping over or catching his foot in the loose wires, are good for trade, especially for the art fittings department. The plug sent us by the Corlett Engineering Company consists of a small black wooden handle, about the size of a small bradawl handle. It is finished like a brass capped lamp, but the wires seem to be permanently fastened. At all events we have not succeeded in opening it.

A new wall-socket has been sent us by Messrs. Evered and Co., not in connection with our remarks about interchangeability with lampholders, for we received it before these appeared. It is very substantially made, and is itself a switch. A bayonet plug makes contact with the ring into which it fits, and an end contact when it is pushed home. We understand that in the latest form this is not a mere pressure contact of the flat spring D with the head E, as shown in the illustration, but that a spring plunger contact is provided. We are glad also to learn that the vulcanised fibre which was used for insulation in the sample sent to us has been dispensed with, since, excellent as its mechanical qualities are, this material is quite unsuitable for insulation in electric light fittings. The plug bayonets firmly into the socket, and in turning it, the switch C is moved over

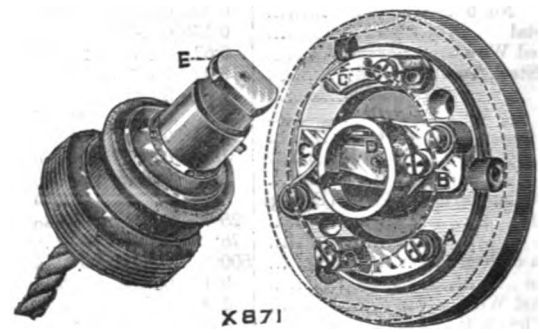

FIG. 3.

to the position G, thus completing the circuit. A cheaper form is made without the switch, and both kinds are provided with a fuse. This form of socket is much more easy to use in the dark than the common two-prong pattern; but having a single bayonet pin, it might have to be turned round a good deal before getting it fixed. Nothing can be more annoying than trying to fit a two-prong plug in an awkward position near the floor in the dark.

Among the ingenious devices brought out some seven years ago by the Vitrite Company plugs of the lampholder pattern were made. These could be used for attaching flexible wires to lampholders, or as connectors for pendants. Connectors were first made, we believe, by Messrs. Faraday and Co., about the size of an acorn, and called "acorn connectors." They were made of boxwood covered with brass cups and enabled a pendant fitting to be taken down or exchanged. We

Digitized by Google

have heard nothing of these for years past. If we are not mistaken, the Vitrite Company made a rather ugly socket into which either a lamp or a connector plug could be fitted, but the material was not suitable for use in large masses, but neither these nor the plugs appear in modern catalogues.

Attention to some of these minor fittings would help to popularise electric light in small houses where the little conveniences would be better appreciated, perhaps, than in larger establishments. One cannot have every advantage at the same time. Nothing can be more convenient as a plug than the plain concentric pattern, which will go in at once as soon as the one hole is found; but its admirable simplicity would be lost if any locking or switching device were added.

Messrs. Evered have also sent us a shadeholder, Fig. 4, for carrying large shades. By pressing together the handles A A the clips B B B are drawn towards the centre, the shade is then placed in position, and the handles are released, the spring C forcing the clips outwards, and firmly holding the shade, even if it varies from the standard size, and whether made with or without a lip. No set screws are used in this

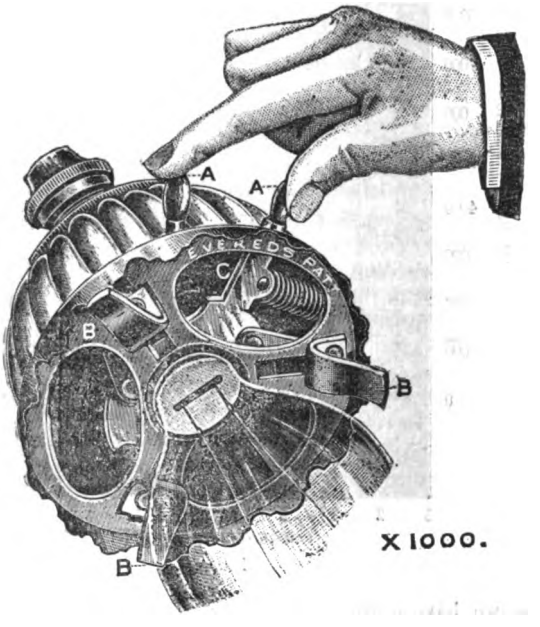

Fig. 4.

holder, and the brass dome, which is made as in the illustration, or with perforated ornamentation, fits between the usual shadeholder rings on ordinary lampholder.

ON JOINTS IN MAGNETIC CIRCUITS.*

BY PROF. EWING, F.R.S.

In the *Philosophical Magazine* for September, 1888, an account was given by Mr. William Low and myself of experiments we had made to examine the influence of a plane of transverse section in an iron bar which formed part of a magnetic circuit. It was found that a transverse cut introduced what is now frequently spoken of as magnetic resistance, even when the faces at the cut were scraped up to be as nearly as possible true planes, and were brought into excellent mechanical contact. Only when a very considerable force was applied to press them together did the resistance of the joint appear to vanish; except in this case it required a stronger magnetomotive force—a greater number of ampere turns in the magnetising coil—to bring the magnetic induction up to any assigned value when the bar was cut than it had required when uncut. In this respect the joint is equivalent to a narrow crevasse of air or other non-magnetic material. We proceeded to calculate the width of the air-gap, which should be equivalent, in magnetic resistance, to the joint, and obtained values which made it appear that the width of this equivalent air-gap became reduced when the magnetisation was forced up to high values. Having occasion recently to revise these results I found that an incorrect procedure had been followed in calculating, from the experimental data, the width of the equivalent air-gap. When the necessary correction is made it appears that this width remains constant, or nearly constant, whether the magnetisation be weak or strong. The object of this note is to point out the error in the former calculation, and to state the corrected values.

* From the *Philosophical Magazine*.

Suppose we have to deal with the magnetisation of a complete iron circuit, of uniform cross section, and of length l. Let the permeability of the iron be μ, for any induction B. The line-integral of magnetic force producing this induction is $\frac{Bl}{\mu}$, when there is no joint. Next suppose a joint to be introduced and to be equivalent in magnetic resistance to an air-gap of width x. The line-integral of magnetic force is then

$$\frac{Bl}{\mu}+Bx.$$

Distinguish by dashes the values of B and μ in this case from their values when there was no joint. Then, taking the same number of ampere-turns in the magnetising coil in both cases, we have

$$\frac{Bl}{\mu}=\frac{B'l}{\mu'}+B'x;$$

from which

$$x=\frac{l}{B'}\left(\frac{B}{\mu}-\frac{B'}{\mu'}\right).$$

In the Paper referred to we omitted to take account of the variation which the permeability of the iron undergoes when B is changed to B'. It is, however, essential to distinguish between μ' and μ if the plan is followed of finding x by comparing the inductions reached in the two cases under equal values of the magnetomotive force.

A better way, however, is to draw the curve of magnetisation in relation to magnetomotive force for each of the two cases, and then find, by measurement from the curves, what is the difference in magnetomotive force for one and the same value of the induction. This simplifies matters by securing that μ shall be the same when there is a joint as when there is none. If we write H for the magnetic force when there is no joint, and H' for the mean magnetic force required to produce the same induction B when there is a joint, we have

$$Hl=\frac{Bl}{\mu},$$

and

$$H'l=\frac{Bl}{\mu}+Bx;$$

from which

$$x=l\left(\frac{H'-H}{B}\right).$$

Thus, let a curve giving B and H be drawn, and another curve, with the same axes, giving B and H', then the distance between the curves measured parallel to the axis of H, when divided by the corresponding value of B, is proportional to the width of the equivalent gap. When this method is applied to the experimental results which were published in the Paper referred to it will be found that, for any given joint, the values of H' − H are nearly proportional to B. In other words, x remains nearly constant instead of becoming diminished as the magnetism is pushed towards saturation. One or two instances may be quoted.

In Table I. experimentally found values of the magnetic force due to the magnetising solenoid are given, along with the inductions observed when there was no joint and when there was a joint. The joint in this case was between carefully finished surfaces, approaching the condition of true planes. No externally applied mechanical force was used to force the surfaces together.

Table I.—*Influence of a Smooth Joint in an Iron Bar.*

Magnetising force due to solenoid.	Magnetic induction B.	
	Without joint.	With joint.
4	3,950	3,000
6	6,900	5,300
8	9,250	7,400
10	10,900	9,150
15	13,250	12,000
20	14,300	13,500
30	15,200	14,900

In Fig. 1 these results are shown by curves, and a third curve (the dotted line) is added to show the values of H' − H in terms of B. It will be seen that this curve is nearly a straight line; it should be straight if the magnetic resistance of the joint were strictly constant. Table II. gives values of the width of air-gap equivalent in magnetic resistance to the joint, as determined from this experiment.

Digitized by Google

Table II.

B.	Width of air-gap equivalent to the joint, in centimetres.
4,000	0·0026
6,000	0·0030
8,000	0·0031
10,000	0·0031
12,000	0·0035
14,000	0·0037

Data relating to a second experiment in which a cut with true-plane surfaces was introduced in another iron bar will be found in another Paper. Fig. 2 shows the graphic treatment of this example, and it will be seen that the dotted curve which exhibits $H' - H$ is in this case slightly concave towards the axis of B,

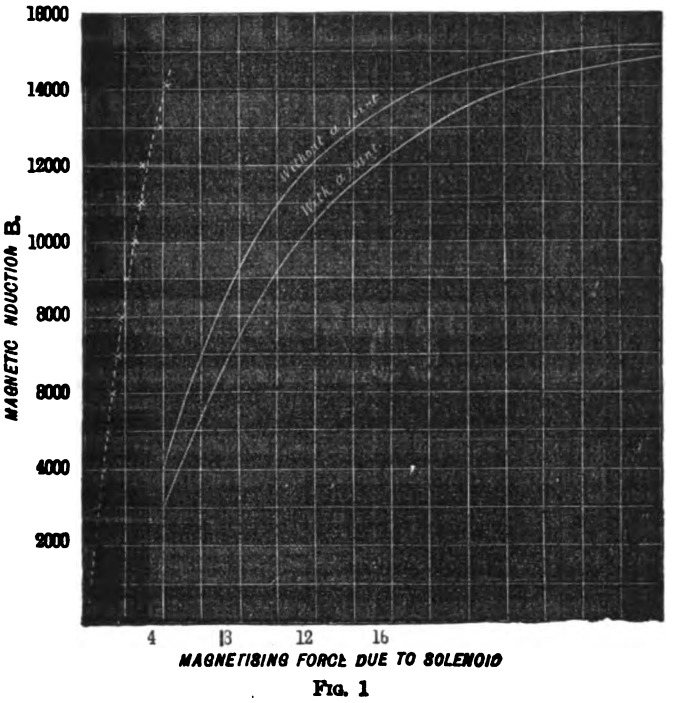

Fig. 1

whereas in the former example it was slightly convex. The deviations from straightness are in neither case more than may well be set down to uncertainty in the experimental data; and taking the two examples together it seems very probable that the joint is equivalent to an air-gap of sensibly constant magnetic resistance.

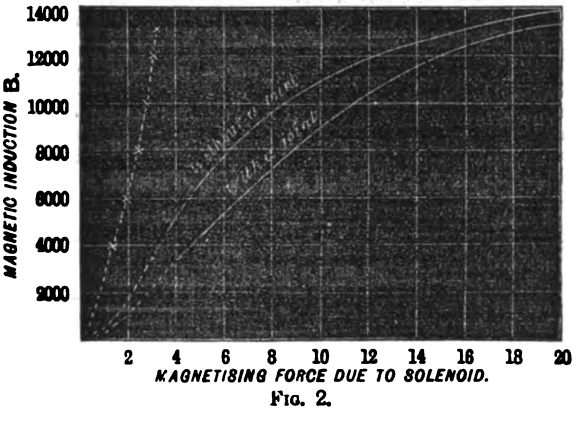

Fig. 2.

In the first example the width of the equivalent gap was about 0·0033cm.; in this case its mean value is about 0·0036cm.

Small as these gaps are, it is difficult to believe that the metallic surfaces were actually separated so far, and it seems more probable that the magnetic resistance of a joint is due in part to a reduction of permeability in the metal itself at and close to each surface, as a result of the influence of surface conditions in affecting the grouping of the molecular magnets.

Since the joint is equivalent to an air-gap of sensibly constant width it is easy to apply a graphic construction, like that used by Lord Rayleigh in the case of ellipsoids,* to determine the influence which the joint must exert in any cyclic or other magnetising process: or, conversely, to determine from experiments made on a circuit in which there is a joint the form which the magnetisation curve would assume if the joint were not there. The effect of a gap or of a joint is to make the true magnetic force less than the apparent magnetic force (namely, the force due to the magnetising solenoid), by an amount which is proportional to the magnetisation. We have $H = H' - \frac{Bx}{l}$. Thus a curve giving the relation of B to the magnetising force in a ring without a joint will serve to show the relation of B to the externally applied magnetic force on a ring with a joint if we re-draw it, merely shearing it over by inclining the axis along which B is represented through an angle the tangent of which (interpreted upon the proper scale of B and H) is equal to $\frac{x}{l}$. To take a practical instance, sup-

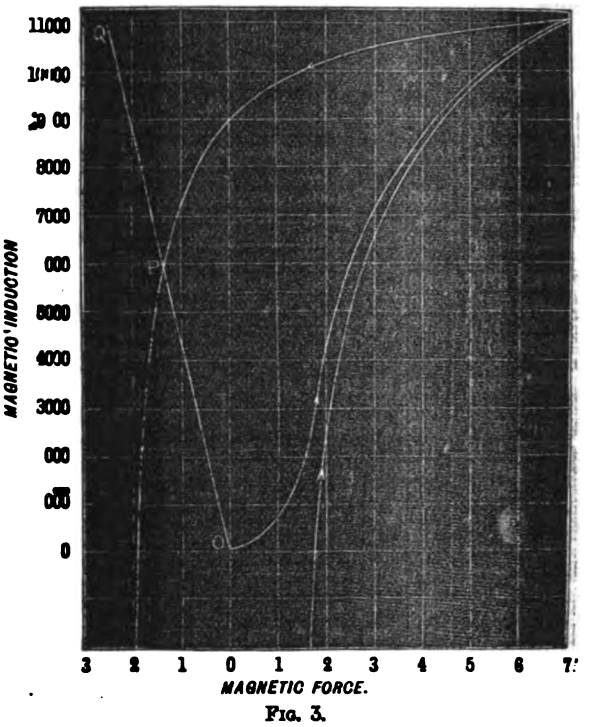

Fig. 3.

pose we have a ring of soft iron forming a magnetic circuit say 30 cm. long. Suppose the ring, when tested in the solid state, to give the curves B and H, shown in Fig. 3, which are actual curves for a soft wrought-iron ring. Let it be required to deduce from these curves the relation which the magnetism would have to the externally applied magnetising force if the ring, instead of being solid, were cut into two half rings, with carefully faced ends placed in the best possible contact. Each cut, as we have seen, is equivalent to a gap $\frac{1}{300}$ cm. wide. The two together make x equal to $\frac{1}{1500}$ of the length of the ring. Hence, if we draw a line O P Q in the figure inclined, so that H is—1 when B is 4,500, the intercepts between it and the axis of B represents the self-demagnetising forces due to the cuts at all stages of the magnetising process. Curves giving the applied force H′ in relation to B for the cut ring may then be drawn by using as abscissæ the distances of points on the original curves from the line O P Q, measured parallel to the axis of H. The reverse of this construction will, of course, serve to deduce true magnetisation curves (for uncut metal) from experiments made with a magnetic circuit which contains a joint or a gap.

The figure is drawn to scale for an actual case, and serves to show that the division of a ring 30cm. long into two half rings abutting against each other with the smoothest possible joints has the effect of reducing the residual magnetism from 9,000 to 6,000, which is the height of the point P. A similar shearing over of the curves, with consequent reduction of the residual magnetism occurs, to a greater or less extent, in magnetic tests of bars when these are made to form part of a complete magnetic circuit by the addition of a massive iron yoke.

* *Phil. Mag.*, August, 1886, p. 180.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided, after placing £14,000 to the reserve fund, and £6,610. 10s. to the debenture redemption fund, to recommend at the forthcoming meeting a dividend of 3s. per share, free of income tax, being at the rate of £2 per cent. per annum for the six months ended June 30th last, carrying forward £1,662.

UNDERGROUND MAINS IN PARIS.

The frequent references to the subject in the technical Press and the frequent accounts of explosions in the daily Press would seem to show that the Paris electric lighting companies are experiencing more trouble with their bare copper "canalisations" than is the case in London. Some few months since (*The Electrician*, Vol. XXVIII., p. 664) M. J. A. Montpellier propounded a theory and a remedy in the columns of *L'Electricien*, and below we reproduce, nearly in its entirety, an article by M. G. Claude which appeared in the last issue of *L'Industrie Electrique*.

The accidents, becoming every day more frequent, occurring in the vicinity of continuous-current mains make it clear that these "canalisations" possess defects which it was impossible to foresee, and which can only be got rid of by taking minute precautions. The phenomena are of different kinds, but the more common, presenting, moreover, the most features of interest, are somewhat as follows:—Gas pipes running near continuous-current mains become pitted all over and perforated in places. On the other hand, the stoneware conduit, or trough containing the conductors, is filled at these points with a mass of soda and potash salts, sometimes to the extent of several kilogrammes, although externally the conduit exhibits no sign whatever of being attacked. The conductors themselves, and especially the negative main, are so powerfully attacked that conductors having a cross sectional area of 40 sq. mm. (·06 sq. inch) have been ruptured. It is not a question of a particular instance, but of a phenomenon common to all the Paris electric lighting districts. Generally, the parts affected are the secondary mains, which are laid with less care, the conductors being run through stoneware without any insulators. It is also the branch lead gas pipes, which are often very close to the conductors, that are attacked. There are, however, several instances of tarred cast-iron and sheet-iron gas pipes being attacked. I have observed on a 50 cm. length of 20 cm. cast-iron gas-piping a dozen pittings 6 to 8 mm. deep, and from 1 to 3 mm. in diameter. Owing to the heat generated in the surrounding soil, and the proximity of the continuous-current mains, it was impossible to suppose other than an electrical origin to these pittings. The water pipes have not as yet been affected, simply because the mains and branches are not laid directly in the ground, but are placed in the sewers.

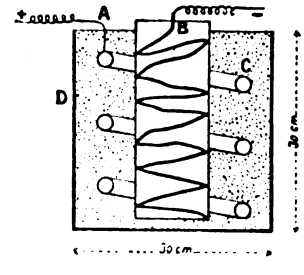
It has been sought to explain the street explosions by accumulations of electrolytic hydrogen in the conduits. But on examining the locality, it was found in the case of the Rue Notre-Dame-de-Lorette explosion that 52 gas branch pipes were perforated. The progress of the phenomenon is somewhat as follows:—Insulation at first satisfactory, progressively diminishes; small quantities of alkaline matter, due to slow electrolysis of the salts contained in the soil, soon reach the conductor; from this moment the insulation falls rapidly. The walls of the conduit, traversed by a stream of alkaline substances, acquire a continually-increasing conductivity. A large basic deposition takes place inside, the cable is corroded, and the leakage current may amount to 13 to 15 amperes, and the soil warms up for a considerable distance around. As the electrical and the gas mains are attacked simultaneously, it is easy to see how grave these accidents might become under certain circumstances, and how important it is that precautionary measures should be taken. Several of the companies concerned, and especially the Gas Company which is directly interested in the matter, have been moved by this state of things to undertake numerous investigations, with the view of elucidating the mechanism of these phenomena. The large amount of work which the Edison Company is carrying out at several points on its system are in some measure the result of these investigations. The following is the outcome of researches carried out by myself:—

An analysis of the alkaline deposits found in the conduits showed that their composition is sensibly constant. Several samples were made up as follows:—Soda, carbonate of soda, potash, carbonate of potash, lead, in large quantities; alumina, copper, lime, in appreciable amounts; traces of iron and silica. The presence of a considerable proportion of lead is interesting, and affords us a valuable index to the nature of the perforations. It proves, in fact, that they are not due to local fusion, an hypothesis in any case difficult to admit, but to electrolytic transportation. In some samples, however, lead was not to be found, and was replaced by iron, which was due to the fact that the current was directed on to tarred cast-iron or sheet-iron pipes.

This first point established, I endeavoured to reproduce the perforations. The arrangement which gave the best results was as follows:—A (*see* Figure) was a porous vessel, intended to represent the stoneware of the conduit, whilst having at the same time a lower resistance. B was a strip of German silver, bent so as to make as many contacts as possible with the sides of the vessel, and connected to the negative pole of a 120-volt circuit. C was a lead pipe wound round the porous vessel and connected to the positive pole. In order to localise as much as possible the attacks on the lead the pipe was covered with a coat of varnish very unequal and very thin at places. The whole was enclosed in a box, D, filled with a slightly moist mixture of sand and sea-salt. On applying 120 volts pressure all the phenomena observed on the mains were reproduced. The current, at first almost zero, gradually increased to more than 0·75 ampere. Tufts of alkaline matter soon formed at every point of contact of the German silver strip, and they grew in size during the entire experiment. At the same time the temperature rose to about 75°C. As to the pipe, at every spot where the layer of varnish, owing to its thinness, offered a low resistance, it was bleached by the action of chlorine, and the metal parts which it covered were riddled with pittings 1 to 2mm. deep and 2 to 3mm. in diameter.

These facts, which are in exact agreement with what was observed in the conduits themselves, seem to justify the following conclusion:—(1.) The perforations certainly do not arise from local fusion, since the current is always very weak. (2.) The size of the perforations is much too great for them to be due simply to transformation into chloride of the lead corresponding to the chlorine liberated by electrolysis. (3.) The proportion of chloride of lead found around the pipe is, on the contrary, very small; and again lead is found in the alkaline matter deposited on the negative electrode. At times, also, the formation of the tufts was accompanied by deflagrations, due either to the combustion of the sodium or to a too powerful local current. These deflagrations occurring in an atmosphere charged with gas may explain explosions which have taken place.

From these various observations we may conclude with some degree of certainty that things take place in the following manner:—The chlorine arising from the electrolysis finding itself in a nascent state in presence of lead forms first of all chloride of lead, but this compound being traversed by an electric current is electrolysed as fast as it is formed. The lead is carried to the negative pole, when it mixes with the soda and potash, whilst the regenerated chlorine attacks the subjacent layers of lead, which it penetrates more and more. Moreover, the resistance of the parts attacked becoming less



and less by reason of the stream of metallic matter, we can see that any fresh chlorine tends to go to these spots, and thus the depth of the holes tends to constantly increase, although the chlorine liberated may be very limited. In this way, also, is explained the transportation to the negative pole of the lead, to which the chlorine serves as a sort of vehicle; and also the almost complete absence, with the exception of a few white specks, of lead salts around the pipes attacked. This explantion is susceptible of a still simpler verification. If we subject a concentrated solution of chloride of sodium to electrolysis (which is what we do when we electrolyse soil only slightly damp), using as positive electrode a strip of lead, and as negative electrode a piece of carbon, the lead is attacked very rapidly, and a white precipitate of oxychloride of lead is formed and an appreciable proportion of the lead attacked is deposited on the negative pole.

In all that precedes I have supposed that the gas mains were in communication with the positive pole of the electricity supply. It may equally well happen that they are in communication with the negative pole, and in that case the effects produced should be different. Theoretically, the chlorides are still electrolysed as soon as the insulation of the "canalisation" falls below a certain value; the alkaline bases are carried to the lead pipe on which they can only have a feeble effect, whilst the chlorine is carried on to the conductor which it eats away, forming chloride of copper. In practice this class of phenomenon has not been observed. This is due probably to the fact that the passage of the chlorine through the stoneware does not lower the resistance as much as the passage of the soda and potash, and consequently this phenomenon cannot exhibit the constant growth which characterises the ordinary phenomena.

It may be concluded from the above that up to the present, with rare exceptions, the precautions taken to ensure the insulation of the continuous-current systems have proved insufficient, owing to the influence of a factor the importance of which could only be gauged by experience. The simple drawing in of cables through stoneware conduits should be absolutely prohibited, and even with insulated cables we should not be content to employ enamelled iron hooks, which become rusty, and offer a passage to soda and potash

Digitized by Google

salts. It follows, also, from these investigations that especial care should be taken with regard to the insulation of the positive main, since injury to neighbouring mains seems to have always been the result of communication with the positive. If, in laying down an electrical network, the two conductors will not be under equally favourable conditions, the positive should have the best position. Finally, a new solution of the problem is indicated by this investigation, which consists in adding to the good insulation of the positives a metallic connection between the negative and the neighbouring mains having a sufficient resistance to prevent accidental short circuits, say 50 to 100 ohms. We must make our choice. Either the insulation of the positive is sufficient, and will stand this earthing of the negative without inconvenience, or the precautions taken are insufficient, the insulation will go on decreasing, and after a long time electrolysis will again commence to take place. But now the neighbouring pipes being at the same potential as the negative will only receive alkaline deposits, the effect of which will only be slight, at first owing to the fact that their erosive action is much less than that of nascent chlorine, subsequently because the conditions of the case are antagonistic to the electrolytic transportation of lead. Reversals of polarity, and the accidents which arise from them, can then only take place when the insulation of the positive has fallen below that of the resistance connecting the negative to earth ; that is to say, when the faults are easy to localise and repair. In any case, the companies would only on this hypothesis have to do with defects of their own insulation, and other mains would be protected, which would be a great improvement. A still more radical cure would be to substitute alternate for continuous currents ; alternate current mains do not possess the same sources of deterioration, and, as we know, keep in a better state. But to realise this idea great progress will have to be made in the work of rendering alternate currents susceptible of applications as general and as convenient as is the case with continuous currents.

THE AGE-COATING IN INCANDESCENT LAMPS.*

BY EDWARD L. NICHOLS.

When an incandescent lamp is maintained at constant voltage it invariably falls off in candle-power. The diminution in brightness is attended by an increase in the amount of energy consumed per candle-power of light, this change being specially marked in the earlier portion of the life of the lamp. This phenomenon, which seems to take place in all incandescent lamps of the present day, was first studied exhaustively by Mr. W. H. Peirce, who read a Paper entitled "The Relation between the Initial and Average Efficiency of Incandescent Electric Lamps," before the American Institute of Electrical Engineers, in 1889.† Mr. Peirce made a careful study of 94 lamps, including nearly all the types of glow-lamp then in use. He found no exception to the rule of progressive degeneration.‡

These changes may be ascribed to at least three causes : loss of vacuum ; increase of resistance, due to the disintegration of the filament ; and finally, the deposition of the disintegrated carbon upon the inner surface of the lamp-bulb. It was the object of the experiments to be described in this Paper to make a study of this coating. We endeavoured (1) to determine its character—that is to say, whether it is colourless or is selective in the particular rays it absorbs ; (2) to learn something about the rate and distribution of deposit ; and (3) to determine how far the absorption of light by the coating is accountable for the diminution in the brilliancy of the lamp.

For the determinations under the first head we made use of a form of polarising spectro-photometer, which has been more than once described.§ The standards of light were incandescent lamps. These were maintained at a candle-power considerably below the normal, that the changes taking place in them might be slow. Frequent comparisons of their spectra showed that the relative changes of brightness and quality of light were inappreciable. The first step in our investigation consisted in the measurement of the absorption spectra of the bulbs of certain unused lamps, which had been selected for study. These lamps were then brought to degrees of incandescence, previously agreed upon, and were maintained in that condition by means of the current from a storage battery carefully kept constant, until they showed coatings of sufficient density to admit of ready measurement, They were then taken out of circuit, and the absorption spectra of the blackened bulbs were determined. These readings gave the amount of light of each wave-length absorbed, and, by repetition, the rate of deposition during different periods of the lamp's existence. The entire set of photometric observations were duplicated, but since the final results obtained by the two independent observers (Moore and Ling) were in agreement, only the mean of the two sets is given in the following tables.

In order to ascertain precisely what part in the decadence of the lamp is attributable to the coating, it was necessary to keep careful watch of the continually shifting electrical and photometric conditions during its entire life ; and in order to maintain in each lamp the precise conditions under which it had been determined that it should be burned, measurements of candle-power and voltage had to be made at short intervals, together with continual readjustments of the current. Fourteen lamps in all were selected for the investigation. These were of two widely different types, representing the two great classes, viz., lamps with untreated and with treated filaments. Of these, some were maintained at the voltage indicated by the maker, or at predetermined constant voltages other than this. Others were kept at constant candle-power throughout their entire life, the current being increased whenever the decrease in brightness due to increasing age had become appreciable. From the data obtained in this way, the life curves of the various lamps were plotted, showing the variation in candle-power or voltage respectively, of resistance and of efficiency expressed in watts per candle, during its entire existence. Some of these curves have already been published.* As these results were quite in accordance with those obtained by Mr. Pierce, to which reference has already been made, it will be necessary to deal with them here only in so far as they bear upon the question of the influence of the age-coating upon the efficiency of the lamp.

Colour of the Coating.

Measurements upon all fourteen of the lamps which were subjected to the spectro-photometric tests, showed the colour of the coatings upon lamp-bulbs containing treated and untreated carbons respectively, to be practically identical in character. The colour of the coatings obtained in lamps of either type, under widely diverse conditions (as, for example, by maintaining a 16 c.p. lamp at 64 candles throughout its life), was the same as that produced under normal conditions of service. The colour in question is very nearly neutral, the percentage of light transmitted being approximately the same for all parts of the visible spectrum. The effect of the "*age coating*," as the deposit which we are considering may be called, is therefore to dim the lamp, without appreciably changing the quality of its light.

The most complete set of observations obtained with lamps of untreated carbon are those referring to a lamp designated in our list as No. 2.† This lamp was maintained at normal voltage for over 800 hours. Frequent readings of candle-power and current during this time afforded the means of tracing the progressive changes of light-giving power, efficiency, and resistance. Measurements of the age-coating were made after 100, 200, 400, and 800 hours of life, readings being taken in ten regions of the spectrum. The results are given in Table I., together with data indicating the condition of the lamp at the above-mentioned periods of its life. These are taken from a set of 67 readings of voltage and current, distributed over the entire life of the lamp at nearly equal intervals. The variation in voltage during the entire 800 hours was never more than 0 3 volt above or below the initial value.

Another typical case was that of lamp of No. 10, which was a lamp with a treated filament. It was maintained at a very different degree of incandescence, being a lamp of low efficiency, which, when set at the voltage indicated by the manufacturer, required an expenditure of 5·16 watts per candle. The age-coating of this lamp approached even more nearly to complete neutrality of shade than did most of those which we had occasion to measure. The results obtained at 200 and 900 hours are given in Table II.

The normal life of a lamp starting at 5 watts per candle is many thousands of hours. Lamp No. 10 was prematurely broken at 908 hours, at which time the coating had reached a density corresponding to that of a 3-watt lamp (No. 2) after 200 hours of life. A comparison of Tables I. and II. will show that while the coatings on these two lamp bulbs were not quite neutral nor precisely identical in tint, that they both transmit light with much greater uniformity than do such materials, for example, as optical glass, calcite, &c.‡

The Distribution of the Age-coating within the Bulb.

The distribution of the age-coating was determined indirectly as follows:—Two of the lamps under examination were measured for horizontal candle-power, according to the "Franklin Institute" method;* measurements being made in 12 meridians, 30deg. apart. The readings were repeated at frequent intervals throughout the life of the lamps. The results were plotted with polar coordinates. They show (Fig. 1) by the diminishing area of the successive curves

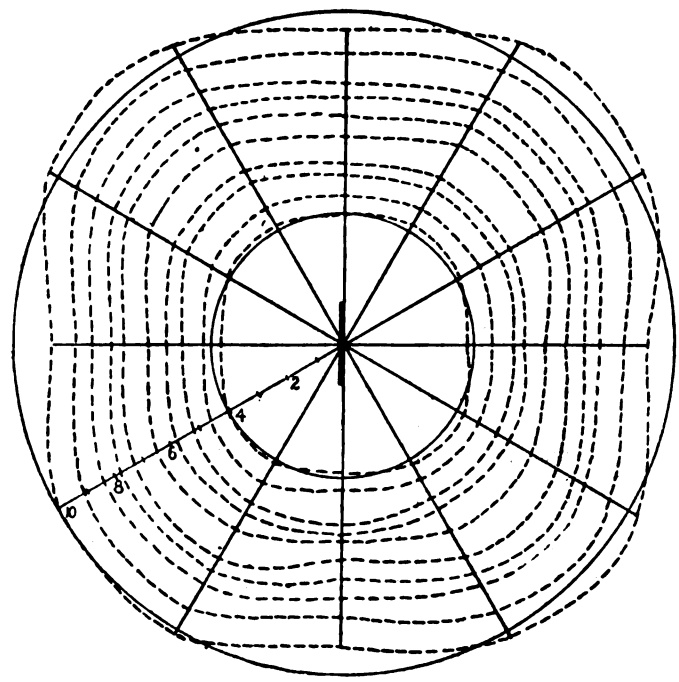

Fig. 1.

the progressive loss of brightness due to age, of which about one-half is ascribable to the coating. The similarity of the curves, from first to last, indicates that the coating is deposited uniformly within the bulb, or in uniform lateral zones, so that the density of the film is symmetrical with reference to any given meridian. The case chosen for illustration is lamp No. 7. The results obtained with lamp 8 were in every essential respect the same as those shown in the diagram.

The Age-Coating considered as a factor in the Diminishing Efficiency of the Lamp.

It may be seen from the Tables (I. and II.) that the absorbing power of the coating is in itself sufficient to account for a very considerable falling off in the candle-power, as the lamp, within the bulb of which it forms, grows old in service. By summation of the values in the tables, we may obtain the average absorbing power for the entire spectrum; and since selective absorption is almost entirely absent, these averages will give very closely indeed the loss in candle-power, which at the time in question was ascribable to the influence of the coating. From the data in Tables I. and II., also, we may compute the efficiencies of the lamps at various stages in terms of their initial efficiency as unity; likewise their brightness from time to time, in terms of their initial candle-power, as unity. In Tables III. and IV. are given, for purpose of

* *See* Franklin Institute Tests (International Electrical Exhibition, 1884), Philadelphia, 1885.

Digitized by Google

comparison, the relative brightness and efficiency of lamps 2 and 10, at various periods, also the average absorbing power of their coatings.

Table III.—*Relative Brightness, Efficiency, and Transparency of Lamp No. 2, at Various Periods (each expressed in terms of its initial value, taken as 100).*

Time.	Relative brightness.	Relative efficiency.	Relative transparency of bulb.
000· hours	100·	100·	100·
100 „	78·1	81·5	91·44
200 „	67·5	70·9	85·91
400 „	60·4	66·8	82·46
800 „	45·0	51·3	78·24

Table IV.—*Relative Brightness, Efficiency, and Transparency of Lamp 10, at Various Periods (each expressed in terms of its initial value, taken as 100).*

Time.	Relative brightness.	Relative efficiency.	Relative transparency of bulb.
0· hours	100·	100·	100·
50· „	92·6	92·6	—
109· „	91·4	90·1	—
200· „	86·6	87·3	90·5
400· „	80·5	81·6	—
511· „	78·7	80·0	—
600· „	78·0	79·5	—
900· „	—	—	85·0

The curves in Fig. 2 are based upon these data. They show that the loss in candle-power and efficiency are only in part due to the opacity of the coatings. It is of some interest to compare lamps

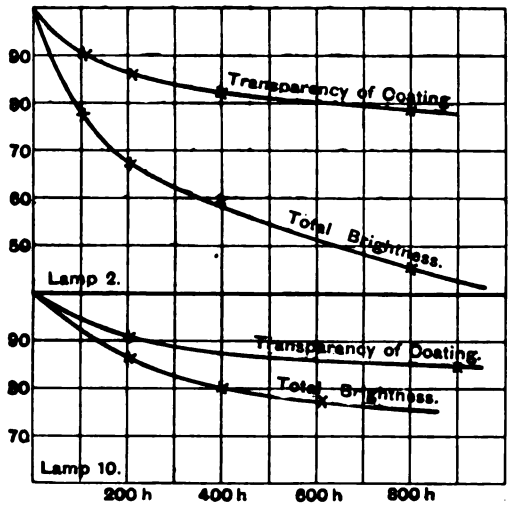

Fig. 2.

2 and 10, since the former is a 3-watt lamp, whereas the other required 5·16 watts per candle at the beginning of the test. It is to be regretted that the tests did not extend over the normal life-time of such a lamp; the results obtained, however, suffice to show that the loss due to coating is a much larger portion of the total loss in the low-efficiency lamp than in the other. Measurements with several lamps, maintained at abnormally high temperatures, seemed to indicate that the higher the state of incandescence the less marked (relatively) is the influence of the age-coating upon the decadence of the lamp.

Summary of Results.

1. The rate of deposit of the coating in incandescent lamp bulbs is greatest in the early part of the life of the lamp. For example, in the case of a lamp which lasted 800 hours (*see* Table III.) more than half of the coating was deposited during the first 200 hours.

2. The loss of brightness due to the absorbing power of the age-coating is a variable part of the total loss, being greatest in lamps of high initial efficiency.

3. The coating does not appreciably modify the character of the light which emanates from the lamp.

4. The distribution of the coating within the bulb is a nearly uniform one (*see* Fig. 1).

5. No marked difference between treated and untreated filaments appears to exist, as regards the density or quality of the coating produced from them.*

CORRESPONDENCE.

THE PRINTING OF MATHEMATICAL SYMBOLS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Having read the correspondence and Editorial Note on printing mathematical symbols in your last two numbers, I should like to offer the following suggestions:—

(1.) Fractions can always be printed like dx/dy by using parentheses; *e.g.*, your own example, $\frac{Im - L\omega}{Im + L\omega}$, would be printed $(Im - L\omega)/(Im + L\omega)$, without danger of ambiguity, and so on for even very complicated fractions.

(2.) Why not denote exponents thus: $|x|$; *e.g.*, $A\epsilon^{-ax}$ would be printed $A\epsilon|-ax|$, and so forth.

I am not aware of any usage of similar vertical lines which would cause confusion.—Yours, &c., R. Duncan.

Crowthorne, Berks, Oct. 15, 1892.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: May I point out that your criticism on my suggestion of the symbol $\epsilon\overline{\backslash -ax}$ to represent ϵ to the power $-ax$, that it breaks the "leading," does not apply to my alternative suggestion of the symbol $\epsilon\backslash(-ax)$. But it is, of course, for practical printers to decide on the question whether any plan, supposing it otherwise acceptable, saves them expense and trouble. The essence of the suggestion is to use the line \ to throw up the exponent, using at the same time a bracket of some kind to show what is the exponent if it be not a single letter. The exponent in its usual place is practically bracketed by being all above the line. If you bring it down, you must insert an actual bracket of some sort to show its extent. The underline would be the best under the circumstances, if practicable. I suppose that even if used with type for the index of a smaller size, thus, $\epsilon\underline{\backslash -ax}$ your objection on the score of extra expense would still apply?

There is not really any such difficulty as you suggest in representing a fraction like $\frac{Im - L\omega}{Im + L\omega}$ in a single line if brackets be used. It should be written $(Im - L\omega)/(Im + L\omega)$ just as the product of the same quantities must be represented by $(Im - L\omega)(Im + L\omega)$ and not by $Im - L\omega \,.\, Im + L\omega$. To insert these brackets is not really any alteration of the author's copy. In a fraction the numerator and denominator are each, in effect, bracketed by the line between them. If you bring up the denominator and abolish this line you must bracket the numerator and denominator respectively in some other way.—Yours, &c., Chas. T. Mitchell.

P.S.—As I am writing, I ought, perhaps, to say, that the line bracket over the exponent, $-ax$, should have been inserted in the fifth and not in the fourth line of my previous letter.

Toynbee Hall Electrical Society.—On Wednesday last the work of this Society was inaugurated at a social meeting held in Toynbee Hall. Amongst the speakers was Mr. W. H. Preece, who said he would do all in his power to further the scheme, which aimed at giving facilities for practical men in various branches of the electrical industry meeting together and exchanging ideas, both by means of reading Papers and experimental work. The Committee have some apparatus, but are appealing to the City Guilds and others for grants of money and further apparatus.

* Since this article was written it has been pointed out by Prof. B. F. Thomas (in the Paper already cited), that in the case of lamps exhausted without the aid of mercury, the age-coating is scarcely perceptible.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—Our readers are reminded that the tenders for the electric lighting of the Belfast Central Hotel are to be in by Tuesday next, the 25th inst.

——— The Glasgow Police Commissioners invite tenders for the supply of lanterns for electric lighting. Particulars of Mr. R. Hamilton, 52, College-street, and tenders to Mr. J. Lang, clerk to the Commissioners, by the 31st inst.

TENDERS ACCEPTED.—The Electrical Power Storage Company (Limited) have secured the contract for supplying the storage batteries for the St. James's and Pall Mall Electric Light Company's new station in Carnaby-street.

——— We understand that the Electric Lighting Committee of the Derby Corporation have accepted the following tenders for the building of the new electric lighting station, and for the engines, dynamos, &c. :—For the building, Messrs. Walkerdine and Co., £3,870. 4s. 3d. (engineers' estimate, £5,600); for the engines and dynamos, Messrs. Siemens Bros. and Co. (Limited), London, £10,781 (engineers' estimate, £10,500). The engineers are Sir Frederick Bramwell and Mr. Harris.

——— Messrs. W. T. Henley's Telegraph Works Company (Limited) have secured the contract for the supply of arc lights and cables for the Glasgow Corporation.

——— The contracts for lighting the Galatz and Kraila harbours at Bucharest have been placed with Messrs. Siemens and Halske.

SALE BY AUCTION.—Our advertisement columns contain particulars of the sale by auction, by Messrs. Bullock and Sadler, on Wednesday, November 2nd, of the stock-in-trade and plant of an electrical engineer at Brighton, comprising a 4-H.P. Robey steam-engine, a 2½-H.P. gas-engine, three dynamos, switchboard, 30 E.P.S. accumulators, a complete portable electric lighting plant, arc and incandescent lamps, batteries, &c., &c.

STEAM POWER.—Our advertisement columns contain particulars of extensive workshops with all necessary steam-power, &c., for electrical or experimental work, which are to let in the north-east district of London.

MESSRS. SHARP AND KENT.—We are informed that Mr. E. Jesse Piper has become a member of this firm, which will, however, be continued under the same name as previously.

MESSRS. VERITY AND SONS.—Owing to the growth of their electrical engineering business in the Birmingham district, this firm have taken offices at 116, New-street, Birmingham, above their large show-rooms. Orders for goods manufactured by the firm should be addressed to the Works, at Aston, Birmingham.

HOUSES OF PARLIAMENT.—Our contemporary, *Industries*, which was the first, some two years ago, to publish an elaborate and profusely illustrated technical description of the Forth Bridge, is now preparing a comprehensive description of the heating, lighting, ventilating, and sewage appointments of the Houses of Parliament, for a special number, which will be published on the 28th inst.

ELECTRIC TRACTION.—In the *Glasgow Herald* there is appearing from time to time a series of articles treating of new lines and new systems of electric traction. The last article appeared in the issue for October 14th.

DREDGER LIGHTING.—Messrs. Fleming and Ferguson, ship builders and engineers on the river Cart, Paisley, are completing the equipment of a powerful twin-screw steam hopper dredger for the Clyde Navigation Trustees. The vessel is to have a complete electric lighting outfit, which will include five 2,000 c.p. arc lamps for signal purposes and a number of glow lamps for the engine-rooms, &c. We hope they may succeed in this most troublesome task, as the vibration upon a steam dredger offers serious difficulties for both arc and glow lamps.

MILL LIGHTING.—It has been decided to considerably extend the electric light installation at Owen o'Cork Mill, Belfast, which already consists of 500 16 c.p. lamps.

ELECTRO-HARMONIC SOCIETY.—A smoking concert is announced for next Friday, the 28th inst., at the St. James's Hall Restaurant, W., at 8 o'clock.

TAXATION OF MACHINERY.—It is satisfactory to learn that in a case recently heard at the Durham Quarter Sessions the proprietors of the Ford Paper Works, whose assessment had been increased by £450, were successful on appeal, by which their assessment was reduced to the extent of £400, the Sunderland Union having to pay all costs. The result of the action should encourage users of machinery to resist unfair assessments whenever opportunity offers.

"THE IRONMONGERS' CHRONICLE."—A new monthly journal with this title has just made its appearance, and is intended to cater for the ironmongery, metal, iron, machinery, and allied trades. The annual subscription is 5s., and it is published at 139 and 140, Fleet-street, London, E.C.

MR. F. H. WHIPPLE.—The *Western Electrician* is responsible for the statement that Mr. F. H. Whipple, who is known in this country in connection with "Whipple's Reports" and "Whipple's Directory," has been arrested on a charge of obtaining money under false pretences.

DISSOLUTION OF PARTNERSHIP.—Messrs. Wynne and Barnard, electrical engineers, of 72, Grey-street, Newcastle-on-Tyne, have dissolved partnership; debts will be paid by Mr. W. R. Wynne.

BELFAST.—The *Belfast Evening Telegraph* of Friday last contains particulars of a report submitted to a Committee of the Belfast Corporation, which has had under consideration the question of the purchase of tramways and gas extension, and the introduction of the electric light. This Committee recommended that a Bill should be promoted in Parliament for the above purposes. With respect to the electric light, the Committee recommended that no undue haste should be taken to select any particular system, but (as stated in *The Electrician* of September 30th last) that the time had arrived when a 10,000-light installation capable of future extension should be undertaken, and they recommended that the services of an expert electrician should be obtained to advise as to the best method of procedure. The extension of the gas works was also recommended. The Committee's report has been adopted by the Corporation.

BLOCKLEY.—Some time back the village of Blockley was lit with the electric light, and at a meeting held lately it was decided to reinstal the light at an early date.

BRIDGEND.—The Local Board are taking steps to secure the introduction of the electric light on the lines of the installation at Lynmouth. Water is to be the chief motive power.——At a special meeting of the Board Mr. Morgan Williams was instructed to advise the Board with regard to the proposed lighting scheme, the Lighting Committee having recently visited Linton and other places for the purpose of obtaining data.

BRISTOL.—The Electric Lighting Committee of the Town Council have, subject to certain conditions as to the time when the work is to be finished, accepted the tender of Mr. C. A. Hayes for the erection of the central station building. The amount of the tender, which, it was stated, was not the lowest, is rather over £13,000. Mr. H. Faraday Proctor has been appointed resident electrical engineer to superintend the installation. The plans for the Central station were prepared by Mr. H. Williams, architect to the Committee, and the building is expected to be completed about July next.

DERRY.—At their meeting last week the Derry Corporation decided to put the provisions of their Electric Lighting Order into force, and for this purpose agreed to expend £12,500 for carrying the resolution into effect. The scheme they have under consideration is for the entire lighting of the City, and from the estimate prepared the Council calculate that a profit of £200 a year will result, in addition to a sufficient sum to provide a sinking fund to pay off the principal of the loan. The installation is to be proceeded forthwith on the lines of that adopted by the St. Pancras Vestry, London.

DUNDEE.—In connection with the installation of the electric light in this City, the Lighting Committee of the Police Commission have agreed to erect four additional 1,000 c.p. lamps in the High-street, at an initial cost of £100 and an estimated additional annual charge of £100.

GLASGOW.—Messrs. Mavor and Coulson are installing the electric light at the extensive premises of the National Telephone Company, including offices, the new exchange switch-room, stores, workshops, &c. This will render the National Telephone Company independent of the Corporation supply.

HACKNEY.—A special committee of the Hackney District Board of Works have issued their report, and in consequence the Board have decided to apply for a Provisional Order.

HAMMERSMITH.—The Electric Lighting Committee have scheduled the thoroughfares through which the Vestry are to lay distributing mains within a period of two years from the commencement of the Provisional Order. The following is the list of thoroughfares:—King-street, from Broadway to Ravenscourt-park; Broadway; Hammersmith-road, from Broadway to St. Paul's School; Queen-street, from Broadway to further side of St. Paul's Church; Brook Green-road; Shepherd's Bush-road; across Shepherd's Bush Green to corner of Wood-lane; Goldhawk-road to Starch Green Pond; and Uxbridge-road to the corner of Percy-road.

HAWICK.—In reference to the Note appearing in our last issue, we are requested by Messrs. Mavor and Coulson to state that the sum of £820 is the annual cost of lighting of street lamps, and not, as the Note seemed to indicate, the prime cost of the scheme.

Digitized by Google

NEPAL, INDIA.—An installation of the electric light of considerable extent has just been completed in the palace of His Highness the Maharajah Beer Schumshere, Prime Minister of Nepal. The installation consists of 250 16 c.p. incandescence and 10 300 c.p. incandescence lamps, and a 40,000 c.p. search light, the latter of which is capable of throwing out sufficient light to illuminate the whole of the valley in which the palace is situated. The Calcutta, India Rubber, Gutta Percha and Telegraph Works Company have installed the light under the supervision of Mr. Lester Betts.

NOTTINGHAM.—The Electric Lighting Committee of the Nottingham Corporation have been busily engaged considering the old question of the public lighting of the borough. It is expected that their report will be presented to the Town Council shortly.

QUEENSFERRY.—At their last meeting the Town Council had under consideration the question of installing the electric light in lieu of gas, by which the town is now lighted, and after discussion the matter was remitted to a Committee, with power to employ an expert to report upon the cost. The Town Council have considerable water power at their command.

RICHMOND (SURREY).—The Electric Lighting Committee of the Local Board have reported on the negotiations between their representative and those of Messrs. Latimer Clark, Muirhead, and Co., and the plans for the proposed new buildings have now been approved. The work will be proceeded with immediately.

ST. PANCRAS.—In reference to the supply of Brockie-Pell arc lamps for the extension of the lighting of St. Pancras, for which we have previously intimated that the tender of Messrs. Johnson and Phillips had been accepted, the amount of the tender was £1,496. 11s. 8d.

SHOREDITCH (LONDON, N.E.).—Dr. H. Mansfield Robinson, solicitor and vestry clerk, has recently presented to this Vestry an exhaustive report in reference to the electric lighting of the district.

COMPANIES' MEETINGS & REPORTS.

The Brazilian Submarine Telegraph Company (Limited).

The 38th ordinary general meeting of the shareholders of the Brazilian Submarine Telegraph Company (Limited) was held at Winchester House, Old Broad-street, London, on Wednesday, Sir James Anderson in the chair.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting, and the minutes of the last meeting which were signed as correct.

The report was taken as read.

The CHAIRMAN: I will, as usual, make such remarks as appear to me appropriate, and I need only refer to some of the leading points in the accounts to begin with, and then go on to say, with prudence, I hope, what is in my mind with reference to the competition in which we are engaged, and upon which so much of our future prospects depends. The leading points in our report and accounts are as follows:—There is a decrease in revenue of £15,216 as compared with the preceding half-year, mainly due to the low rate of exchange. This, I am glad to say, is improving. We have spared no effort to raise our charge of currency to meet this loss upon our sterling receipts, and we are continuing to work to this end, apparently, I am glad to say, with some hopeful result. There is a decrease, however, of £47,035 in our revenue as compared with the corresponding half year of 1891, but the revenue of that half-year was abnormally large, due to the disturbed state of affairs in several of the South American Republics, which we had no right to expect would be continuous, and we had no right to hope that it would be so. The total expenditure is £2,929 less than in the previous half-year. The repairs of cables cost less by £9,633, but we were compelled to increase our staff for the working of our duplex system, and necessarily we had to increase the accommodation for that staff, as there are no houses at St. Vincent. We had also to erect tanks for our spare cable, and to extend our office accommodation at a cost for this half-year of £1,150. Then there was the cost of applying duplex to No. 2 cable, £3,000 of this cost falling due in the half-year under review, but this cost will now be reduced to £500 for each half-year for the next six years. I may inform you that the duplex has been of immense value to our working. Working both ways is a great benefit, and we can, when we think proper, work both ways on the next cable also. This brings the total decrease of expenditure to £2,929. With your permission I shall not refer to all the items of increases and decreases in the balance-sheet unless you desire it. Of course I have them all before me. Let me now refer to such criticisms as have come to hand from three of our proprietors. Out of 2,900 shareholders we have had three letters. Naturally, we receive such criticisms with all respect, and we consider among ourselves whether our policy can be defended upon business principles in the best interests of the proprietors, the efficient maintenance of the property, and the security, so far as it is possible, of our revenue for the purposes of dividends. For several years I have warned you that something like a crisis was coming, and now, at this moment, we are face to face with a rivalry which will test the wisdom of the policy of this Board since the formation of the Company 19 years ago. One honourable proprietor is of opinion that we ought not to make extensions out of revenue, but add all to capital, and that all such expenditure as can be properly debited to capital account should be so treated. Of course, as a matter of book-keeping there is much to be said in support of such a contention, but if such a policy were adopted in practice, then farewell to quarterly dividends; and when, in the course of time, a large expenditure of capital became imperative, it could only be got upon such onerous terms as would postpone or destroy all prospect of any dividends upon our ordinary stock, whereas, with a large reserve, such as we now have, and with a moderate amount of debentures, we could at once lay another cable if we desired to do so. We are in this position: our revenue-earning capacity is secure, even though a tariff war should be forced upon us. We shall not willingly initiate it, but we are directly threatened with it, both on the West and on the East Coasts. A reduced tariff, however, would no doubt increase the traffic, and besides being in a position to carry it better than any other Company, if the fight were too hard, we have the interest of our reserve to fall back upon for dividend purposes, if need be, as supplementary to our income from traffic. I hope you are observing that point. We are not exactly on our backs if we have a great opposition, for we have this reserve of interest to fall back on, and we should not have to go without a dividend, even though we dipped into the reserve. We are not so weak, therefore, as our opponents think—at least I believe so. Your Directors have always followed the principle of keeping the capital down, satisfied if they can pay a fair dividend, and keep a strong reserve. The other honourable proprietors who have written to us are of opinion that we ought to pay a larger bonus, and they tell us what we are very conscious of—that the sum carried to reserve is large in proportion to the dividend. That is very true, but we have a property liable to attack, and which is being attacked at the present moment, and in a manner which seems to leave no alternative short of a war of tariffs. It looks like that at the present moment, but a great deal may happen between just now and by-and-by. We are warned by our rival on the West Coast that if we do something—which we certainly shall do and must do—he will reduce the rates, but we are not without resources to meet that threat if it is to be put into practice. He has, so far, lowered the tariff, and so have we. On a previous occasion I told you we had reduced our tariffs by 33 per cent. and 50 per cent., and we can go as low as any Company can, and not be altogether without a dividend. I think I told you at our last meeting who our rival is. He has a cable from Galveston to Valparaiso. A few years ago this Company worked in harmony with a Company called the West Coast of America Company, going from Lima and Callao to Iquique, Arica, and the ports down to Valparaiso. For some reason not known to me yet this gentleman disregarded his partners and carried his cable down to Valparaiso, leaving the West Coast Company's cable out in the cold. It so happened that the Globe Company was largely interested in this cable, and they did not see, and do not yet see, why that cable should be ruined, and they do not intend that it shall be. In order to protect that cable a Company has been formed to lay a land line across the Andes from Buenos Ayres to Valparaiso to connect the West Coast of America cable with the East Coast cables, so we shall have in a few months' time cable communication all the way from London to Lima, from Peru to England and Europe, and our friend threatens us, as I understand, that if we do not let it alone he will do something very dreadful and come and attack us on the East Coast, as he has done for years. We are making this line, however, across the Andes. It is three parts made already, and do what he will we shall fight for it, and we shall then see what happens. Then there is the Company on the East Coast—from Senegambia to Pernambuco. That cable has been making for the last two years, and is now opened or about to be opened for traffic. The promoters sought to raise money by the avowed and published statement that they would take £80,000 per annum from this Company or the joint-purse Companies; and they opened their cable at a tariff 4d. per word lower than the tariff agreed upon—as fixed and tabulated by the Paris Conference as the obligatory tariff by every route for extra-European traffic. I will explain that. The Telegraph Convention, which meets every five years, have agreed that all traffics transitting any part of Europe is a certain traffic, and that no Company should come in and have a lower tariff, the object of the Convention being to create as many routes as possible for telegraphic communication at equal rates—not opposition rates. That is called the European *régime*. For extra-European traffic there is a higher tariff charged over the land lines transitting Europe, because they say—and properly say—if we have to maintain land lines all through Europe, Russia, Italy, and those great distances, and have to maintain them for extra-European traffic, necessarily, as there is nothing else going over those lines, we must have a larger tariff. There is, therefore, a European *régime* and an extra-European *régime*, and the Convention say that these two tariffs should be common to all comers, but no one is to come in and oppose us and the European Powers by some accidental line got up for promoting purposes. Therefore we are leagued together at this Conference to establish a tariff to all comers. It seemed strange to us that a private company, in disregard of inflicting loss upon every European state and upon the cable companies more especially, should, without any attempt to negotiate, rush before the public with a reduced tariff for no reason in the world but to force us to make terms that would give a value to their property which it does not now possess, as it is, so to say, a fifth wheel to a coach. Now, gentlemen, I did not wish to say so much even about that cable, but it is due to you that I should say something about a rival that has just come into the field. Its promoters, who are also its proprietors, are not allowed to carry their traffic lower than the Convention rates; but they are, I am told, carrying Press traffic free—or they were doing so two days ago. They are, as they say, determined to worry us into terms which they hope will enhance the value of their speculative cable. All I say just now is that we shall see. They pretend friendliness—and personally we are all friends; but they leave no

Digitized by Google

stone unturned to injure us, and it is possible they may tire of carrying even Press messages for nothing. At all events, it does not frighten us. Then there is the Antilles cable, which is owned by a French company, and which goes from Cuba down to Vizeu (Para). They hope to get a Concession from Portugal to go to the Azores. That was given to us, but by some superior diplomatic action it was taken from us. As I have said, this French Company are now trying to get in, and if they can obtain from France a subsidy of £80,000 per annum, they propose to carry that cable and join it on to the Antilles cable. I do not know that France is very much inclined to pay this £80,000, and at all events they have not got it yet. You will observe, from what I have now said, that it is a very costly fight that is now going on, but I venture to believe that you will approve our policy of paying a moderate dividend, and making a strong reserve equal to a system of offence or defence. We are carrying messages from Buenos Ayres to England within the hour (applause), and from Pernambuco and Rio Janeiro within the half hour. Commerce cannot want greater facilities than that, unless it be that we shall carry telegrams free, and that we cannot do. We are just now in a position as if a merchant in London had his foreign correspondent in the same building, and they carried on their inter-communication by what someone has called a whispering gallery. There is no system of international telegraphy which can beat us. I do not know what science has yet in store for us, but so far we do not know that there is anything looming in the distance that can excel what we are now doing, and we can adopt anything that may be proved to be better or faster. Our cables are duplicated and duplexed, our speed of transmission cannot be excelled, and we have a substantial reserve, which enables us to look our rivals in the face, and we certainly need not be under any feeling of panic or alarm. That is the position we are in, and in my opinion it is a very sound one. We have laboured at it all along for 19 years, steadily pursuing the policy of building up a reserve fund, and warning you from time to time—I have told you frequently—that this was our backbone, and that while we were paying a good dividend you must be satisfied to let the Directors take from revenue what you can spare to strengthen our position. I look forward to this, that with our reserve fund, that if we were in a tight fight we could do two things: we could take the interest on the reserve fund and put it to the reserve, and not add any more to that fund; or we could take it for increasing your dividend, plus any dividend arising from revenue from the traffic. I, therefore, do not address you in a pessimistic spirit or in a despairing tone, for I think we are in a good sound position. If any shareholder desires to ask any question I will do my best to answer him. Meantime I propose the following resolution:—

"That the report of the Directors and the accounts to June 30, 1892, now submitted be approved and adopted, and that a dividend be now declared of 3s. per share (making, with the interim dividends already paid, a total dividend of 6 per cent. for the year ended June 30, 1892) and also a bonus of 1s. per share in respect of the profits for the year ended June 30, 1892, the said dividend and bonus to be respectively free of income-tax."

I may add, in a word, that that is for the period ended June 30th. From that time to now we are still doing very well.

Mr. FREDERICK YOULE seconded the motion.

Dr. H. ELLERY TREWHELLA said he thought that the policy of a large reserve fund was an exceedingly wise one, and he was glad to find that the Directors still intended to continue that policy. He thought it possible, however—without wishing to call into question the Directors' policy—that, instead of increasing the reserve fund by £80,000 or £90,000 a year, they might see their way to putting to it £10,000 or £20,000 a year less.

The CHAIRMAN said he quite agreed with what Dr. Trewhella had said, but he would not like to pledge the Directors to anything at the present moment.

The resolution was then carried unanimously.

On the motion of the CHAIRMAN, seconded by Lord SACKVILLE A. CECIL, Sir Henry D. Gooch, Bart., was re-elected to his seat at the Board, as was also the Duke de Loulé, on the motion of the CHAIRMAN, seconded by Mr. J. DENISON PENDER.

The Rev. N. WILLIS then proposed the re-election of the auditors, Mr. Henry Dever and Mr. John Gane.

Mr. W. C. WEST seconded the motion, which was adopted.

Mr. W. GRIFFITH congratulated the shareholders on having such able statesmenlike men at the head of the Company's affairs, and said he was sure that their policy commended itself to the proprietors at large. The fact that their system was duplicated might render unnecessary the building up of their reserve fund much larger, but the shareholders must remember just now that the clouds were gathering somewhat. It was therefore well to be prepared, more especially as whatever was put to the reserve fund would make their dividend more secure. He concluded by moving a vote of thanks to the Chairman and Directors.

Dr. TREWHELLA seconded the motion, which was unanimously carried.

The CHAIRMAN having acknowledged the vote, said: Lord Sackville Cecil reminds me that there is one point which I have not mentioned, namely, that one of our cables is 20 years old. We are, however, repairing cables older than that, and I am not frightened; but still, everything points to the necessity of a strong reserve. Do not ask us, therefore, to "back down" on that any more than we are willing, but we understand the desirability as much as you can of doing so whenever we are able to.

On the motion of Dr. TREWHELLA, seconded by Mr. J. T. PRATT, a resolution was passed recognising the zealous services of the staff at home and abroad.

The CHAIRMAN said that it would give him much pleasure to let the staff know of the appreciation in which their services were held by the shareholders.

The proceedings then terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

BIRMINGHAM IRON AND STEEL STAMPING COMPANY (LIMITED).—A Company has been registered under this title with a capital of £3,000 in £1 shares, to acquire, take over as a going concern, and carry on the business of iron and steel stampers, electric light fitting manufacturers, iron founders, mechanical and electrical engineers, carried on under the style of "The Birmingham Iron and Steel Stamping Company," at Aston-lane, Aston, Birmingham, and to enter into an agreement with Mr. O. Ward, of Acock's Green, Worcestershire.

ELIESON ACCUMULATOR BRITISH PATENT SYNDICATE (LIMITED).—This Company was registered on October 13th, with a capital of £12,000 in £1 shares. The objects are: To acquire from Mr. Chaimsonovitz P. Elieson the exclusive rights for Great Britain and Ireland in his patent for electric accumulators, No. 7,697 of May, 1891, with a view to enter into and carry into effect an agreement, particulars of which are not given, and to carry on the business of manufacturers of, and dealers in, electric storage batteries, electric locomotive engines, electric tram engines, dynamo-electric machines, torpedo boats, dynamos, and every description of apparatus required for or capable of being used in connection with the generation, distribution, supply, accumulation and utilisation of electricity. The subscribers are:

	Shares.

Watson Smith, 6, Great Winchester-street, E.C.	1
Frederick C. Smith, 6, Great Winchester-street, E.C.	1
Edward Spendlove, 33, Southfield-road, Wandsworth, S.W.	1
Stanley W. Smith, 6, Great Winchester-street, E.C.	1
Graham S. Ridley, 6, Great Winchester-street, E.C.	1
H. Arthur Davies, 3, Platt's-lane, Hampstead, N.W.	1

The number of Directors is not to be less than three nor more than seven, the first being the above signatories. Qualification (other than that of a subscriber), £500.

NEW ZEALAND ELECTRICAL SYNDICATE (LIMITED).—An agreement dated September 22nd, between this Company of the one part and the Gülcher (New) Electric Light and Power Company (Limited) of the other part, states that on December 24, 1890, the New Zealand Syndicate and the Gülcher Company agreed that as soon as the Syndicate was clothed with the necessary statutory powers for supplying electricity or electrical energy for private installations and use in the City of Wellington, New Zealand, the Gülcher Company would sell to the Syndicate all its rights in and under a certain contract, dated August 3, 1888, together with the lands, buildings, stores, machinery, and plant of the Gülcher Company in Wellington for £20,000, to be fully satisfied by the allotment of 2,000 fully paid up £10 shares in the Syndicate, and that these necessary powers having been obtained it was agreed that the Syndicate should issue the 2,000 shares, numbered 1,001 to 3,000 inclusive. The Company was registered on December 20, 1890, with a capital of £30,000, in £10 shares, to supply electricity in New Zealand, Victoria, New South Wales, North, South, or Western Australia, Tasmania, New Guinea, the Fiji Islands, and elsewhere in Australasia. The last return shows that 955 shares have been taken up, and £1,000 paid in respect of such shares.

NORTHERN COUNTIES ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—The name of this Company is to be struck off the register unless information respecting its position is shortly forthcoming. The last return was filed November 17, 1890.

VEALE AND CO. (LIMITED).—The statutory return of this Company, made up to October 5th, has been filed. The Company was registered on May 26th last with a capital of £10,000, in £1 shares. At the time of making up 4,904 shares had been taken up, of which 3,644 had been considered as fully paid. Upon the remaining 1,260 shares the full amounts had been called, resulting in the payment of £1,235, and leaving £25 in arrears.

CITY NOTES, &c.

BERLINER ELEKTRICITATSWERKE.—A dividend of 7¾ per cent. has been declared on the past year's working.

CALLENDER'S BITUMEN, TELEGRAPH AND WATERPROOF COMPANY (LIMITED).—The directors of this Company have declared an interim dividend at the rate of 8 per cent. per annum on the capital of the Company, payable on November 1st next.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended October 16th were £902, as against £794 for the corresponding period of last year, being an increase of £108. The total receipts for half-year amount to £12,518, against £11,415 in the corresponding period of 1891, being an increase of £1,103.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment by warrants on November 1st next of interest for the half-year ending October 31st, on their Four per Cent. Mortgage Debenture Stock. The transfer books will be closed from October 27th to November 1st, both days inclusive.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—There has been a recovery in the price of the shares of this Corporation during the past two or three days, as will be seen from the share list. The rise represents an advance of 1 over last week's prices.

NEW AUSTRALIAN ELECTRIC COMPANY (LIMITED).—At the half-yearly meeting held at Melbourne on August 29th, the Chairman, Prof. Kernot, said that the electric light was making great headway in Mel-

Digitized by Google

bourne—in fact, the demand for the light was more than they could supply with their present capital, which he hoped they would be able to increase.

PETROLEUM ENGINE COMPANY (LIMITED).—The Directors recommend the declaration of a dividend on the 18,754 shares in the Company at the rate of 1s. per share, free of income tax, for the year ended June 30th last, leaving a balance of £236 to be carried forward. The shareholders meeting, held at Winchester House on Wednesday, was private.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—A private meeting of the holders of founders' shares in this Company was held on Tuesday last at Winchester House, E.C.——The electric current sold by this Company for the quarter ended September 30th amounted to £5,763, as against £5,279 for the corresponding period of last year.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the fortnight ended Oct. 15, 1892, were £2,470, compared with £1,492 for 1891, showing an increase of £978.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Oct. 14, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,611.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 754.—Vol. XXIX. FRIDAY, OCTOBER 28, 1892. PRICE SIXPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

One of the most useful functions of the London Chamber of Commerce is to encourage, by various facilities, the concerted action of the members of its numerous sections, and to ascertain the intentions of those who are supposed to be interested in any particular matter. In the case of the introduction of the B.A. standard screw-thread, those who did not use it were surprised to find the extent to which it was employed at the time of the issuing of the circular (July, 1889); many who were then hesitating decided to adopt it, and though the Chamber of Commerce cannot be said to have introduced the idea, or to have thrust this screw gauge upon its members, the result of its efforts was practically the same. But to thus encourage a common movement it is essential that someone should make a start, and in the case of the Chicago Exhibition, a circular asking the members of the Electrical Trades' Section whether they intended to send exhibits received not a single reply. This result fully confirms the view which we have always taken of this matter. No doubt the General Electric Company and the Electric Construction Corporation will be worthily represented, and will show what other English manufacturers could have done had they cared to add to the attractions of the show.

In 1889 M. Victor Popp was the lucky recipient of an electric lighting concession covering a large portion of Paris, and inaugurated his now well-known system of dotting dynamos about in storage battery sub-stations, and obtaining the necessary motive power from his compressed air mains. Such a roundabout way of generating current for the lamps has kept the concern in a perennial state of financial difficulty. A short time since the compressed air and electric lighting enterprises were amalgamated, the German house which had financed them having got into difficulties and its liabilities having been taken over by the Disconto Gesellschaft of Berlin. As a result of this amalgamation and change of proprietors, a clean sweep has been made of the original management; and this step, calculated in any case to arouse French susceptibilities, having been taken with characteristic Teutonic *brusquerie*, seems likely to result in a revocation of the concession, a perfectly legal proceeding, since by its terms none but Frenchmen are allowed to work it. In case of siege the provisions for the Paris garrison would be stored in cold-air chambers, and the possible consequences of allowing a German concern to run this important system of cold storage cannot be contemplated by the authorities without a shiver.

The interesting article by Lieut. Bacon on Search-lights, which we print this week, reveals the fact that the use of projectors in naval warfare is very different to the demonstrations which are familiar to sightseers at exhibitions. The name "search-light" is indeed rather misleading, for groping about like a policeman with a bull's-eye lantern is by no means an efficient method of using these much-discussed weapons.

Our readers will be glad to notice that the progress made in connecting life-saving stations along the coast has already done something to justify the expectations of its promoters, and to warrant the establishment of a complete chain of electrical communication. Three different cases were reported, during the recent storms, of lifeboats having been summoned, or their assistance being expedited, by the use of the telephone, and resulting in the saving of several lives.

With a total mileage of wire amounting to over 739,000, and offices numbering nearly 21,000, the Western Union Telegraph Company may justly claim to be one of the biggest of America's big concerns. It may also be considered, financially speaking, one of the most successful. For although dividends have not increased they have been steadily maintained during the past four years, and the surplus has been augmented by about five million dollars. The figures which are furnished by our American correspondent this week seem to indicate, however, that this gigantic business has reached a point at which further development brings no proportionate increase of profit, the working expenses growing rather more rapidly than the receipts. Nevertheless, new offices continue to be opened at the rate of some 600 annually, a fact which speaks wonders for the prosperity of the country, and hardly less so for the enterprise of the Company.

Of two evils, namely, premature publication of the results of a research, followed by hasty criticism, and on the other hand, reticence which ends in publishing a big Paper before a big Society, or nothing, the former is, perhaps, the lesser. When, at last, an important investigation has been concluded, and perhaps years after the commencement of the work the Paper is in the hands of the scientific public, interest in what was subject of importance may have faded. By giving a preliminary notice appetite is whetted for more, undue criticism is disarmed, and a title to priority, the coveted reward of many an investigator, is firmly established. If contributions to science fell, as the gentle rain from Heaven, through-

Digitized by Google

out the year, instead of in a deluge during the St. Swithin period of Societies' meetings on which we are now entering, mental digestion, to return to our former metaphor, would be more easy.

THE recent publication of some of the results of Profs. FLEMING and DEWAR'S investigations on the resistance of metals and alloys at low temperatures was an excellent example of the course which we advocate, and it has called forth some very interesting remarks by M. GUILLAUME of the French Standards Department. Some of his comments, which will be found in another column, may be answered by the further publication which is expected, and the others are in themselves of great interest. We ventured to append to our notice of these experiments diagrams plotted from the results. Since M. GUILLAUME has called attention to the apparent error at – 80°C., we may point out that this was very clearly shown in our diagrams on page 612 and 614 of *The Electrician* for the 7th inst. We hesitated, however, to allude to it at the time, since the investigations were confessedly incomplete; and on a former occasion, when we discovered a somewhat similar discrepancy, after plotting the results given in an abstract of a Royal Society Paper, by other authors, our desire for accuracy was not received with that philosophic calm which should adorn the scientific mind.

ON a recent occasion we referred to the use of electric locomotives in mines, and expressed surprise that they were not more frequently used, now that the trolley had become so general for tramway work. The General Electric Company of America are apparently fully alive to this class of mining work, and have already standardised electro-locomotives with draw-bar pulls varying from 750 to 4,500 pounds. The machines are designed to travel at from six to ten miles per hour. The overall dimensions for a 30in. gauge locomotive, with a 3,000 pound draw-bar pull, are 9ft. 6in. long, 4ft. wide, and 3ft. high; the wheel base is 3ft. 4in., and the total weight 15,000 pounds. These figures are very satisfactory, and promise a strong, compact and handy machine. The weight is, perhaps, the only difficulty, but it must be recollected that as soon as a dead load of one ton or so is exceeded it is necessary to use heavier rails, and to keep the track in better order than is usually the case for light haulage where the unit trucks average, perhaps, 15cwt. each.

THE design of the framing of this locomotive successfully meets many of the objections raised against the use of electricity for haulage underground. The frame consists of a single massive casting, box-shaped, with recesses for the axle-boxes. The motor is placed in the centre, between the two rolling axles, to each of which it is coupled by double-reduction tooth gearing. A space at one end forms the operating platform, and another at the other end makes a convenient place for the rheostat used in starting. The brake levers and the trolley are also attached to suitable parts of the framing. The body of the motor consists of two main castings, the lower forming the bottom pole-piece and carrying the bearings for the armature and the two intermediate shafts. The top pole piece is part of the upper field casting, which completely covers up the armature, field coil, and the other interior parts. The single exciting coil is wound around the top pole-piece. From a mechanical point of view the design is excellent, with the exception of the use of iron castings, which is always objectionable when a machine is subject to rough usage; but probably steel will shortly be employed instead.

IF chemists had known a little more of the fundamental principles of electricity, or electricians had concerned themselves with one of the prettiest applications of the special form of energy with which they are primarily concerned, an investigation now announced as depending upon a "new principle" would have had no ground for claiming to include any point of novelty, and the resources of the analyst would have long been enriched by a method of considerable utility. All chemists realising that there is a direct relation (obscured it may be in many cases, but clear enough in some, and indubitably existing in all) between the heat of combination of the constituents of an electrolyte, and the electromotive force needed for its electrolysis, have been aware that there is a fair prospect of founding methods of analytical separation on this fact.

ELECTROLYTIC analysis is, unfortunately, a cult confined to the comparatively few, largely because the necessary electrical supply is not in everyone's hand, and its immediate disciples have been somewhat apt to follow the rules laid down by their more noted companions, rather than seek new principles for themselves. Now, however, a German chemist, H. FREUDENBERG, following the announcement of LE BLANC that the point of decomposition of an electrolyte can be sharply determined, has endeavoured to effect the quantitative separation of various metals by submitting their solutions to electrolysis with a definite and constant voltage. As a practical outcome he has found that with a Leclanché cell giving 1·35 volts, silver can be separated from copper and bismuth, and mercury in the mercurous state from copper, bismuth and arsenic, the metals being in all cases in weak nitric acid solution. When the relation of volts to the deposition of a metal from its solution is a little more generally understood, we shall no longer see a distinguished chemist, as actually happened not very long ago, sorely puzzled to find that a single Daniell failed to throw down a trace of copper from a solution of copper sulphate when a platinum anode was used, but deposited it freely when one of copper was substituted.

Bradford.—The Town Council have decided to spend £30,000 on an extension of the electric lighting system.

Nelson.—On Saturday last the work of laying underground mains on the low-pressure system for the Corporation was commenced.

Brighton.—The Lighting Committee of the Town Council have adopted a scheme for lighting a great part of the King's-road and the sea front with the electric light.

Electricity in Newspaper Offices.—The Vienna *Fremdenblatt* is now being printed by electricity. Current is obtained from the mains of the International Electric Company.

Digitized by Google

Barnet.—The Local Board have intimated their intention to apply for a Provisional Order authorising them to supply electricity for public and private purposes within their district.

New Books.—Messrs. E. and F. N. Spon will shortly issue "Household Electric Lighting," by Mr. A. Fahie. The book will be fully illustrated, and consist of about 150 large 8vo. pages.

Ischl.—The town of Ischl, in Upper Austria, is to be lighted by electricity. Water-power will be available. An electric tramway and the lighting of several adjacent places are included in the scheme.

Whitehaven.—It is understood that a letter has been received from the Local Government Board declining to sanction the borrowing of more than £14,000 for the purposes of electric lighting in this town.

Rouen.—According to *La Lumière Electrique* a fire broke out on the 26th ult. in Rouen Cathedral, due to a short circuit on some electric light leads causing a gaspipe to melt, with the result that a beam was fired.

Cambridge.—An accident occurred a day or two ago at the electric lighting works, now in course of construction, by the falling of a quantity of brickwork in the furnace room. Several workmen were more or less injured.

Galileo.—The University of Padua is about to hold a festival in honour of Galileo. The 7th of December, 1892, will be the tercentenary of the day upon which Galileo ascended the chair of mathematics at that University.

Toynbee Hall.—On Saturday last Prof. S. P. Thompson delivered a popular lecture at Toynbee Hall on "Magnetic Stresses," and showed a number of interesting experiments, which were much appreciated by an attentive audience.

The Edison Lamp Patent Decision.—Mr. Edison is reported to be much elated over the recent decision, and is stated to have said that he had always suspected that he was the inventor of the incandescent lamp, but now he was sure of it.

Portsmouth.—Yesterday afternoon the ceremony of laying the foundation of the municipal central lighting station took place, and was followed by a dinner. The scheme adopted by the Town Council has already been described in our columns.

Lancaster.—The Town Council have adopted a report of a sub-committee who, after visiting Bradford, Oxford, and London, recommended the adoption of the low-pressure system. Three companies have been invited to furnish the Corporation with a complete scheme, specifications, and estimates.

Australian Train Lighting.—The Railway Commissioners have recently entered into an agreement with the Brush Electrical Engineering Company to run for six months on the South Australian railways a train fitted with the electric light. The inaugural trip of the train was made last month.

Dundee.—At a recent meeting of the Gas Commission Committee the question of supplying the electric light outside the compulsory area was discussed. The Committee was informed that the Board of Trade had intimated that it could not sanction any expenditure for lighting outside the compulsory area.

Mason College Engineering Society.—The opening meeting of this Society for the session 1892-93 was held at the Mason College, Birmingham, on Wednesday, the 19th inst., when Prof. Robert H. Smith delivered his Presidential address on "Technical Education: Its Use and Abuse, What it Can Do, and What it Cannot Do."

Electric Traction in Brussels.—The Brussels Tramway Company and a suburban railway concern having asked permission to adopt the overhead trolley system of electric traction, committees were appointed by the Ministry of the Interior and the Railway Ministry to consider these applications. Both Committees have reported favourably.

Consolidation of Edison Interests in Canada.—The Edison Incandescent Light Company of Toronto is taking steps to acquire and consolidate under its control the various Edison electrical works in different parts of Ontario. It has purchased already the Edison General Electric Company of Hamilton and the Edison establishment at Peterboro', and will operate them in connection with its Toronto business.

Personal.—Mr. E. R. Dolby has been appointed by the Berkshire County Council to deliver a series of lectures upon "Steam Engines and other Prime Movers, with Special Reference to their use for Agricultural Purposes."——Mr. David Cook, who has for some months past fulfilled the duties of engineer as well as those of manager to the City of London Electric Lighting Company, has been formally appointed engineer and manager to the Company.

The Electric Staff.—According to the *Western Daily Mercury*, the up Cornish express, due at Plymouth at 1:59 p.m., on arrival at Saltash on Monday found its progress blocked, owing to the signalman being unable to withdraw the electric staff. Consequently, he had to telegraph to Devonport, whence a special pilot set out on foot. He was accompanied by an electrician, and on their arrival the staff was taken out. The train, after nearly an hour's delay, was then started on its journey. There were two or three Directors in the train.

Derry.—At a meeting of the Lighting Committee of the Corporation last week it was agreed that Mr. M'Clelland's offer of a site for the generating station should be accepted upon conditions, and Mr. Blake was instructed to prepare plans and specifications for the public lighting of the entire city. It was also ordered that the plans and specifications, when prepared, should be submitted to Dr. John Hopkinson for his opinion on the electrical portion of the scheme, and that a mechanical engineer should be appointed to give his opinion on the steam machinery.

Cables Interrupted.—

Cables.	When interrupted.
Bolama and Bissao (communication with) ...	Sept. 9, 1892
Cayenne-Vizeu...	Sept. 24, 1892
Jamaica-Colon	October 13, 1892
Para-Maranham.....	October 15, 1892
Hong Kong-Amoy.....	October 21, 1892*
Hong Kong-Foochow.....	October 21, 1892*

* Owing to these interruptions telegrams for Hong Kong, Macao, Canton and Manilla can only be sent *vid* India, and telegrams for Shanghai, Amoy, Foochow, and Japan can only be sent *vid* Wladiwostock.

Gilbertiana.—A lithograph facsimile edition of Gilbert's "De Magnete" has just been made in Germany, from the folio edition published in London in 1600. The publishers of this print are Messrs. Mayer and Müller, of Berlin. It is hopeless to expect a lithographic process to reproduce with any crispness the quaint old woodcuts of the original; but the work, such as it is, has been well done. In all known copies of the original folio there exist on page 11 two hand-made corrections of misprints in Greek words occurring in the text. These corrections have not been reproduced in the lithographic reprint.

Atmospheric Electricity.—For some months past M. Mascart has had, says *La Lumière Electrique*, some of his registering electrometers installed on the Eiffel Tower. He does not propose to obtain precise measurements at present, but is only endeavouring to find exactly what use can be made of the Tower for investigations in atmospheric electricity. Under present conditions the instruments are by no means favourably situated for observing the potential of the air; nevertheless, the values obtained are about ten times higher than those obtained at the Parc Saint Maur Observatory, a striking proof of the rapid growth of electric potential with elevation.

Electrical Coast Communication for Life-saving Purposes.—During the recent storm there were no less than three instances in which the telephone lines recently established along the coast proved of service. At Brancaster the lifeboat was called out by a telephone message from the coastguard at Thornham, and saved five lives. At Hunstanton the lifeboat crew were promptly assembled in response to a telephonic message, but the necessary assistance was given by another boat; while at Winterton the telephone was successfully used to secure the services of a tug from Yarmouth to tow out the lifeboat to assist a wreck on the Happisburgh Sands.

The Electrical Utilisation of the Niagara Falls.—Prof. Forbes is reported to have stated in the course of an interview with an American journalist that the dynamos for the Niagara scheme would be the largest that electricians had ever been called upon to design. The Company had signified its inten-

Digitized by Google

tion of putting in dynamos capable of generating 10,000 H.P. each. These monster machines would be constructed entirely from new and original plans. He had received a large number of designs from prominent electricians, but had found none that completely satisfied him. He should probably construct the dynamos on plans of his own in which he had confidence.

Electrical Manufacturing Re-arrangements in France.—At a recent meeting of the Compagnie Electromécanique, which was formed in 1885 by the well-known engine-makers, MM. Weyher Richemond and MM. J. Belleville, and the cable-making firm of Menier, it was announced that the Compagnie Continentale Edison and the Société Heilmann-Brown had given their adhesion, and that the Société Générale des Téléphones would also do so. The object of the Compagnie Electromécanique seems to be to take over that portion of the business of each individual adhering firm which that firm finds some difficulty in carrying on itself. Thus the Compagnie continentale Edison proposes to transfer to the Compagnie Electromécanique all its dynamo-making business, devoting itself henceforth entirely to lamp-making.

An Engineering Tripos.—The discussion in the Senate of the University of Cambridge, of the proposal to found a mechanical sciences tripos for engineering students was, says *Nature*, unexpectedly favourable, in marked contrast to the reception accorded to former schemes. Prof. Ewing is to be congratulated on the skill with which the new plan has been framed, and the success with which he has met and conciliated the original opposition of the more mathematical members of the Senate. The grants for the approval of the plan have been sanctioned by the Council, and it is not likely that they will now be opposed. Some fifteen students are already at work in the engineering laboratory in preparation for the new tripos, which bids fair to take a good place among the honours schools, and cannot fail to stimulate the growth of the engineering department under its present energetic head.

Taunton.—The Directors of the Taunton Electric Lighting Company not finding Mr. Kapp's report to their liking, secured the services of Dr. Fleming, who is of opinion that the system of electric lighting now in operation is the one best adapted to the present requirements of the town; that the plant is in very fair condition, is of a thoroughly good type, and the general arrangements and site of the station have been made with all reasonable forethought for the future. Dr. Fleming also thinks that when the whole of the power available is taken up, and some small additions made, there is no reason to doubt that it will be capable of producing the full output of which it is capable at a cost which will leave a sufficient margin. Having regard to the state of the plant, its original total first cost, and the fact that the proposed purchase price includes the freehold of the land, Dr. Fleming does not consider that the proposed purchase price (£9,300) is an unreasonable figure. If the arc and incandescent lighting is extended to the whole of the streets of the town, and if custom outside by private consumers can be obtained, equal to a yearly demand of 100,000 units, Dr. Fleming thinks that electric lighting might become a source of profit to the ratepayers.

The Electrical Industry in Germany.—The following statistics with regard to the value of electrical goods manufactured in Germany and relating to the years 1890 and 1891 were recently given by the *Elektrotechnische Zeitschrift* on the authority of Herr Fr. Vogel. Telegraphic apparatus to the value of £76,000 was made, telephones over £80,000; railway signalling apparatus nearly £80,000; total, with electric bells, &c., about £400,000. During 1890-91 3,500 continuous current dynamos, alternators, and transformers were built each year, representing £320,000. In 1886 a large German firm built 350 machines, having a total output of 2½ million watts. Last year the same firm turned out 760 machines, the total output of which was 10 million watts, the average size of machine being, therefore, about 9½ H.P. and 17½ H.P. respectively. Accumulators are being turned out in Germany to the amount of £224,000 per annum. About 17,000 arc lamps are made every year, their value being £100,000. The arc light carbon turn-out amounts to nearly £80,000 per annum, whilst that of incandescent lamps totals up to £128,000. The value of the total annual electrical output of all sorts is placed at £1,320,000 or £1,360,000. The number of individuals employed in electrical factories is about 15,000.

Governing Water Wheels.—The sudden variations of load met with in electric tramway work are even more difficult to cope with in the case of turbines than in the case of steam engines. A "Mechanical Engineer" writes to the *Electrical Engineer* of New York, suggesting that the following device should be tried:—Construct a series-wound dynamo large enough to absorb the whole power of the water wheels without injury, and belt it to the main shaft. Build this dynamo so that its critical speed shall be reached when the main shaft runs a few turns above normal, and so that it shall not begin to build up its field until a few turns below it, using "teaser coils" on the fields if necessary. Make the dynamo waterproof, and put it in a tank of water, or put it in a tank of insulating oil, and keep that cool by water circulation. If this is done, commutators and all can be plunged bodily in. The moment cars are thrown off, the main shaft, lightened of its load, begins to speed up, and that moment the series dynamo builds up and puts load on until the total equals the former load, and the shafts keeps its speed. Throw load on the generators and the shaft slows a trifle, when the series dynamo dies out and no load is on the shaft but that of the generators. The output is always the same, but the amount of current from the main generators which passes to line, and the amount which passes to the regulator dynamos and used to heat water are constantly varying—that is all. The idea, of course, is only applicable where water-power is superabundant.

The New Westinghouse Glow Lamp.—The Westinghouse Company has issued the following circular to users of their incandescent lamps:—

In order that no one may be misled by the statements of the owners of the Edison patents with regard to the effect of the recent decision of the United States Circuit Court of Appeals for the Southern District of New York, sustaining the second claim of Mr. Edison's incandescent lamp patent (the other three claims having been held by the Court not to be infringed), we beg to announce to our customers, and to users of incandescent electric lamps generally, that we are prepared to receive orders for the delivery in quantities, after December 1st, of our new incandescent lamps, the manufacture of which has been established at our Pittsburgh factory. These lamps not only do not infringe the Edison patent above referred to, nor any of the patents of other companies, but they are fully covered by patents of our own. The new lamp differs radically from those now in use. It requires no platinum, and is made in separable parts, so that the incandescent burner can be renewed and the bulb and other parts of the lamp used over and over. Furthermore, by means of an important discovery, the burner is rendered stable, its efficiency increased, its life prolonged, and its normal candle power maintained. The manufacture of these lamps will be carried on almost entirely by machinery, and the first cost thereby considerably reduced, so that, with the advantages obtained from the re-use of the bulbs, a saving of from 30 to 50 per cent. to consumers in the cost of incandescent lamps for a given service will be effected. These lamps are in appearance a decided improvement over those now in use, and when used with a new socket designed for the purpose, a further reduction in the cost of lamp renewals will be effected, as no base attachment is required to make the connection with the socket. We are prepared to make advantageous time contracts with the users of incandescent lamps, with important allowances for the return of the bulbs to our factory.

The First Visible Colour of Incandescent Carbon.—Writing to *Nature* on a recent occasion on the subject of the first visible colour of incandescent iron, Mr. T. C. Porter describes how he tried a similar experiment with the carbon filament of an ordinary incandescent electric lamp. For this purpose he employed an 80-volt Edison-Swan 16-c.p. lamp; and the method of heating it gradually was to pass a current, supplied from a battery of accumulators, through the lamp and a water resistance, which latter was gradually reduced by the addition of sulphuric acid. The room in which the experiment was performed was very carefully darkened; and the observers were kept in darkness some minutes before the current was switched on. As the current was increased by regular stages, the observers (25 in number) carefully inspected the lamp in rotation, and every one of them wrote down his impressions of the colour of the filament in the dark, so that their eyes were not affected by extraneous light. Of the whole body of observers, all agreed that the colour of the filament was at first

Digitized by Google

very pale. Thirteen called it a very pale yellow; three termed it white; seven a faint pink; two a bluish white. All agreed, also, that as the temperature rose, the colour grew deeper and redder, passing through orange *before* arriving at crimson. The words used to designate the final tint reached in the experiment varied from deep reddish orange to copper colour, dark red, blood red, crimson. In diffused daylight this would be called a dull red.

The Electric Cars in Boston.—The American electrical journals having done nothing but sing the praises of the electric cars at Boston, a correspondent of our semi-technical contemporary, the *Scientific American*, recently fulminated a vigorous counterblast, from which we take the following extracts: ". . . The facts are that electric cars have been the greatest nuisance that was ever put in the streets of Boston. . . Horses and men have been killed and injured by falling trolley wires, and one of the worst fires in Boston, where three or four million dollars' worth of property and several lives were lost, was set by an electric wire, which was supposed to have come in contact with the trolley system. The telephone system has been greatly impaired by the trolley wires, and accidents have been fearful. . . The capital stock, &c., of this Company has been increased from $6,400,000 to $16,400,000, with debts and liabilities amounting to $20,000,000, in four years. Although they have paid 8 and 10 per cent. dividends on their common and preferred stock, which, of course, has carried their stock somewhat above par, yet, when you consider that in Massachusetts dividends can be paid out of capital stock or borrowed money, it is easy to see how stocks can be sold above par. Outside of those who live a long distance from the centre of the city, and get cheap fares and extra speed in the suburbs, and those who have personal interest at stake, I think the electric road would be voted out of Boston."

The Electrolytic Preparation of Potassium and Ammonium Persulphate.—A memoir upon persulphuric acid and the persulphates is contributed by M. Berthelot to the last number of the *Annales de Chimie et de Physique*. To M. Berthelot is due the honour of the first preparation of persulphuric acid and its anhydride. The form of electrolytic apparatus which has been found by M. Berthelot to yield the best results consists of a double cell, the inner vessel of which is constructed of porous porcelain. The liquid contents of both the interior and exterior vessels are cooled by means of glass worms, through which a constant current of cold water is maintained. The inner cell of 150 c.c. capacity contains a concentrated solution of potassium or ammonium sulphate as required, in sulphuric acid diluted with six or seven times its volume of water. The nearer the composition of this liquid approaches to that of a solution of bisulphate of potassium or ammonium, the greater is the yield of persulphate. The exterior cell is filled with dilute sulphuric acid. The positive pole in the interior cell is best formed by a platinum wire, about one millimetre in diameter; persulphuric acid is found by M. Berthelot to be rapidly decomposed in contact with a large surface of platinum. Platinum sponge instantly decomposes the acid or solutions of its salts. The negative pole in the outer cell may conveniently take the form of a large plate of platinum. The current employed was three amperes. After about 15 to 20 hours the internal cell was found to contain large quantities of crystals of the persulphate. The usual yield of the potassium salt was 20·25 grammes, and of the more soluble ammonium salt as much as 40·45 grammes, in one operation. M Berthelot has also obtained potassium persulphate by the direct electrolysis of sulphuric acid and subsequent addition to the product of a concentrated solution of potassium bisulphate, crystals of potassium persulphate, KSO_4, being at once deposited. This mode of preparation is not so advantageous as the method o production by the electrolysis of potassium sulphate as above, but affords interesting proof of the formation of free persulphuric acid by the electrolysis of sulphuric acid.

The Dielectric Constants of Conducting Liquids.—In the *Journal de la Société Physico-Chimique Russe* (Vol. XXIII.) W. Stschegtiaff gives the results of some determinations by him of the dielectric constants of conducting liquids. To avoid the errors caused by absorption and the conductivity of the dielectric, it is necessary to use electrical oscillations of as short period as possible, or to arrange the experiment so that the errors mutually compensate each other. The author preferred the second method. The condenser was formed of three disks, two of which were fixed vertically at 5 millim. from each other, and the third could be displaced parallel to itself, this latter and one of the two fixed disks were connected with the electrodes of a Ruhmkorff, while the central disk was put to earth through a sort of Geissler tube formed of a small 5-volt incandescent lamp, the filament of which had been broken by too strong a current. This apparatus placed quite near the disk was extremely sensitive to electrical oscillations, the presence of which was shown by a light like that of Geissler tubes, while the static discharge of the condenser produced a spark. If the two extreme disks were not arranged so as to form two condensers of equal capacity with that of the middle, this latter was charged and the lamp was illuminated; by varying the distance of the movable disk this light could be annulled; it reappeared when the desired position had been passed. In order to diminish this error the mean a of the two distances was taken. If between the two stationary disks of the condensers a layer of a dielectric of thickness d is interposed, the constant of which is D, the movable disk must be displaced through a length x in order to make the light disappear. We have the equations

$$a - x = a - d + \frac{d}{D}; \quad D = \frac{d}{d - x}.$$

The liquids were placed in a glass trough with parallel sides. The results obtained are in agreement with Maxwell's law: $\sqrt{D} = n_\infty$.

Fly-Wheels.—By an accident at the station of the Sioux City Electric Light Company, says the *Western Electrician*, all the lights in that city were instantly extinguished on the night of September 22nd. The accident occurred to the centre engine. The wheel, 11ft. in diameter and weighing 3 tons, was running at about 210 revolutions, when the belt leading from it came off. The wheel, relieved of its load, tore round at an alarming rate. The belt was thrown about, and, catching in the machinery of the engine, tore the governors off. The engine then went beyond control, and the wheel tore through the air at such a rate that it fairly churned the air in the room, tool-boxes, chairs, &c., whirling in every direction. Finally, the wheel burst with a loud report. Four pieces went up through the roof, 30 feet above. Two pieces, weighing upwards of 100lb. each, flew off to the north of the shafting. One struck the heavy brick wall about 5 feet above the floor and tore a hole completely through it. The other struck the wall nearer to its base, and its force was only sufficient to drive it about half through the wall. The force of the pieces flying off to the south of the wheel was broken by a large fender built around that side of the wheel to protect it. The fender was torn to pieces, and one of the pieces struck an iron steam pipe about a foot in diameter, and protected by heavy lagging. The piece tore a hole through the pipe. Another piece found its way up among the wires in the roof and short-circuited the dynamos supplying the arc circuits. This sent off the shaft wheels in another part of the station, and another huge belt slipped off, but fortunately did no damage. In the meantime the great belt on the shaft of the centre engine was being whizzed through the air. Every time it was carried down into and out of the wheel pit it struck the floor and dashed the boards nearest it to splinters. The flooring for a considerable distance from the wheel was torn up by the belting. Andrew Belt, one of the engineers, who was working near by when the belting came off, made a race through the shower of splinters for the cut off valve and succeeded in reaching it and cutting off steam. During all the time he was in the room the steam was escaping from the hole in the steam-pipe.

SOME OF THE USES OF SEARCH LIGHTS.

BY R. H. BACON.

The various accounts of the several manœuvres of late years, when touching on the subject of search lights, have more or less left a general impression of their inutility. Correspondents on both sides of the opposed forces have freely criticised them, and most naturally so, since experienced torpedo boat officers do not consider them a formidable deterrent, and the authorities in the larger ships are sceptical as to their utility as a means of warding off a torpedo boat attack. Without in any way being dogmatic, it may be confidently asserted that considerable judgment is required before using a search light as a means of defence from a torpedo boat attack. It will be as well in explaining the peculiarities attending the practical use of the search light on board ship to consider the conditions by which a boat becomes visible by night.

Objects on the water or against the horizon are visible solely by the contrast of their colour or shade with that of their surroundings. Were the object exactly similar to its surroundings, naturally it would appear but as part of them, and be invisible. In bright sunshine it is impossible to imitate water so exactly in its varying colour and shades as to render a boat absolutely invisible upon it; so much light is always present ready to be reflected from all parts of an object that slight variations are easily detected, but at night this is different. Smooth water at night, when lit up by a search light, appears very dark indeed, and naturally so, since to an observer near a projector but few rays are reflected back from the small ripples; the water, therefore, appears almost black. Now place on this an object which also reflects but little light to the observer, such as a "dead" black boat (one painted with black lead), and the contrast between the two is almost *nil*; in fact, so nearly may the two sets of reflected rays match one another as to leave the boat, though in the centre of the beam, practically invisible from the ship. It is not sufficient to merely let the beam fall on the boat, but to see it it is necessary to produce a distinct difference between the light reflected by the boat and that reflected by the water. This at once explains a very common occurrence to all who have taken part in night attacks—that is, to find your boat brilliantly lighted by a search light beam, and yet for the beam to pass by harmlessly without the boat being observed by the ship. Nor is this all. Observers on board the ship are to a certain extent dazzled by the brilliancy of the beam even when at some considerable lateral distance, since the particles of moisture or dust in the air reflect and diffuse light to a considerable extent, and an effect is produced similar to, but, of course, to a less extent, of looking out of a light room into a dark night; the exact extent of the effect is determined by the angular position of the observer from the projector and object. There is yet another effect that limits the distinct vision of an observer near a projector, and that is the fact that when near a projector the rays reflected from an object have to travel back for some distance through the beam—that is, they suffer from considerable interference. The result is that the object appears indistinct. It will be easily seen that all these effects greatly reduce the efficient use of a search light when used to pick up an object if the observer is placed near the projector, as is usually the case on board ship, especially when the object is travelling towards the ship at a high speed. The practical proof of this is shown by the fact that a boat is rarely *itself* recognised in the first instance at any great distance, but originally attention is attracted to her by her bow wave—that is, the wave of foam, which reflects a comparatively large amount of light, and shows up distinctively against the surrounding dark-coloured water.

Were the above case, viz., that of detecting boats from a ship by means of a search light *in* the ship, the sole use of that weapon, it might, indeed, be an open question whether the electric beam is any material good in naval warfare, for there is one point which must never be forgotten, and that is, that the fact of burning such a light reveals the position of the ship to an attacking boat, when, by an absence of all lights, the darkness of the night might be a more efficient protection. It is this particular case which is the one that correspondents in manœuvres are most frequently brought into contact with, and on it opinion is so much divided that in open water it is probable that no captain would promiscuously use his search light as a method of defence. Happily, however, other occasions arise in war time when the search light is of great value. These may be divided roughly under two heads—(1) Defence of a fleet in close waters, where the position of the anchorage water of itself reveals the probable position of the fleet; and (2) Fleet action at night, or action between single ships.

Regarding (1) the case may be briefly stated as follows:—Ships are at anchor in a close anchorage for some particular reason, either for repairing or refitting purposes, or else the close presence of a superior force. For it is inconceivable, considering the deadly nature of a torpedo boat attack, that an officer would keep his fleet at anchor at night in a harbour that afforded by its position a possibility of an attack from torpedo boats if he could possibly avoid it. Supposing such the case, the search light may be a most efficient help against such an attack. Light may be burned at a distance from the ship on shore to light up the entrance or different sections of the passages through which the torpedo boats will have to pass, or the ships may illuminate the passages and use observers in their guard boats. In either case the effect is the same, for no longer has the light reflected from the attacking boats to be reflected at a small angle to the observer, but the observer is placed in a far better position as regards reflection, and far more minute differences in shade can be observed, since the reflected light is much greater. In other words, a greater contrast is produced between non-reflecting bodies and the water—gun fire can, therefore, be more effectively used, and greater havoc effected on the attacking force. In such a case, one thing is certain, for *detecting* boats all beams must be fixed so that observers may get their eyes accustomed to a constant intensity of light, and not a variable one, as produced by "sweeping" beams. This is the most effective use of an electric search light. A few beams may, of course, be kept in reserve for following up and illuminating boats after they have been detected, but these should be quite independent of the fixed beams. The guard boats, some two thousand yards away, can see the approach of others several hundred yards off, since the surrounding water is well illuminated by the beams of light playing on it. When the boats are discovered, it is necessary to light them up sufficiently for the guns' crews in the ships or boats to use their guns. This may be done by the ships' projectors with divergent lenses in conjunction with parallel beams, the divergent lenses being used to light the boats up, and from their large divergence prevent the chance of losing sight of them again, and the parallel beams to more brightly illuminate them and make them more clear to the guns' crews.

Again, in single ship or fleet action at night, search lights must be used to light up the enemy, and now the search light is no longer an objection, as showing the position of the ship, since its height prevents an accurate estimation of the position of the waterline (the most vulnerable position in the ship to fire at), but in reality it is absolutely safeguard, both since it is misleading as to the distance of the ship, and also is blinding to the opposing guns' crews. From the foregoing remarks it will be seen that the function of the search light may be either to *discover* or to *light up* an object for guns to fire at. These two different uses are important, since they lead to the height of the light being varied to some considerable extent. It has long been the opinion that for discovering boats the beam should be low, since its direction is parallel to the surface of the water, and, therefore, lights up a larger area than would be the case if thrown down on the water from a height, when the plane of the water would cut the beam in an ellipse whose area depends on the inclination of the beam. But a little thought will show that if the beam be parallel to the water the water is but feebly illuminated, whereas a body, vertical to the water, cuts the beam at right angles and receives a large amount of light. Were the body absolutely non-reflecting, it would be invisible; but if reflecting, a contrast will be obtained. Now that boats can be painted so as to be practically non-reflecting, the low beam is viewed with more disfavour, especially as *detection* is not the chief function of a light in a ship. The real function of the light *on board* is to light up an object

whose approach has been detected, so that the guns' crews can accurately lay their guns. To do this it is necessary to keep the light as far from the guns as possible, and also to keep the beam off the water near the ship, so as to prevent the men being dazzled. The best position in the case would appear to be to have the light above the guns, so that the crews practically do not see the beam, except where it strikes the object, and also should the opposing ship use the light to aim at the shot will be more likely to pass over the ship. Another great point is to have the projectors so placed as not to illuminate any portion of the side or superstructure of the ship; this, again, is best obtained by a fairly high position of the light.

For attacking forts or in action in moderately smooth water a light in the military tops would seem to answer these requirements; but, of course, with even a moderate motion of the ship a beam from a projector so placed would sweep through a far larger arc than one in a lower position, and would, therefore, be far harder to keep steadily illuminating an object. For navigating purposes, where the water close to and for some distance ahead of the ship has to be illuminated, a low position of the light is best.

For signalling purposes, at night a beam may be thrown on a cloud, and its reflected light will be seen at considerable distances; the distance, however, depends on the height and position of the cloud, and a general rule as to visibility cannot, therefore, be even approximately laid down.

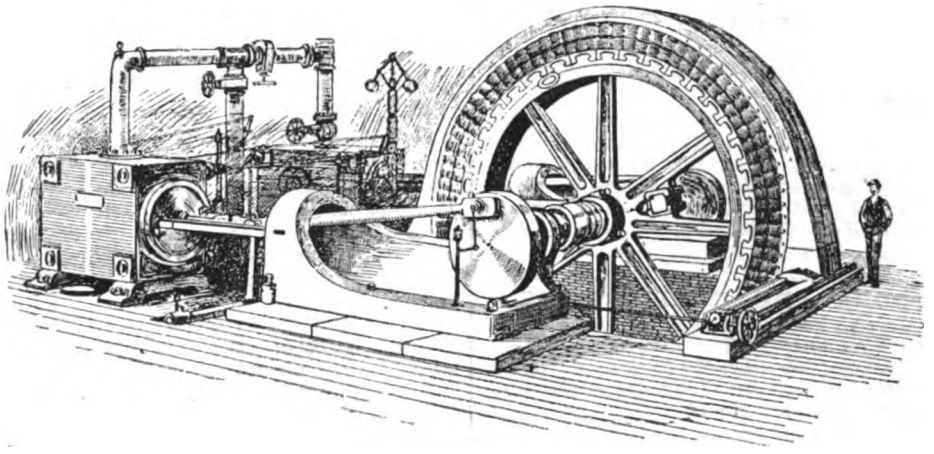
In this short article many points have been intentionally omitted. The position of observers has no interest except to those technically connected with the service. Automatic lamps and projectors, though of great importance, are beyond the scope of the present outline, which is only intended to point out a few of the many difficulties and problems that arise in the practical use of the search light. So much criticism on the lights has been passed in late manœvures, that it is only fair to point out that isolated uses of the light in manœuvres (and those generally in one particular and that the most inefficient occasion, viz., the detection of boats) are not the sole uses, and that, therefore, it is unfair to judge of the importance of the light to the navy by them. Our material is excellent, thanks to the makers; we cannot say the best, since the best is never arrived at, and all things improve day by day, but the failure of the light to do all that we wish is rather our own faults for expecting it to fulfil the condition of daylight, when after all our 5,000 watts can but give us a definite amount of light which in its turn has to obey the inexorable laws of optics.

A LARGE WESTINGHOUSE ALTERNATOR.

In the station of the Narragansett Electric Lighting Company, of Providence, R.I., two large dynamos are in the process of erection. One is being constructed by the General Electric Company, and the other by the Westinghouse Electric and Manufacturing Company. These generators have each a capacity of 500 H.P., and are direct driven at 90 revolutions per minute by a cross-compound automatic cut-off steam engine of special design, built by the E. P. Allis Company, of Milwaukee, Wis. These engines are alike in size; the high-pressure cylinders are 19in. in diameter, and the low-pressure cylinders 36in., with a stroke of 48in. The cylinders are steam jacketed. The two engines are set in the western portion of the engine house, and rest on a foundation about 50ft. square. Large granite stones were bedded into the brickwork foundation where required, the top stones being faced off to receive the engines.

The Westinghouse generator, an alternator, is nearly completed, and it will soon be in operation. A good idea of its construction may be obtained from the accompanying illustration, which we take from the *Electrical World*. In this case the armature is actually built upon the original flywheel of the engine. The 80 coils are wound on lathes and slipped into place. The cores are made up of thin plates of special iron, some 60,000 of these plates being used in the construction of the armature and field. A device is provided for moving the field to one side away from the armature, so as to give free access to all parts of both.

The current is taken off by large brushes from ring collectors upon the shaft. The field is excited partly by a separate machine, and partly by a current from the dynamo itself. The number of alternations is 120 per second. This machine is guaranteed to deliver 373,000 watts, with a maximum rise in temperature not exceeding 54° F. above the surrounding air. An efficiency of 92 per cent. is guaranteed, but it is expected that the actual commercial efficiency will be about 94 per cent. The following dimensions give some idea of the size of this machine:—The foundation space occupied is 42ft. by 21ft. 6in. The outside diameter of the field is 19ft. 7¾in., while the diameter of the flywheel is 16ft. The weight of the armature and of the field complete will be about 90,000lbs.



New 500 H.P. Westinghouse Alternator.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, October 28th.

PHYSICAL SOCIETY.

5 p.m. Paper to be read: "The Determination of Critical Density, Critical Volume, and Boiling Points," by Dr. Young and Mr. Thomas, to be discussed together with the Paper on "The Laws of Molecular Force," by Mr. Sutherland, and "The Dimensions of Physical Quantities," by Mr. Williams.

OLD STUDENTS' ASSOCIATION.

7.30 p.m. Annual Dinner at the Holborn Restaurant.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at St. James' Hall Restaurant.

FRIDAY, November 4th.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Presidential Address by Dr. John Hopkinson, F.R.S.

For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Phillippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 2s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Nearly ready.*

DRUM ARMATURE WINDING, AND COMMUTATORS: In Theory and Practice. By F. M. WEYMOUTH. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRICITY AS A MOTIVE POWER. By A. T. SNELL. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

FULL CATALOGUE POST FREE ON APPLICATION.

SPECIAL NOTICE.

With this issue of "THE ELECTRICIAN" is published a STEEL-PLATE PORTRAIT of the late CYRUS W. FIELD, Pioneer of Ocean Telegraphy.

A few copies will be printed on India Paper, and will be forwarded post free on roller, price 3s. 2d. per copy; ordinary copies of the Portrait, post free, 1s. 2d., or framed in Black Pillar or Brown Ornamental Frame, price 4s. 6d., carriage extra.

Subscribers to "THE ELECTRICIAN" *should receive this Supplement Gratis, and complaints of non-receipt should be promptly addressed to the Publisher of* "THE ELECTRICIAN."

Prospectus of "THE ELECTRICIAN" *Series of Fine Steel-Plate Portraits (13 in all) post free on request.*

The present Number of "THE ELECTRICIAN" completes Vol. XXIX. With next week's number will be issued (Gratis) the Index to the Volume.

READY NEXT WEEK.

Volume XXIX. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

NOW READY. Cases for binding Volume XXIX., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

COMMERCE AND COERCION.

At the thinly-attended meeting at Botolph House on Friday last, the subjects discussed afforded some interesting examples of coercion. In the first of these it is true, coercion was abortive, but if a fair number of members had thought it worth while to exhibit at Chicago, many others would have been forced to do the same. The only symptom of coercion in this instance was the record of the withdrawal of the rule which forbade the display of duty-free prices. This subject having been dismissed, the old question of overhead wire regulations came up again. This has been discussed so fully in our columns that it is quite unnecessary to go into details, but attention may be drawn to the fact that more than three years have now elapsed since these rules were issued. It is said, but not officially we believe, that these rules were provisional, and we are glad to learn that a committee of the Institution of Electrical Engineers has been appointed to consider the matter. It would be a great pity if the Institution were to take up an anti-commercial attitude when questions of this kind are laid before it. When the London Chamber of Commerce invited this body to take joint action in connection with Electrical Standards, and the establishment of a Board of Trade Laboratory, scientific niceties

Digitized by Google

seemed at one time to be opposed to commercial considerations; but as soon as the intentions of the Government Department were understood, the professors were left to deal with their definitions. Scientific refinements in connection with overhead wires have led to ridiculous results, and the whole question of sparking distances which then determined the thickness of the insulation, has been thoroughly investigated since the promulgation of the rule of thumb standard of a twentieth of an inch for every thousand volts. Regulations of this kind made, perhaps, in haste or with too much caution, can be modified after three years' trial, but to complain that there are signs of over-regulation and interference in the future is another matter. Hitherto the Board of Trade have sought the advice of the Institution of Electrical Engineers on technical details, and if, as it happens, the active members of the Council consist of professors and consulting engineers, with only a small minority of men engaged in trade, say half-a-dozen out of thirty-three, it would be only fair that when a trade matter arises, the Electrical Trades Section of the London Chamber of Commerce should have, not an exclusive, but an equal hearing with the strictly scientific body. But when it is said that there was never any intention on the part of Parliament that the Board of Trade should have power to regulate operations of electrical contractors in detail, it must be remembered that we have entered upon an age of regulations; some petty, some preposterous; and if the electrical trade is to be subject to any authority, it can be in no better hands than those of the Board of Trade. On a former occasion we expressed a wish to see an electrical department fully equipped and comparable with the other practical branches of this office. In whatever direction the Board of Trade may stay its hand, there assuredly will the County Council step in; at all events where London is concerned. And if such withdrawal from responsibility is encouraged by an outcry about over-regulation, an excellent example of King Log and King Stork will be afforded; with this difference, that the modern meddler is impelled by zeal of reform and thirst for economies, while his prototype frankly confessed that he eat the frogs because he liked them.

Having settled this bit of coercion for the present, by the appointment of a committee, from whose exertions emancipation or relaxation of the obnoxious rules is hoped for, the meeting went on to listen to three propositions for the self-imposition of restrictions and prohibitions, which if suggested by any outside body would be received with a storm of denunciation. Students of human nature will note that when it comes from within, the more proscriptive the ordinance, the less indignation it arouses; and when matters reach a climax of coercion, the question simply ceases to arouse discussion. The first of these proposals was one which claimed the attention of the Electrical Trades' Section at its first meetings, and a committee, consisting if we remember aright of the whole of the manufacturing members, was appointed to consider it. The standardising of machinery sounds well, and we may point with pride to our $\frac{7}{8}$in. lamp caps, which fit all B.C. sockets to a nicety, compared with the clumsy taper-thread expedient of the common gas burner. The B.A. screw-thread has been successfully introduced, and at one time it was hoped that the frequencies of alternators might be systematised. But the present proposition seems to be concerned chiefly with speeds, voltages, sizes of machinery, and insulation of cables. Of these, the question of voltage is comparatively simple, and Major Flood-Page so far forgot his habitual caution in questions of lamp making as to confide to the meeting his anticipation that lamps will be divided into two classes, lamps for supply systems, and others. This may be taken to mean, we suppose, that 100-volt and 50-volt lamps will be cheaper than lamps of fancy voltages. The only excuse for using other lamps is the custom of running arc lamps in parallel at 60 or 70 volts, though the best lamps are now made to run on 50 volts; and the standard of the Navy where 80 volts have been adopted. This proposed difference in price is very natural, but it will tell hard on the unfortunate townsfolk of Brighton and Bradford for whom meters have to be specially rewound, since their supply is fixed at 115 volts. The Board of Trade, before sanctioning such fancy standards of pressure, might suggest to the local authorities that such a departure from the established practice is likely to be troublesome if not unnecessarily expensive.

The uniformity of speeds and sizes of dynamos is but a single question, and appears not only hopeless to attempt, but ill-calculated to produce "much larger margins of profit, which, after all, was the point they were all aiming at." The speaker suggested that if an account of the distinct types of machines of the several manufactures in England were drawn up, that members would be surprised to find the enormous number of varieties therein contained. Such a list is readily found in "*The Electrician* Electrical Trades' Directory," and the result is simply expressed by the statement that last year there were 4 firms who offered more than 20 sizes of machines, 8 who offered more than 15, and 11 with more than 10, making 249 sizes in all of continuous current dynamos only. By sizes we mean separately marked types in the catalogue. Some of these are almost identical but for an alteration of speed. But one aspect of this splendid choice is that the purchaser has a magnificent assortment to choose from, while one manufacturer at least will be able to "fill the bill" from stock. Purchasers, however, were scarcely mentioned at Botolph House, and it was the consulting engineer who was blamed for specifying one particular speed when some unhappy maker could have supplied a dynamo to do the work, if allowed to run a little faster. A specification rarely defines a speed, but sets a limit beyond which the dynamo-maker must not pass. Nothing is said about slower speeds, unless the engine-maker is concerned. In Admiralty work, where weight is of importance, and where the engine-maker sometimes claims greater consideration, it is he who sets the lower limit, below which he cannot supply the power, while the obvious conditions of the work define the maximum speed. The narrow range thus allowed has called forth the greatest skill in dynamo design, and has put the whole art on a far higher level than where a dozen standard sizes alone are made. We grant that a scheme of standard sizes looks at first glance attractive, but if adopted by the leading manufacturers —a manifestly absurd idea—what coercion is to prevent a new maker from proposing to build a machine to suit any specification; and, after all, was not this the origin of a large majority of these various types? We cannot go into the question of cables. Let the cable-makers first prepare a standard list in which a 300 megohm insulation shall, for want of a better designation, denote a particular quality; we may then judge whether this is good enough for any particular purpose; but at present the 2,000 megohm quality of one firm is little, if any, better than the 600 or even the 300 megohm class of another.

On the diversity of prices in tendering for the same work we have often commented; the best cure is the very bit of coercion about which complaints have just been made, viz., a strict specification. The sixpenny telegram and the other examples of uniform prices given to the meeting were no examples at all, and "to bring a certain standard of work into practice, and to get nearer to a uniformity of price for that standard," belongs to

Digitized by Google

the visionary Utopias of speculative socialism. The question of tenders in connection with specified speed has a bearing on the important question of the rights of the lowest bidder, and on one branch of this subject an interesting article, reproduced from a contemporary, will be found in another column. If a maximum of 500 revolutions per minute be specified, and a first-rate dynamo maker offers to supply a machine, perhaps at a reasonable price, but at 510 revolutions, according to one notion, the fad of the consulting engineer ought to give way; but is this just to all the other contractors who are prepared to do that which has been asked? A Paper might with great advantage be read by some experienced contractor before a meeting of the Electrical Trades Section and perhaps other sections of the London Chamber of Commerce, and followed by a discussion. Such a Paper, which would be altogether out of place at the Institution of Electrical Engineers, would probably draw a good audience; it being understood that any member using the word hysteresis or lapsing into mathematics would be at once ejected.

The last proposition submitted to the Section at Friday's meeting was, perhaps, more suited, in the present state of the question, for rhetorical sparring at a debating society than for a meeting of business men. For many years no politician has wasted words about Protection; for one party this would have been but to flog a dead horse, the other party dared not mention it, and rash outsiders who disparaged free trade were told that "that cannot come up at this election." Tariffs are, however, a common topic to-day, but as politics must be excluded from these columns, we would merely ask by what process of coercion is a gallon of lubricating oil (not the containing vessel) to be stamped or branded with the proposed British trade mark.

CYRUS W. FIELD.

We issue with the present number a steel portrait of the late Mr. Cyrus W. Field, who may justly be described as the Pioneer of Ocean Telegraphy.

Having shortly after his death given a notice of the principal events of his life (vide *The Electrician* of July 15, 1892), it is not necessary here to go over the same ground, but we find that, in the opinion of those who knew the late Mr. Field best, adequate justice has not yet been done to the magnificent energy and irrepressible perseverance with which he toiled almost day and night for many years until, after frequent failures and crushing disappointments, which would have shaken the courage and endurance of almost anyone but himself, the object of his life was accomplished, and electrical communication between the Old and New Worlds was established, which, with ten cables existing in the North Atlantic alone, is not likely ever to be severed, even temporarily. A characteristic instance of his undaunted attitude, in face of misfortunes which seemed to augur the final failure of the enterprise, was afforded in the case of the second expedition. When the cable parted and his colleagues in the great work were considering whether it were possible to recover the cable, Mr. Field, after retiring to his cabin for a time, reappeared with a draft prospectus in his hand, designed to secure the capital necessary for the laying of a new and improved cable!

As showing the extent to which the enterprise dominated his mind, it may be mentioned that in one of his speeches the late Mr. Field said he had frequently prayed that he might be spared until sub-Atlantic telegraphy had been accomplished, and there is no doubt that, having once entered on the undertaking, he devoted himself and all his inexhaustible energy to the carrying out of the task, neglecting his private affairs, and giving neither himself nor anyone else who might help in the work any rest until success was attained. It is not too much to say that but for his unwearied persistence Atlantic telegraphy would have been postponed for several years at least, and that the world-wide system of submarine cables would not be so extensive and complete as it now is.

The steel plate portrait which accompanies the present number was engraved from a photograph of the painting of himself presented to the late Mr. Field in public acknowledgment of his services to the world in the cause of ocean telegraphy, and is a very faithful reproduction. Mr. Field was born at Stockbridge, Massachusetts, U.S.A., in 1819, and died at New York on July 12th last.

GEARING.

BY E. TREMLETT CARTER.

(*Concluded from page 668.*)

Helical Gear.

We have seen that one of the most serious objections to the ordinary form of spur gear is the irregular running caused by the drop of the teeth on to one another as they come into gear. The greater the pitch of the teeth the more drop will occur, and even with the best form of teeth it is impossible to altogether eliminate the vibration which ensues. In certain classes of electrical work it is impracticable to permit these vibrations, while at the same time it is desirable to have a more positive form of gear than is found in those kinds which depend only on a frictional grip. Such a form is found in helical

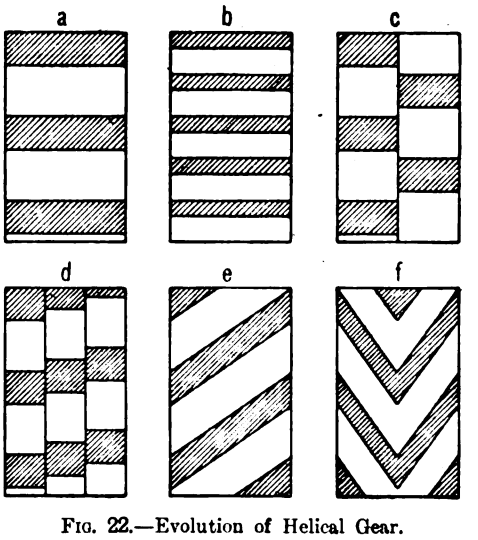

FIG. 22.—Evolution of Helical Gear.

or screw gear. The action and evolution of this gear is explained by the series of diagrams in Fig. 22. At *a* there is an ordinary spur gear; the teeth, having long pitch, being shown by the shaded portion. The drop in these teeth would be very large, but it might be reduced by having a gear shown at *b*. In this the pitch is reduced, and the number of teeth increased in proportion; the frequency of the teeth coming into gear being doubled, there would be only half the drop with each tooth. But, the thickness of each tooth being reduced to one-half, the strength will be reduced to one-quarter of the former value, a contingency which would probably render *b* useless. It is possible, however, to increase the frequency of the teeth without reducing their thickness; and a form of gear which will do this is shown in *c*. Here one-half of each tooth is displaced forward by an amount equal to half the pitch, the effect of which is to cause the right and left halves to come into gear alternately, and to double the frequency and halve the amount of drop. By having three sections to each tooth, and displacing each section forward by one-third of the pitch, as shown at *d*, the frequency may be trebled, with the result that still less vibration will occur. Now, it occurred to Dr. Hooke, the inventor of helical gear, that by having an infinite number of sections, and displacing each section an infinitesimal amount forward, the drop should be entirely eliminated, for there would be always some portion of some tooth in gear. Such an arrangement would form a slant tooth as

Digitized by Google

shown at *e*, and since such a tooth would really be a part of a screw wrapped round the wheel, the name helical or screw gear has been given to it. The slanting surface of the thread or tooth at *e* would set up a reaction in the direction at right angles to the motion of the wheel, causing an injurious side thrust on the wheel and an end thrust at the bearings. To obviate this, one-half of the thread is slanted in an opposite direction to the other half, the threads being right and left-handed. The thrust due to each half of the gear will balance that due to the other half, and thus, though there will be a bursting stress on the material of the wheel,

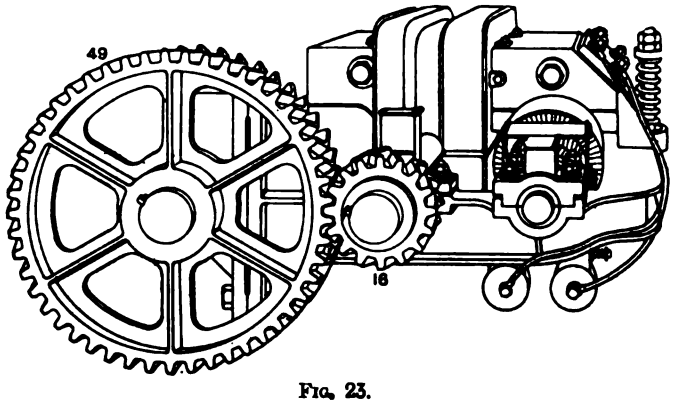

FIG. 23.

there will be no end thrust at the bearings. Owing to the advantageous position of the material as it takes the pressure of the thread in which it is in gear, the strength of helical gear is 20 per cent. stronger than spur gear of the same pitch and material. In regard to its regularity in running, it is said to be smoother than morticed gear and to be as silent as belts or ropes. It is doubtful whether this gear can be adapted to traction work, owing to the necessity for strict parallelism and relative position of the wheels; but it has been successfully applied to motors for pumping, haulage, and mining work. The manner of fitting helical gear to an electromotor is shown in Fig. 23, in which a pinion of 16 threads on the countershaft is geared into a wheel having 49 threads on the machine shaft. The first motion gear on the opposite side of the motor, is not shown.

Chain Gearing.

The well-known bicycle chain gear has been several times tried in connection with electric traction work, but has not

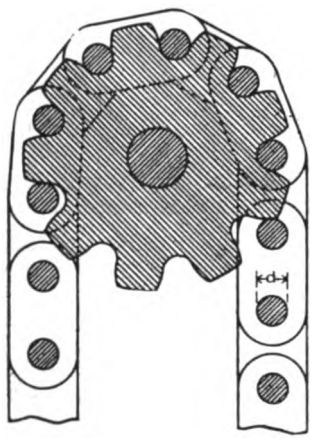

FIG. 24.

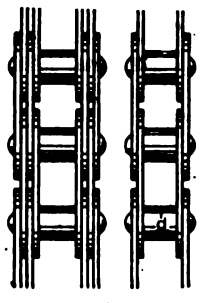

FIG. 25.

proved successful where much power is to be transmitted by it. Difficult to design and construct so as to be efficient and durable, and troublesome in working, this form of gear has only its positive grip, and the flexibility which permits of considerable relative movement in the shafts to recommend it The construction of the most common chain is shown in Figs. 24 and 25, the former showing the side view of the chain and chain wheel, and the latter showing how the chain is built up. The links are formed of a number of flat strips of steel plate, composing two sets of alternate links by being riveted on to a number of steel spindles. The spindles are turned to a shoulder at the links, being 20 per cent. thicker in the middle portions, and the heads fit sufficiently loosely for the links to have free motion in the plane of the chain. In many cases the middle part of each spindle is loosely covered with a steel thimble, which provides a rolling instead of a sliding motion as the chain gears with the teeth of the wheel. Each link is usually composed of two or more strips in parallel; but the strength of the chain cannot be indefinitely increased by adding strips, for when the thickness of the compound chain has reached a certain value the flexure of the spindle end will set up a compressive stress on the outside strips, rendering the chain actually weaker than a narrower one would be. Nor can the strength of the gear be very much increased by increasing the depth of the chain, for this would necessitate long and fragile teeth; it would also produce inefficient running, on account of the increased friction between the chain and the wheel. For these reasons the material of the links must be worked with a small factor of safety, and the result is that the links rapidly stretch, and the chain no longer gears well with the wheel. To partially prevent this, the links are sometimes made numerous and very short; but even here there is a limit in the reduced thickness of the teeth. Owing to the flexure of the spindles the inner strips are subjected to more stress than the outer, and are sometimes made thicker; with two strips, for example, the stress on the inner one is 90 per cent. of the total pull on the chain. Prof. K. Keller, who has investigated the best conditions for this gear, recommends the following proportions:—Taking d as the diameter of the spindle inside the strips, the diameter of the mid portion of the spindle should be $1{\cdot}2d$, and the width of this thickened portion should be $(1{\cdot}7d + 0{\cdot}2)$. The outside measurement of the link should be $2{\cdot}5d$ wide, and the pitch (from centre to centre of spindles) should be $2{\cdot}9d$. In order to prevent variation in the stress on the chain the number of teeth on the wheel should never be less than five, and is preferably eight or more. Wheels with four teeth have been tried, but the variation in load on the chain was found to lead to rapid deterioration.

This form of gear has been tried on the Berlin-Lichterfeld electric tramcars, and on some cars designed by Mr. Reckenzaun in London; it is also in use in America on cars designed by Van Depoele. At Berlin it was found that the gear, which replaced the steel spiral cord gear described in a former section, resulted in considerably reduced speed in the cars, but that it was able to take the cars up a steeper gradient, and to start them more quickly. The gear, however, ran very noisily, and with great vibration, as was also found to be the case in the London cars.

ELECTRIC LIGHTING AT HAVRE AND BOULOGNE-SUR-MER.

The Central Station of the Société l'Energie Electrique at Havre is a substantial brick building containing the usual offices, workshops, and stores, and is situated close to the railway station, lying between it and the coal dock, where all the coal ships are discharged. The power for driving the dynamos is supplied by two large single-cylinder Corliss engines, constructed by MM. Farcot, each capable of developing 450 I.H.P. The number of revolutions per minute is, under the ordinary working conditions, about 55. The fly-wheel weighs about 15 tons, and is 21·7ft. in diameter, with 10 grooves in the circumference, in which run the cotton ropes driving the dynamo. Each engine has an independent air pump and condenser, but if necessary the steam can be exhausted direct into the atmosphere, and the boilers fed with fresh water from a tank supplied by the water mains of the town. The water for condensing purposes is drawn from the dock. The boilers are five in number, and of the Berendorff type, with 1,750 square feet of heating surface each. There are two 244-kilowatt Ferranti dynamos, but under ordinary working circumstances they only give out 100 amperes at 2,400 volts. The collectors, method of oil circulation, and other details are all of the usual Ferranti type and do not call for any special remark. The current, on arriving at the

Digitized by Google

switchboard, passes a large Ferranti fuse, voltmeters, and small double-pole switches of the same type that are used with the small transformers employed in the houses of the consumers. The board is also fitted with a Thomson electrostatic voltmeter, a Carpentier voltmeter, a Thomson ammeter, and three large commutators, which enable the various circuits to be switched on to either machine. A Richard registering ammeter shows that the maximum output is registered between 5 and 7 p.m. There are also two Cardew voltmeters, and the necessary resistances for the exciters.

The cables have sections varying according to their position in the circuit and are of 0·0108, 0·02015, 0·0434, 0·0868, and 0·1736 square inches section. The main circuits are two in number and are each capable of carrying 100 amperes, *i.e.*, 240,000 watts, which is equivalent to 6,500 lamps of 10 c.p. each. The mains are composed in the centre of tinned copper wires, surrounded with a layer of pure india-rubber, then two layers of vulcanised india-rubber bound round with two layers of india-rubber strip, then a layer of jute, the whole being sheathed with iron wires, No. 9 B.W.G., and covered with a final covering of jute soaked in bitumen. The cables are simply buried, no conduits being used, on account of the low-lying level of the ground and its extreme humidity. After a year's running an insulation test was made which gave very satisfactory results. The transformers are usually placed as near as possible the entrance of the primary leads into the houses so as to minimise the risk consequent on having any long lengths of wire under high pressure in the houses. One large transformer is sometimes used for several consumers when they are situated near together. The size of the transformer is so chosen that the number of lamps for which it is designed corresponds to the normal number of lights usually alight, and not the maximum number of lamps fitted. Before passing into the transformer the current passes through a two-pole switch and a

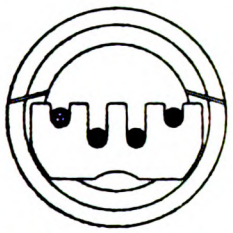

Fig. 1.—Boulogne Central Station. Stoneware Conduit.

fuse, and the secondary current on leaving the transformer passes through a cut-out, especially designed by the Company. The current finally traverses the meter, which is always situated in as dry a place as possible. The cost of the supply is about the lowest on the Continent, being 7·7d. per kilowatt hour.

At Boulogne-sur-Mer, on the other hand, the system adopted is very different. When the Société pour la Transmission de la Force undertook the electric lighting of the town, another large scheme was afloat, namely, the electric lighting of the railway station. The site selected for the railway station plant was naturally close by, and when it was subsequently decided to merge the two schemes into one, the railway station site was retained, although it involved the disadvantage of having the generating depôt on the wrong side of the river and a long way away from the part of the town where customers were to be anticipated. Hence the necessity for the adoption, if the three-wire method of distribution was to be adhered to, of the somewhat cumbersome system to be described.

The generating plant is on the left bank of the Lianne, three-quarters of a mile from the distributing centre on the Place Frédéric-Sauvage. Two horizontal condensing Weyher-Richemond engines of 125 H.P. each drive through belting two 350-volt, 250-ampere Desroziers dynamos employed to charge a battery of 138 storage cells placed at the distributing centre; a smaller machine supplying current to a battery feeding the lamps at the Gare du Nord. The line is overhead for the most part. The distributing net work consists partly of bare copper conductors in trenches, and partly of *insulated* cables laid in stoneware pipes and supported on glass saddle pieces (*see* Fig. 1). It is probably owing to these precautions that the use of these stoneware pipes has not in Boulogne given rise to the mishaps which have occurred in Paris. The central station has been at work for about a year with satisfactory results. Some 5,000 lamps are at present connected to the mains. The price of the hectowatt hour is 12 centimes, which is practically equivalent to the Board of Trade unit at a shilling. The price of Boulogne gas is about 7s. a thousand. Brillié meters are almost exclusively employed.

The switchboard at the distributing centre contains, besides the usual hand devices for switching cells in and out of circuit as circumstances may require, an arrangement shown in Fig. 2 for interchanging the position of the two halves of the battery, with regard to the neutral wire. This interchange is carried out every day at noon, with a view to preventing unequal charge and discharge of the two sets of cells. On the board are arranged four series of jaws, the two on the right belonging to one half of the battery, and the other two to the other half. Two sets of contact pieces revolve on two spindles situated between the rows of clips. By means of a worm and two

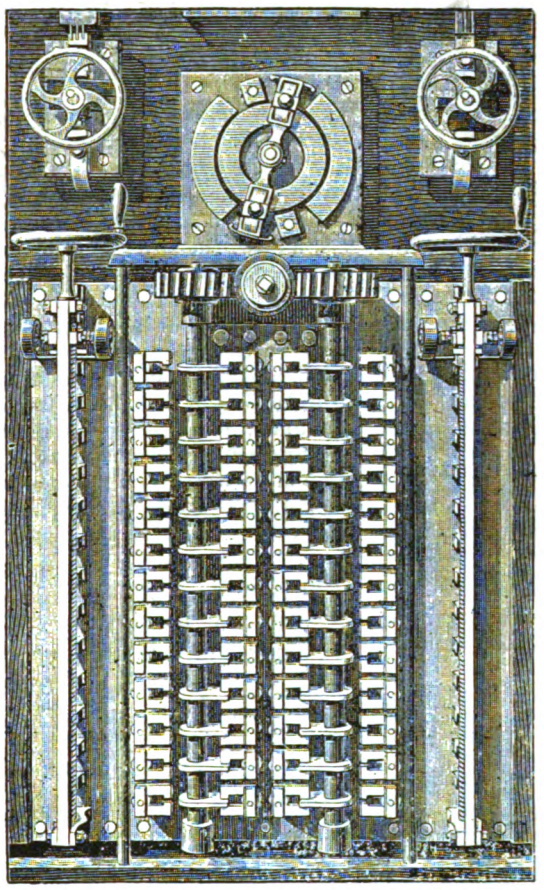

Fig. 2.—Boulogne Central Station. Switchboard for Transposing the Two Halves of a Storage Battery connected to a Three-wire Circuit.

toothed wheels, as shown, both the spindles are rotated at the same time, and the two halves of the battery interchanged. The whole operation is stated by *La Lumière Electrique*, to whom we are indebted for some of these particulars and for the illustrations, to take "hardly two or three minutes, and to cause no trouble to the supply."

Kensington Vestry.—At a recent meeting of this Vestry Mr. F. L. Chandler moved, "That inasmuch as complaints are being made by residents in the district of North Kensington, included in the area allotted to the House-to-House Electric Lighting Company of their failure in not supplying electricity, it be referred to the Works and Sanitary Committee to consider the best steps to be taken to compel the Company to carry out the provisions of their Order in regard to the laying of distributing mains in the district referred to." This was agreed to.

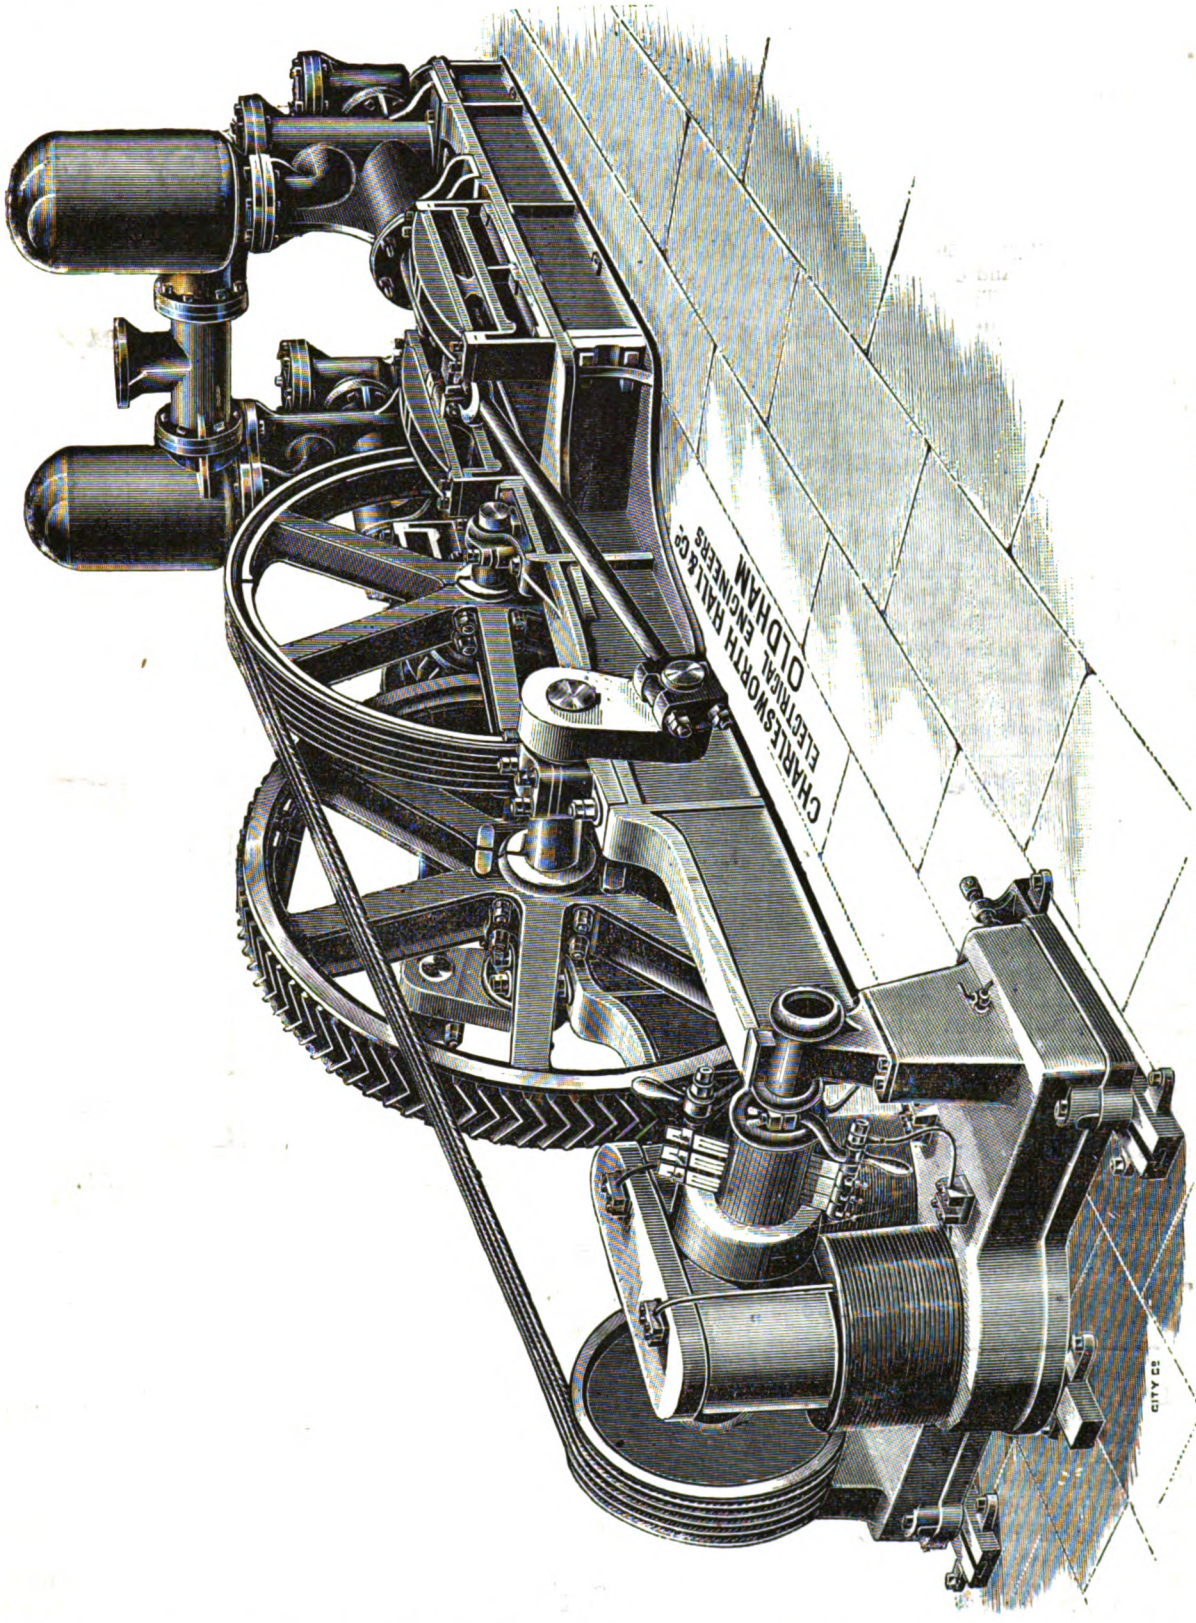
ELECTRIC PUMPING PLANT.

This plant, constructed by Messrs. Charlesworth, Hall and Co., for Messrs. Platt Brothers and Co. (Limited), for Jubilee Colliery, Shaw, was installed in November, 1890, and has since then been running continuously from 100 to 150 hours per week, except for four or five hours on a few occasions through the fuses, &c., burning out through various causes. It consists of a steam engine on the surface, working a dynamo which supplies current to a motor below fixed in one of the roads about 750 yards from the bottom of the shaft, at a depth of 120 yds. This drives a pump delivering its water into the sump, and from thence is raised to the surface by the main steam pumps placed at the bottom of the shaft.

The steam engine is an old single cylinder condensing, much too large to work economically with the dynamo only. The following are the particulars as taken during a test on 23rd January, 1891 :—



Electric Pump by Charlesworth, Hall and Co. Capacity, 577 gallons per hour, raised 142 feet.

The cylinder is 28in. in diameter, and has a 42in. stroke running at 54 revolutions per minute, and driving from a 15ft. flywheel rope pulley on to a 4ft. pulley on a countershaft with six 1½in. ropes, and a 6ft. pulley on the countershaft drives a

Digitized by Google

2ft. 6in. on the dynamo by six 1¼in. ropes. The engine indicates 21·58 with the brushes off the dynamo, and 62 H.P. with ordinary load, which is equal to about 36 per cent. of the full load power given out by the engine.

The dynamo is an "Oldham" series-wound machine, giving a current of 48·5 amperes at 580 volts = 28,230 watts, or 37·7 E.H.P. at 490 revolutions per minute when absorbing 40·1 I.H.P.

The cables are 37/17s lead covered, and are carried down the shaft and at the bottom in strong wood casing to protect them from mechanical injury, and are laid in a trench along the road below the surface, and at the side of the rails. Their resistance is 0·334 ohm, which at ordinary load as above = 1·05 H.P. loss.

The motor is in all respects similar to the dynamo, and, when taking 48·5 amperes at 567 volts, runs at 406 revolutions per minute, and gives out 35·53 H.P. It drives the pump with six 1¼in. ropes from a 36in. pulley on to one 7ft. diameter on pump. On this shaft is a double-shrouded helical steel pinion, with 18 teeth, gearing into a wheel having 90 teeth on the crank-shaft, which has two cranks of 15in. throw; the rams of the pump are 9in. diameter, and ran during the test at 35 revolutions per minute, indicating 24·3 H.P. on the water cylinders, and delivered 577 gallons per minute, against 142ft. vertical head. The engine-room is provided with both volt and ammeter in a convenient position in view of the engineer when starting, the pump-house also is provided with an ammeter, so that the man in charge of the pump can see that all is working easily.

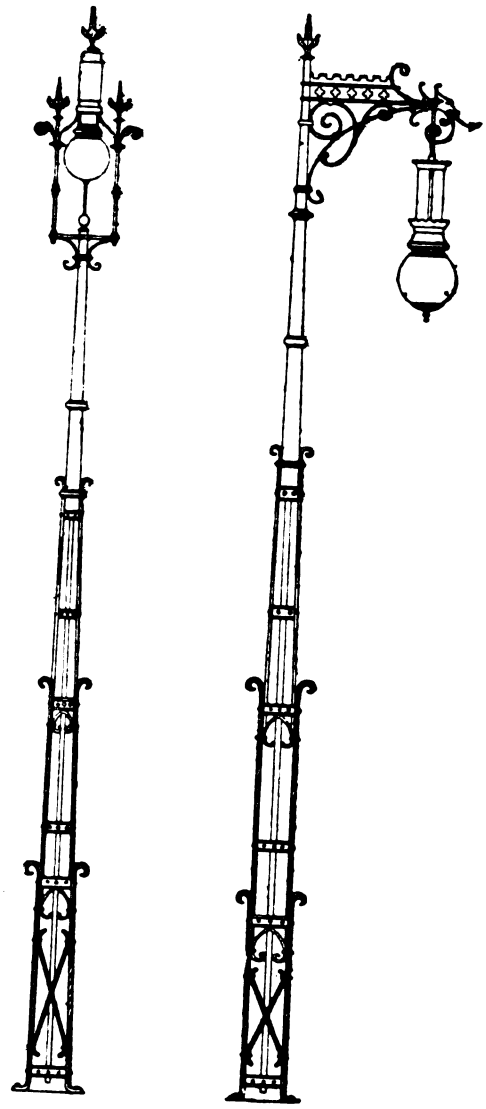
Main high-tension water-break fuses are fitted on both mains in the engine-room in close proximity to the dynamo. The engine-house on the surface, and the pump-house below, are connected with a signal-bell. The pump-house is lighted with incandescent lights off the main circuit. The following table gives the results of a test made in January, 1891, in which all the various sources of loss were tested separately, and are as accurate as colliery conditions permit:—

Power given in.	Engine gives 62 I.H.P., which is accounted for as below. I.H.P.	I.H.P. of engine, accounted for as below. Per cent.	Actual H.P. received by dynamo, accounted for as below. Per cent.
Power lost between engine and dynamo with full load	21·90	35·31	—
Power lost in dynamo	2·26	3·65	5·67
Power lost in cables	1·05	1·69	2·62
Power lost in motor	2·26	3·65	5·64
Power lost in pumps and gearing when working at full speed..	10·23	16·51	25·50
Power lost by friction of water in pumps and pipes.....	4·58	7·39	11·40
Calculated power represented from the *actual water raised* by the pumps allowing nothing for friction or losses.	19·72	31·80	49·20
	62·00	100·00	100·00

Power used by dynamo available at motor = 86·1 per cent.
Losses in dynamo, cables, and motor = 13·9 "
100·0 "

LAMP POSTS FOR OXFORD.

The arc-light posts which now adorn all the main thoroughfares of the City are in their way an interesting instance of progressive development from the distinctly ugly to the passably ornamental. The first half-dozen eyesores, with their peg-like excrescences, were heavy to an extreme; then followed a lighter type of post with some pretensions to the artistic, and within the last week or so a still more ornamental type has appeared upon the scene. "Made in Germany" is generally a synonym for "mediocrity," and often for "cheap and nasty," but this applies more to small and sundry goods than to important engineering construction. "Designed in Germany," on the other hand, conveys a very different idea, though why this should be the case, when Art Schools are scattered up and down the country, it is difficult to see. The Oxford Electric Light Company have had to go all the way to Munich in order to obtain patterns for lamp posts in keeping with Oxford architecture. In good time, no doubt, an entirely new species of post will be evolved, having a less pronounced likeness to a magnified gas lamp than is the case with the arc-light supports which at present form a marked addition to the numerous obstructions that impede pedestrian traffic along the narrow pavements of



Lamp Posts for Oxford, Designed at Munich.

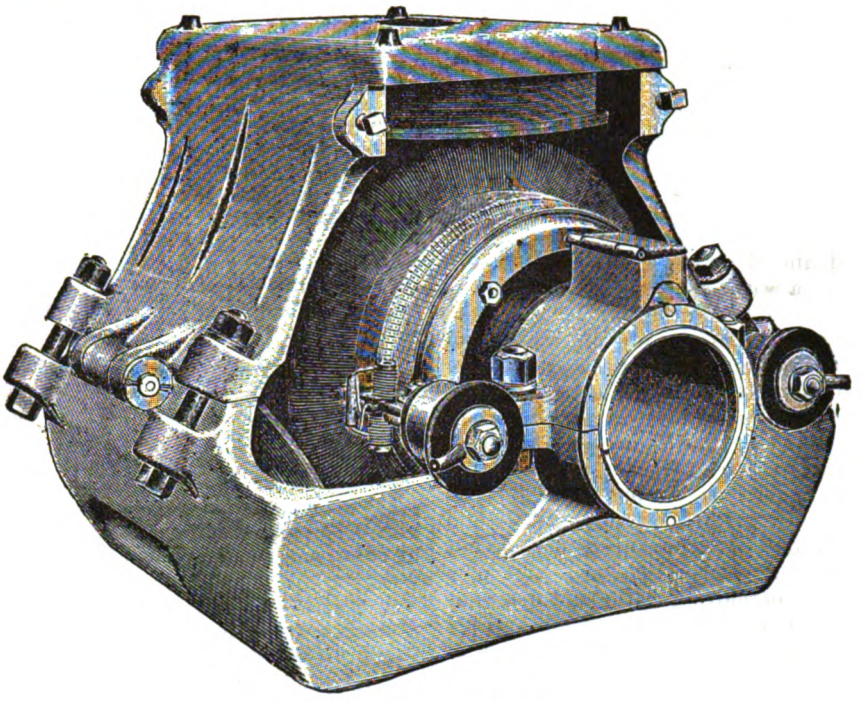
Fleet-street and Cheapside. These Oxford lamp posts seem to be a great advance on anything that has yet been erected in this country. The extreme height of each pattern is 25 feet.

THE NEW SHORT GEARLESS MOTOR.

One of the most interesting exhibits at the National Street Railway Convention at Cleveland, O., will, says the *Electrical World*, undoubtedly be the new gearless motor which Prof. Short has recently designed. The Short Company has undertaken the development and perfection of this machine. The first type of this motor was exhibited a year ago at Pittsburgh (see *The Electrician*, Vol. XXVI., p. 708). This motor, a four-pole machine, had an armature 24in. in diameter. The armature was of the Paccinotti type, with the field magnets, eight in number, presented on either side, and the whole encased in a cast-iron frame, and provided with a hollow shaft through which the axle of the car played freely in a flexible driving

Digitized by Google

clutch. The car at the convention was provided with two of these motors, each having a capacity of 20 H.P. It was necessary to mount these motors on 36in. wheels owing to the size of the armature ring. A number of these motors were manufactured and shipped to various places, and they have now been in operation about a year, with a nominal cost of repairs. This motor, however, was not satisfactory to the Short Company, owing to its size and weight, and the cost of manufacture. A second design embodying the same principles but arranged so that the field magnets were presented to the face of the armature ring has been brought out within the year, and a number manufactured and sold. These motors were adapted to 33in. wheels, and the efficiency of the machine was increased. These machines weighed 3,000lb. Within the last three months, however, the Short Company has placed upon the market an entirely new type of gearless motor arranged for 30in. wheels, and weighing only 2,300lb., which they believe will fulfill the requirements of street railway practice, except where exceedingly low speed is required. This motor (*see* figure) is triangular in shape, and has three field magnet cores cast integrally with the frame and three consequent pole pieces, making a six-pole machine of a peculiar form. The frame is cast of the softest steel. The armature is ironclad, the wire being sunk into the metal so that it is protected magnetically. The commutator is large, and has an ample carrying capacity. Only two carbon brushes are used. The machine is entirely waterproof, and the copper on both armature and field magnets has large carrying capacity. An efficiency is claimed of nearly 90 per cent. at one part of its load, and over 75 per cent. at full load. When placed in series two of these motors will make about 10 miles an hour, with ordinary loads on level track, while in parallel they will make about 20 miles an hour. At full load these motors are designed to make 12 miles an hour when placed in parallel. The machine now ready for the market has a capacity of from 20 H.P. to 25 H.P., but motors of larger size are being designed especially with reference to suburban traffic on interurban lines where high speed is to be attained, and trains of cars are to be pulled.



The Short Gearless Motor.

A REGULATING SWITCH.

In connection with our recent remarks on switches for regulating glow lamps, the General Electric Company have sent us a resistance switch for this purpose. Knowing that not much economy could be effected, we have made inquiries about the purposes for which such switches are demanded, and we are informed by the General Electric Company that they are specially appreciated in sick rooms, where a dim light is required all night. We have made a rough test with this switch, and find that on a 100-volt circuit, the handle being moved over, as shown in the illustration, practically no resistance is interposed. On the second point the light is reduced to about one quarter, and on the third point to about one-eighth. The light yielded by the lamps when the handle is on the other points is hardly perceptible. Taking the cost of an eight-candle lamp burning for 32 hours as 8d., the cost for the same period with the handle on the second point would be about 7d., and on the third point 5½d, as against 4d. and 1d., which would obtain if the cost of the light were reduced proportionately to its amount.

In sick rooms the convenience of such an arrangement is not to be measured by the cost. With alternating currents a very slightly better result could be obtained by the use of a choking coil, as far as the watts consumed are concerned; but the whole of this saving would not be recorded on the meter, as meters are at present constructed. It should be remembered that although a gas-burner is turned down with ease, a similar reduction of efficiency takes place. Some interesting figures on the cost of gas-lighting were given by Prof. Ayrton at the Royal Institution last session; but, as far as we are aware, they have never been published. This resistance switch will carry 1½ amperes, and contains 300 ohms. The resistance is imbedded in a new patent insulator, which is expected to present several advantages over enamelled resistances.

TRADE CATALOGUES.

When is a catalogue not a catalogue? The first answer to this question might be—when it contains no prices. But several catalogues consist, as far as they are printed, in mere lists of goods, the prices of any particular articles inquired for being filled in by hand. Others, such as the one issued recently by Messrs. J. E. H. Gordon and Co., contain only elaborate descriptions of executed contracts. A continental custom is to produce a book looking like a regular scientific treatise, but really a collection of illustrated descriptions of various instruments and machines. Provided that the work contains plenty of information we do not think that its dignity need be lowered by the addition of a few prices, but in some cases it is almost impossible to give any figures, and this especially where very large plant is dealt with. As a very remarkable specimen of a catalogue which, with one or two insignificant exceptions on the last pages, is entirely free from prices, we may mention the admirably-printed handbook of Messrs. John Musgrave and Son, of Bolton. This is devoted to high-class mill engines, and by way of assisting purchasers in making a choice of an engine suited to the work to be done, and the conditions under which it is to be used, a most useful and interesting introduction is provided, in which the use of valve-gear, the effect of clearances, drainage, steam jackets, and the proportions of cylinders are discussed. By the aid of indicator diagrams and fully worked out examples, the question, "Why are compound and triple expansion engines more economical than single cylinder (or simple engines)?" is answered. In the 16 pages devoted to this problem, we find large scale diagrams of not only from steam indicators, but graphic crank-pressure diagrams, plotted on each side of a correctly-drawn line of inertia of moving parts, and diagrams of the resultant turning moments. These diagrams have been worked out for both simple and compound engines, and are of an altogether different character from the blackboard sketches, which too often appear in text-books. Fully illustrated descriptions of important steam engines are given, together with indicator diagrams and numerous details of dimensions, a very large number of types being described. Many of the illustrations are very fine specimens of wood engraving. A number of examples of rope driving, and sectional and plan diagrams of mills, showing the distribution of power by this method, are given, together with dimensions of drums and of ropes, with their speed and the power transmitted by each. The latter part of the volume contains sections on the design and proportions of pulleys and drums, for ropes and belts, friction clutches, toothed gearing, belt driving, shafting, and 36 pages are occupied with boilers and tables of coal consumption. We wish that this book could have a wider circulation than seems to be intended. On the cover we find "With the compliments of John Musgrave and Sons (Limited)," and on the back of the title-page we read, "Price one guinea." Under these circumstances it is hardly likely to get into the hands of students and young engineers, who might get much valuable information from its pages.

Of an intermediate kind is a catalogue of Mr. Schall, which, though it contains a price list, gives an excellent account of the apparatus used for medical and surgical purposes, together with many practical hints, and an introduction giving a sketch of Ohm's law, units, &c. Very clear directions are given for connecting cells to produce different effects, with examples of the arrangement of batteries for cautery, showing the important effect of internal resistance which so often puzzles a beginner. The price list is well illustrated, and contains a great variety of apparatus.

We have been favoured with a preliminary inspection of some advance sheets of the new catalogue of the General Electric Company, of Queen Victoria-street. This, though altogether surpassing the previous catalogues of this firm, will be essentially a price list; but interspersed among the 500 pages there are many useful hints, and in some cases careful instructions on the use of the articles described. The following is an abstract of the introduction to the section on switches:—

A switch is an appliance for conveniently making or breaking an electrical circuit. We divide our switches into two classes, main switches and branch switches. The main switches are for 20 amperes and upwards, and the branch switches for circuits of smaller capacity. These switches are again divided into two classes, single pole, which break circuit on one wire only, and double pole, which make or break the contact simultaneously on both wires. Each of the above-mentioned switches is made in great variety, and for serving a number of purposes. The main switches, for instance, can be subdivided into single contact switches and multiple contact switches, the latter being used for ammeter switch, for regulating two or more circuits, and for regulating resistances or accumulator circuits. The branch switches are usually made single or double contact, with or without cut-out, as may be required, and are placed in a convenient place on the wall for controlling the various branches of the circuits. In a great many instances, however, these switches serve a special purpose, and are fixed accordingly; for instance, to a bracket (bracket switch), to a holder (switch holder), to a door (door switch) hanging from the ceiling by means of a flexible cord like a push (pear switch or pull switch). As may be judged by the great variety of switches, they form a very important part of an electric light installation, and in installations where the current is supplied from central stations, the switches are really the most important part, as they are constantly in use and almost the only appliance which is subject to direct handling on the part of the consumer. Of course, one type of switch cannot satisfy every requirement. In all of them, however, the following points have been considered:—

1. *Contact.*—Whether wedge contacts, fork contacts, or impact contact, they all should be good rubbing contacts, having large surface area compared with carrying capacity. The contact of the switch must be fully "on" or fully "off," no intermediate position must be possible.

2. *Springs.*—Owing to the necessity of a quick make or break, every switch must have some kind of a spring action. The simplest kind of spring is the most preferable. It is not so liable to get out of order, and no spring should be in tension when in the "off" position.

3. *Terminals.*—Proper terminals for easy wiring and making good contacts are most important. Those with set screws requiring no twisting of wires are the best.

4. *Handle.*—The most usual action for moving a switch is made by a turning or locking motion. The handle should be well insulated from the contacts and should be loose, that is the "off" position should be obtained independently of the handle.

5. *Bases.*—The use of china, the best insulator, has now been adopted for all our switch bases. All the metal parts are attached from the front, so that no conducting metal parts are visible at the back, and leakage through the walls is made impossible. The fixing and leading holes should be large to admit of high insulation wires.

We have no intention of criticising either the switches or the foregoing description, but take this opportunity of pointing out that in many switches, while no intermediate position is possible when turning "off," an inquisitive person can make an arc in turning "on." Some forms of impact switch get over this difficulty, but we observe that the General Electric Company introduce their pattern "to effectually meet foreign competition for a cheap switch." In saying that every switch must have some kind of spring action, large main switches may be excepted. So stiff must the contacts be, that when the switch is pulled open, it generally flies over fast enough against the stop. We are glad to find that the General Electric Company advocate set-screw terminals, and wish that these were more common than flat headed screws, with or without washers, for clamping wires. The fastening of metal parts to the front of china bases, so that no conducting metal parts are visible at the back, is an improvement which will, perhaps, some day be insisted upon by insurance inspectors.

Some useful hints are given in this catalogue about cut-outs, and explanations of their use are addressed to the uninitiated. Screw plugs and spring clips are condemned in the "general remarks on design of cut-outs," because "besides faulty contacts, the reliance on springs is always bad from an electrical point of view." This is rather a contradiction of the principles on which most switches are made, where wedge or spring contacts, between which it is difficult to discriminate, are in common use. A wedge or spring cut-out generally implies a more or less expensive fuse consisting of mica, fibre, or glass tube as a support for a wire or foil. When these are destroyed, a careless or ignorant person may replace them with a nail, or a domestic pin. The General Electric Company prefer a fuse

Digitized by Google

which must be fastened with a screw-driver. This they claim as an advantage, "as no good electrical contact is possible without a screw-driver being used, an instrument which can be handled by anybody, and now that electric lighting has become so popular, such an instrument will be as indispensable a household tool as a knife and fork." What a shocking confession! Did we believe it for a moment we should not give it publicity. We have all heard of the heroine who averted disaster at a brilliant ball by replacing the main fuse by a hair-pin; but what if a pocket screw-driver had been necessary! The fuses recommended consist of tin wire, thinly coated with shellac to prevent oxidation. These, known as the eclipse pattern, have copper clip ends, and are arranged so that a small fuse cannot possibly be inserted in a large cut out.

THE ELECTRICAL RESISTANCE OF METALS AND THE MEASUREMENT OF TEMPERATURE.*

BY C. E. GUILLAUME.

It is with good reason that we anticipate great things from the study of metals at very low temperatures. Lead, it seems, is very sonorous at −200°C., and in proportion as the temperature is lowered the number of magnetic metals and alloys increases. The investigation of electrical resistance *promises* much. I emphasise the term designedly, although in the opinion of some electricians the recent work of Profs. Dewar and Fleming is the realisation of the most splendid promises. While recognising the great value of that research I am a little less optimistic. It is very interesting to have followed the resistance of a large number of pure metals down to −182°C. or −197°C. We know now that the resistance shows no peculiarity for 15 metals and alloys, and this ample harvest of results confirms the opinion that the best method of measuring low temperatures consists in determining the electrical resistance of metals exposed to these temperatures. Mr. Callendar had already shown the same thing in another direction by investigating the resistance of platinum up +1500°C. The platinum-resistance thermometer seems available over a range of 1,700deg. But it is precisely at the extreme temperatures of Profs. Dewar and Fleming's determinations that discussion begins. How is −200°C. practically defined? Assuming *à priori* that the hydrogen thermometer failed at a certain unknown point, Wroblewski, making use of a thermo-electric couple as control, declared it was inaccurate from −193°C., whilst I showed how another phenomenon, the electrical resistance of copper also investigated by Wroblewski, confirmed the indications of the hydrogen thermometer. Profs. Dewar and Fleming do not say how they measured their temperatures, but everything leads one to believe that they base them on Wroblewski's experiments (indications of the German silver-copper couple), that is to say by extrapolation of an arbitrary phenomenon. Now, it is highly probable that the temperature indicated by this latter as being −197°C. is in reality somewhat lower, which the experiments themselves appear to confirm. In fact the straight lines connecting the points obtained at −100°C. and −182°C. for gold and platinum leaves below it the point obtained at −197°C., which if carried on to the straight line would indicate for both a temperature approximating −200°C. The contrary indication of iron does not bring in any fresh argument because the line representing the resistance is very curved for this metal. In reality, so long as it is not proved by the theory of gases that the hydrogen thermometer is worthy of confidence below −200°C., the best means of measuring these temperatures will be the variation of the electrical resistance of some concordant metals, their variation being determined at *known* temperatures comprised between +300°C. and −150°C., a little more if possible, and extrapolated below. The first result of the experiments we are speaking of will be, therefore, to give us a thermometric scale, and not the function which connects resistance with temperature, for this latter variable is unknown.

Down to −197°C. we are nearly all agreed; but as I have remarked, it is below this that opinions differ. These will be settled the moment the resistance of half-a-dozen pure metals at the temperature of nitrogen boiling at low pressure has been determined. It is the value of this temperature which these experiments give us by extrapolation. It is highly probable that the values of M. Olzewski, which are about 10deg. lower than those of Wroblewski (−211°C. for 9mm. of mercury), will be confirmed.

The fundamental hypothesis of the research we are discussing has led the authors to commit a small error, of small importance indeed, but very apparent. The temperature of the mixture of carbonic snow and ether has been assumed to be −80°C. Now if we plot the points on squared paper, we find for all the metals that the observation at −80°C. is above the curve connecting +100°C., 0°C., and −100°C. Are we to conclude that there is an anomaly in the resistance? Evidently not. It is more logical to correct this temperature. Now this is what we get by interpolation —

Platinum	−71°C.	Tin	−74°C.
Gold	−74°C.	Bronze	−72°C.
Silver	−71°C.	Platinum, Iridium	−75°C.
Nickel	−75°C.	„ Rhodium	−70°C.

Mean −73°C.

It would therefore seem certain that the mixture in question produces a slightly variable temperature about −73°C. We shall do well for the moment to entirely disregard this point in our calculations.

The experiments of Profs. Dewar and Fleming are, as it is, very important. They will become more so and in a new direction, if the authors, so magnificently equipped, will go down another twenty degrees, unfortunately the most difficult to gain, or rather to lose.

* From *L'Industrie Electrique*, October 25th.

THE LOWEST TENDER.*

Not long since we stated that the last word remained to be said concerning the Baldwin engine contracts for New South Wales. Messrs. Neilsons' letter to the *Sydney Herald*, which, at the re-request of the firm, we publish this week, is an apt commentary on our expression of opinion. The letter possesses, however, an abstract practical interest quite apart from Sydney affairs. It directs attention once more to an old subject of discussion and contention, and raises a question which has never yet been satisfactorily settled, namely, the rights of the lowest tender. It is a matter of very great importance to engineers, and we venture to think that it may be reopened and written about with some advantage. The point at issue is, in a sense, extremely simple. Tenders are solicited for the performance of some particular work. The ruling idea is that, reversing the practice of ordinary auctions, whoever names the lowest price will secure the contract. In many cases, however, the lowest tender does not secure the contract. Of this complaint is made as a grievance; whether it is justly so regarded is, however, we think, a point which does not admit being disposed of in an off-hand fashion.

For the sake of illustration we may extend the auction simile, and regard a contract which several persons are anxious to secure in the light of an article sold to the highest bidder. In fact, it will be seen that the individuals or firms tendering are precisely in the same position as persons bidding at an auction. It is perfectly understood that unless a reserve price is put on an article it will be sold to the highest bidder. The question whether the reserve price shall be announced or not need scarcely be considered here; so long as it is made perfectly clear that the highest bidder will not necessarily secure the article for which he bids, no one can complain of being deceived or badly treated. In fact, under the 30th and 31st Vict., c. 48, the "conditions of sale" must say whether there is or is not a reserve. On the same general principle it is very frequently stated in advertisements, that the "lowest or any tender will not necessarily be accepted," and under that condition we do not think that any tenderer has legitimate cause for complaint if he finds that some other individual or firm has obtained a given contract at a higher price than that for which he had offered to do the work. Indeed, it is highly desirable in a very large class of contracts that the engineer should reserve to himself the power of declining to accept a given tender. It may, for example, be within his knowledge that the party tendering does not possess the requisite skill or capital to carry out the contract. All this is quite clear, and cannot legitimately be made the subject of discussion.

Trouble arises under a different set of conditions. Instead of tenders being asked for broadcast, a few firms of known reputation are selected. These and these alone are solicited to send in tenders. Nothing whatever is said as to what we may term a reserve price. Accordingly the tenders are sent in. Very frequently they involve in their preparation a great deal of trouble and expense. In the end the contract is awarded without any ostensible reason, not to the lowest tender, but to one possibly nearly, if not quite, the highest. There is here, at all events, an appearance of unfair dealing which is very unpleasant and most undesirable; and it is this that gives rise to strenuous assertions concerning the rights of the lowest tender. The numerous discussions which have taken place at various times all seem to rage round this one question—Has or has not the lowest tender any rights? On the one side it is urged that those who ask for tenders may with absolute propriety select whom they please to carry out their work, without regard to price; and that they are in no way bound to give any rea-

* From the *Engineer*.

Digitized by Google

sons why they should select B instead of A or D; and that, in point of fact, a statement of their reasons for declining the lowest tender might possibly involve them in actions for libel, or inflict considerable injury on a given firm. Thus, for example, we can call to mind a case which occurred some years ago, when tenders were asked for pipes of various sizes. Only certain selected firms were named. The lowest tender was not accepted, because it came from a firm which did not possess the plant necessary for making the largest pipes in the contract; and it was believed that the contract would, as regarded these pipes, be sublet. No reason, however, was assigned for passing over its tender. It was held to be unadvisable, for sufficient reasons, to go into explanations. The mistake made here, and the hardship involved, lay in calling on this particular firm to tender at all, as the facts concerning it were all known in advance. It forms no part of our purpose to deal with cases in which something closely akin to dishonesty is the principal factor in awarding a contract. We confine our attention to those legitimate cases which occur all too frequently, and in which wrong is done by what may, in a sense, be called sheer inadvertence. Half-a-dozen firms are asked for tenders, and no trace of an intimation is to be found in advertisements, correspondence, or interviews, that the lowest tender may not secure the contract. Under these circumstances we hold that wrong may be done to the lowest tenderer, no matter how innocently; and for this reason, among others, when a firm knows that it is one of a few specially selected—and such a fact cannot be kept secret—and believes that award of the contract is certain to be secured by the lowest tenderer, very great care will be taken to prepare the estimates in minute detail. Quantities will be taken out with precision. Prices will be got at as closely as possible. Estimating clerks, the foremen of departments, the chief draughtsman, the manager, the heads of the firm will all devote days and nights of labour, when a large contract is in view, to ascertaining what is the lowest sum at which it is worth while to undertake the work. In not a few cases other contracts are neglected. Orders are refused, or quoted for at prohibitory rates, in the reasonable expectation that the prices ascertained with so much labour will be low enough to secure the contract sought. The tender is sent in; and after all it is found that the order has gone to a rival whose prices are considerably higher. It is no matter for wonder if hard things are said under the circumstances. On the other hand, however, we cannot think that a lowest tender really possesses any rights whatever. It certainly has no legal rights fixed by Act of Parliament, such as are possessed by a purchaser at an auction, nor can it be said that "trade custom" gives a right; for, unfortunately, the lowest tender is frequently passed over in favour of one which is higher, without any ostensible reason.

There is, however, a far higher standpoint from which to regard the whole question—that of the honourable man. Nothing would be easier, we think, than to make it abundantly clear that the engineer reserves to himself the right, under all circumstances, to decline to accept the lowest tender. Then firms tendering will understand that although the price to be paid is a matter of importance, it is not the only matter of importance; and that other considerations may rule the mind of the engineer in advising his clients to accept any particular offer to the exclusion of all the rest. The difficulty is, of course, that when half-a-dozen firms are all equally eminent, all equally possessed of a world-wide reputation, none of them can see any other than a pecuniary reason for accepting the offer of one and excluding those of all the others. In a word, they argue that A, B and C would all do the work equally well if they got the chance, there is no reason other than the price at which they are willing to do it that should influence the engineer in making his choice among them. It is quite certain, however, that there may be and often are reasons, and that it is highly undesirable in any case that the engineer should have his hands tied; but it is none the less clear that he ought to be very careful to make all concerned understand that the contract will not necessarily go to the lowest tender. In one word, the stipulation that the engineer will not necessarily accept the lowest contract should be invariably, instead of exceptionally, put prominently forward. Even the suspicion of unfair dealing could scarcely exist under such a rule of action.

AN ELECTRIC LIGHTING IMBROGLIO.

The following facts relating to the electric lighting of a small town within a hundred miles of the Metropolis are, we think, worth placing on record, as being sufficiently typical of the results which are sure to attend the undertaking of electric lighting in districts where the chances of financial success are of a highly speculative order. The publication of the name of the town would in no way enhance the value of this object-lesson.

The project, now two years old, for lighting the town in question by electricity, so far from being yet realised, has arrived at a very curious *impasse*. And still more oddly, everyone concerned in the matter on either side seems to be at fault. During the year 1892 the local electric lighting company obtained a Provisional Order authorising their proposed undertaking; but, of course, subject to the usual conditions laid down by the Board of Trade. One of these (Clause 7) required the Company, within six months from the date of the Order and before exercising any of the powers granted, to satisfy the Board of Trade of their ability to fully and efficiently discharge the duties and obligations imposed upon them; while a later proviso (Clause 21) stipulated that within two years of the commencement of the Order, the Company must lay down suitable and sufficient distributing mains for the purposes of general supply throughout every street specified in the second schedule, and should thereafter maintain the same. Having advanced thus far, the Company appear to have stuck fast, for not until recently do they appear to have taken any steps to comply with the preliminary conditions of the Order. Three principal streets in the town were scheduled, and a few months ago, apparently quite ignoring the requirements of Clause 7, the Company informed the Board of Trade that they were prepared to carry out a part of the work (two of the three streets), and asking the Board not to express dissatisfaction at their being unable to carry out the work over the whole area. This rather singular communication was forwarded to the Town Council, who, after much warm debate, adopted a resolution to inform the Board of Trade that they had no objection to the Company laying down mains in the two streets, provided the Board were satisfied that the Company had sufficient capital to do the work and to provide for the continuance of the supply of electricity for a reasonable period; and, further, to advise that conditions be imposed compelling the Company to lay down distributing mains and supply electrical energy over the whole area of supply within a fixed time. This resolution having been carried out, great surprise was caused by a reply from the Board of Trade (dated October 12th), stating that the Company had not yet even complied with Clause 7 of the Order, requiring them to satisfy the Board that they would be able to carry out the whole work; and further stating that the Board had no power to extend the time limited by Clause 21 (two years) for laying down mains in the streets scheduled. The discovery that the undertakers had not fulfilled the first and most important condition was startling enough, but it further appeared that the contractors had notified the Board of Trade that they were then (Oct. 7th) actually laying down mains, their letter saying that "the present works are in the nature of a pioneering enterprise; but arrangements are in hand for an early extension throughout the whole of the compulsory streets," this, notwithstanding the non-compliance with Clause 7. There was already a mystery somewhere, and a special meeting of the Town Council was convened. Then a fresh complication arose, for the Town Surveyor stated that *no* mains had been laid. The "undertakers'" letter was clear on this point, for it said, "The enclosed map shows the streets in which we are now laying mains as a commencement." It also described the system adopted, and stated that the whole of the machinery was in an advanced state of manufacture, and they expected to start lighting in the first week in December. A member of the Council (presumably a shareholder in the Company) said the contractors when they wrote that letter believed that by the time they received a reply the mains would be laid; but obviously if Section 7 had not been complied with the Company had no right to do any of the work. Moreover, although they had notified the Town Council of their intention to lay down mains, the time had not then expired within which the Council might give approval, viz., a month, and by proceeding with the work before hearing from the Council they would have rendered themselves liable to penalties; but as no mains had been laid that point lapsed. It was necessary, however, that the Town Council should deal with the Company's notice, and upon this a long and somewhat heated discussion arose. On the one hand it was urged that as the two years' limit for works had expired, and the Company had not even fulfilled the first condition of satisfying the Board of Trade as to their position, the Board should be asked to revoke the Provisional Order, and that the Corporation should take it over themselves and undertake the lighting. Then a plea was put in on behalf of the Company in consideration of the expense they had incurred, and the arrangements they had actually made; but over all hung the *crux*, which would seem to be logically and legally fatal, that the Company had forfeited their Order by their own remissness in regard to Clause 7. Furthermore, the Board of Trade had denied the possession of any power to extend the time-limit for works, and that introduced another limit of perplexity, for if the undertakers had failed to satisfy the Board within six months as to their ability to execute the Order, it is not easy to see how the question of extending the period for laying down the mains was to be solved. At any rate, the problem was too much for the Town Council, and they eventually arrived at a curious compromise by passing a resolution

Digitized by Google

expressing regret "that the Company have not satisfied the Board of Trade that they are in a position to fully and efficiently discharge the duties and obligations of the Provisional Order," and at the same time notifying the Company that they disapprove of the Company opening up any of the streets or "commencing any other works" until they have complied with the 7th Section of the Order. The scheme is thus again at a dead-lock, for the Company have not satisfied the Board of Trade, the Board of Trade cannot (as stated) extend the time, and the Corporation will neither let the Company proceed with the work nor undertake it themselves. An impartial Committee has been appointed to confer with the Company, and it will be interesting to see the next development of this complex puzzle.

THE ELECTRICAL TRADES' SECTION.

The Electrical Trades' Section of the London Chamber of Commerce met at Botolph House, Eastcheap, on Friday last, to consider various questions in connection with the electrical industry. Major Flood-Page occupied the chair.

The SECRETARY (Mr. Kenric B. Murray) having read the notice calling the meeting,

The CHAIRMAN said, with regard to the forthcoming Exhibition at Chicago, that the members of the Section had been circularised with the view of ascertaining whether they intended to send exhibits to the World's Fair, and as no answers had been received it might be taken for granted that the electrical industry, so far as it was represented by this Section, did not feel it possible to do so. He quite endorsed Mr. Binswanger's opinion, that, if they did exhibit at all, they ought to be worthily represented. Under these circumstances, the members would understand that they would take no further step in the matter.

The SECRETARY then read the correspondence which had taken place between the Chamber and the National Telephone Company, the County Council, and the New Telephone Company, on the subject of getting the Board of Trade Bye-Laws in respect to overhead wires altered, and thanking the Chamber for what they had done.

The CHAIRMAN said that there was a pressing matter added to the agenda since Mr. Edmunds had given notice of the subjects he intended to bring forward; and as Mr. Crompton had come to the meeting specially to give some information upon it, he would ask that gentleman to address them.

Mr. R. E. CROMPTON said that it was well within the knowledge of the members that this Section had been corresponding with the Board of Trade on the subject of overhead wires with a view to getting two of its rules modified, one as to the thickness of an insulation, and the other as to the means of suspending the wires. Their representations so far had not met with success. No modification in those rules had been allowed, and they had been told, that, until the whole matter was brought before the Board of Trade, and pressure put upon that body by some authority equal in scientific weight to the authority that formulated these rules in the first instance—the Council of the Institution of Electrical Engineers—the Board of Trade did not propose to make any change in them whatever. Acting on this decision, he had gone to the Council of the Institution of Electrical Engineers and pointed out that they were doing a gross injustice to the trade in not investigating this matter. Prof. Ayrton took the matter up, and a Committee was appointed, the first sitting of which took place the previous day. He might say that there was every disposition shown, not only to examine the operation of the two rules referred to, which pressed most heavily on the electrical industry, but also to consider the whole of the regulations promulgated by the Board of Trade in reference to electrical matters, and make an official inquiry into the subject. Beyond this he could not go, as, being a member of that Committee, he naturally could not divulge what took place at its deliberations. It had been abundantly clear to him, and he thought, to everyone who had been considering this question, that they must put the whole investigation on a wider basis than they had at first intended. They must not confine it to those two rules; but the general question of how far the Board of Trade should interfere with private electrical enterprise should be very carefully considered, and after such consideration, if they found that they really had their hands tied and the progress of their industry fettered by over-regulation, they should make a stern protest against it. He thought that but for this there was every sign that the interference complained of would continue to increase in the future. His own view was that the Board of Trade had no right to interfere in the matter of electrical supply, except in so far as the safety and protection of the public interest were concerned, in respect of accounts and questions of that kind. There was never any intention on the part of Parliament that that body should have power to regulate in detail their operations by specifying what sort of conductors should be used, and other such matters. His own and one or two other firms had suffered by this over-regulation, and it was quite certain that their loss had deterred other people from following their example, and, consequently, had prevented many towns from being lighted by overhead wires. The whole subject of the Board of Trade regulations, not only with respect to overhead wires, but with respect to general electrical supply, was one that ought to be looked into most carefully by the Chamber. They could not do justice to it unless they took it in hand promptly, and appointed a small Committee, with an energetic secretary to watch the action of that Department, as well as that of the Institution of Electrical Engineers, in regard to electrical matters.

Mr. E. GARCKE said that it was an exceedingly difficult question to find a satisfactory solution to. He quite agreed with Mr. Crompton that it was a very serious matter to their industry that it had been subjected to such unusual interference and regulations. He thought it spoke volumes for its inherent strength that it had developed so rapidly in spite of that interference, and he was quite of the opinion that they should do everything in their power to minimise such a baneful influence. He did not know if it would meet Mr. Crompton's views to simply appoint a Committee for the purpose of advising the Chamber on any matters in which they were interested, and which the Board of Trade was dealing with. For the present he would like to reserve his approval of the appointment of a Committee with independent powers. If the suggestion were confined to the appointment of a Sub-Committee of this Section, for the purpose of taking the whole question into consideration, and advising as to what course should be adopted, then he was heartily with Mr. Crompton.

The CHAIRMAN said that there could be no doubt in the mind of anybody connected with electricity that this was a very important question, and it was not fair that the burden of its solution should fall entirely on Mr. Crompton's shoulders. He had had, on the previous day, a conversation with Mr. Crompton on the subject, and he would suggest that the question brought before them divided itself into two—the one having reference to the Institution of Electrical Engineers, and the other to the Board of Trade. It seemed to him that if the latter, when issuing its rules, consulted, for its guidance, such a body as the former, it was the duty of this Section to get that Institution to alter their views. They should first endeavour to convince the Institution of Electrical Engineers that they were wrong in giving the advice under which the Board of Trade sheltered itself. If the Section could get them to modify their opinions, it could approach the Board of Trade with much greater chance of success.

Mr. BEAUMONT thought it was high time that the whole question raised should be thoroughly investigated.

The CHAIRMAN said they had two courses open to them. They could either go to the Institution of Electrical Engineers, and get them to act in unison with the Chamber, or they could take an independent course and ignore that Institution and say, as electrical traders, that they would go to the Board of Trade direct.

Mr. TROITER thought that it was most important that Mr. Crompton should receive a little more assistance than had been rendered. More practical support should be given to that gentleman.

Mr. CROMPTON said that it was a real weakness to their cause that it should be so closely identified with his name. It was known by the Board of Trade and the Institution of Electrical Engineers that he was financially connected with the Chelmsford business, and there might always be a suspicion that he was not talking disinterestedly. He formally moved, "That a Sub-Committee of the Section be appointed to consider the whole question of the regulation of the Board of Trade; to confer with the Institution of Electrical Engineers; to suggest a course of action; to collect information; to submit witnesses and report from time to time to the Section."

Mr. GARCKE seconded the resolution.

The CHAIRMAN said that the Committee should be so formed as to include those who would give the best possible assistance, and would cover the whole of the electrical industry.

Mr. SWINBURNE thought that it ought to be independent. If a Committee of the London Chamber of Commerce were going to say, "We should like to support you in getting the rules as to the overhead wires altered," the other Committee would be inclined to look upon them as treating the matter from a monetary point of view. This was not a financial question, it was one of science, and their Committee ought to take up that attitude.

Mr. TROTTER ventured to go so far as to say that it ought to be considered as a matter of trade, as distinct from science.

The resolution was agreed to, and the following gentlemen were appointed as the Committee:—Messrs. Raworth, Ferranti, Gray, Pott, Wharton, Garcke, Bayley, Erskine, Swinburne, Gordon, Parker, Crompton, and General Webber.

Mr. HENRY EDMUNDS then said that at the close of one of these meetings a few months ago Major Flood-Page asked if there were any suggestions with regard to the agenda which might be useful for the consideration of this Section. He told that gentleman that he thought there were several matters, among others the stan-

Digitized by Google

dardising of machinery, uniformity of prices, and foreign competition. With regard to the first, namely, the standardising of machinery, he had in his mind a difficulty that had been complained of by several manufacturers, the apparent thoughtlessness of consulting engineers in drawing up specifications, and making vexatious variations in detail, evidently more with the view of stamping their own individuality on the specification than considering the adaptation of the existing standard types of given makers to their requirements—for instance, in speeds and voltages of one portion of the machinery at the same time that common pressures, say, of 100 volts, were desired with relation to the outside circuit of distribution, all of which largely increased the cost of production, without any real good to the consumer, or increase in the efficiency of the plant; and he had no doubt if there could be collected from the several manufacturers in England to-day an accurate account of the distinct types of machines for the production of either alternating or direct currents ultimately to work at the same pressure as far as the lamps were concerned, they would be surprised to find the enormous number of types and variations in detail which might have been avoided, had it not been for the unnecessary variations in the specifications of different engineers. These variations had in every case lost to manufacturers considerable time in calculations and alterations of patterns and designs, and had been of no material good to the ultimate consumer. On the Continent and in America they found the practice very different from their own. The large manufacturing firms there having standard types of machines which every one knew and recognised, guaranteed to do a certain amount of work, under certain conditions, and which, in consequence, could be manufactured with much larger margins of profit, which, after all, was the point that they were all aiming at, than the multitudinous types which were found in this country. This matter did not end with the machinery, for they found the same variations in specifications for the installation of wires and cables, one engineer specifying one installation and another another, even where such cable had to be used under exactly the same conditions. It was these differences to which he wished to draw the attention of the Electrical Trades' Section of the Chamber of Commerce, as he considered that it would be well to encourage the recognition and use of standard types of electrical requisites in this country.

Mr. CROMPTON reminded them that it had been a great feather in the cap of this Section that it had done so much in connection with the screw business.

Mr. EDMUNDS said that with-regard to the second question, uniformity of prices, they stood on much more vexed and difficult ground; but the public were evidently bewildered when they saw the enormous disparity of prices tendered for the same work on the same specification, if any public or private building had to be lighted. The tenders in some cases varied several hundreds per cent., and the question had been very pertinently asked—Did electrical contractors to-day understand their business? Of course there was the contractor who imagined that the lowest tender would probably be accepted, and for the purposes of advertisement would often take work on terms which would involve considerable loss if properly carried out. But such a contractor felt that he paid for his advertisement in that way. Others would quote prohibitive prices, wishing to be in evidence, but not desiring to do that particular work. This might be taken as explanatory of the extremes of prices in the tenders for the same work. But was it not possible to encourage those who tendered a medium and fair price for the work? Of course they had no control over the decision of engineers in the acceptance of the lowest tender; but he thought that where a number of tenders for the same work varied very much on the same specification, it would often be evident that the lowest would be done at a loss, and he would ask whether something could not be done with regard to bringing about a common uniformity, or minimum of price, say, for an installation of lamps at per point, instead of the present wide range from 18s. to £2. The public were, unfortunately, as yet inexperienced in many cases as to the classes of work they get done for a given price, and were, therefore, apt to take the lowest offer, which merely encouraged bad work, slovenliness, loss, and general distrust all round. They found uniformity in other branches. The sixpenny telegram, the penny-a-mile Parliamentary train, the 3s. 9d. incandescent lamp, were all attended by beneficial results to those who did the work; and he would ask whether they were not able to bring a certain standard of work into practice, and get nearer to a uniformity of price for that standard, so that people might be discouraged from entering on work in which they would positively incur a loss?

Mr. GARCKE was afraid that a discussion on the point raised was not likely to lead to a practical conclusion. Mr. Edmunds was dealing with a question that could not be settled by the Chamber. They could not interfere with prices of work which was open to competition.

The CHAIRMAN thought it was not practicable to do anything in the way of bringing prices to a dead level. If they could give General Webber or Mr. Swinburne the control of the trade it might be done, but where they had a number of engineers to deal with it would be quite impossible.

Mr. EDMUNDS said that the next matter for consideration was the vexed one of foreign competition. It was the boast of most Englishmen that this was a free trade country, and, therefore, he felt great difficulty in introducing a question of this kind without wandering into abstract questions of Protection and other matters which had already been dealt with by men who had given years to the study of political economy; but, nevertheless, foreign competition was a very serious matter, especially with relation to goods which could not be protected by patent or design, and could not be labelled "made in Germany," or other foreign countries. The overflow goods produced by foreign makers were sold here at prices at which they would not be disposed of in their own countries, leaving little or no margin of profit, but merely enabling the foreigner to employ a larger number of hands and increase his turnover. This had a most serious effect on the profits of the English manufacturer, with a corresponding reduction in the wages of his workpeople. He admitted that it was difficult to suggest a remedy, but he found that many English buyers were beginning to be prejudiced against goods marked "made in Germany," or other places abroad, giving the preference to those manufactured here. This helped to meet the difficulty where the goods could be so marked; as, for instance, incandescent lamps which might shortly be met with stamped "made in Germany," in which case he had no doubt that the English made article would receive the preference; but when they came to goods which could not be so marked, as, for example, the manufactures that he was interested in, namely, wires and cables in their various forms, and so forth, where only the wrappers and labels could be made to indicate the place of origin, a greater difficulty presented itself. Therefore, would it be unfair to ask that as a protection to British industry all goods that could not be so marked, as to indicate to the consumer their place of origin, should have a duty imposed upon them, provided, of course, that they could be equally well manufactured here? Or could this Section indicate any other method of dealing with this matter?

The CHAIRMAN asked whether Mr. Edmunds could not devise a rule by which his wires could be identified as not of foreign make. It would be a good thing if they had a little of the patriotism that other countries had in excluding from their shores foreign manufactures.

General WEBBER said that it would be a very good idea, particularly in connection with the electrical industry, if the whole trade in England were to adopt a general trade mark, in addition to each particular firm's trade mark, so that all people would know that the article they were purchasing was manufactured in England. It would be an undoubted advantage to the industry in which they were all so much interested.

The proceedings then terminated.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 15, 1892.

Power Transmission Plants.—Some very interesting power transmission plants are now being designed or in process of construction in different parts of the country. One worth mentioning is that of Aspen, Colo., where the electric light station has for many years been remarkable, because of the extensive use made of water-power in the generation of electricity. The same company is now constructing a new plant which will furnish power for mining operations exclusively. Five Brush dynamos of 500 volts and 300 amperes each will be used; the transmission lines requiring 225,000 pounds of No. 0000 copper wire. The dynamos will be driven by five 57in. Pelton water-wheels under a head of 356ft., and developing 250 H.P. per wheel. The water is brought from separate streams by means of a 30in. pipe line, 4,000ft. long; a 24in. pipe line, 3,900ft. long; a wooden flume, 16,500ft. long; and another 12,000ft. long. Mr. C. E. Doolittle is the manager of the Company building this plant, and deserves the credit for most of the excellent work that has been done in this station since its establishment a number of years ago.

The Western Union Telegraph Company.—The Western Union Telegraph Company this week gave out a full tabulated statement of the earnings and expenditures, and other statistics of the Company for the year ending June 30th last, together with the same statistics for the corresponding

Digitized by Google

periods of 1891, 1890 and 1889. These figures show that the Company is operating 740,000 miles of wire by means of 20,700 offices, and that during the year over 62,000,000 messages were handled. The average receipts per message were 31·6 cents, while the average cost per message was 22·3 cents. The comparisons given herewith for the four years from 1889 to 1892 show a remarkable constancy in the average receipts per message, as well as for the average cost per message. The number of messages, however, has increased from 54,000,000 to 62,000,000 during the four years. The following table shows these comparisons :—

—	1892.	1891.	1890.	1889.
Gross	$23,706,404	$23,034,326	$22,387,028	$20,783,194
Operating expenses ...	16,307,857	16,428,741	15,074,303	14,565,152
Net	$7,398,547	$6,605,585	$7,312,725	$6,218,042
Interest and S. Fund...	930,523	931,219	915,135	835,655
Balance	$6,468,024	$5,674,365	$6,397,590	$5,382,386
Dividends	4,309,638	4,309,607	4,956,008	4,309,520
Surplus	$2,158,386	$1,364,758	$1,441,582	$1,072,866
Total surplus.....	$13,576,127	$11,417,741	$10,052,983	$8,611,401
Miles wire	739,106	715,591	678,997	643,697
Offices.....	20,700	20,098	19,382	18,710
Messages.....	62,387,298	59,148,343	55,878,762	54,108,326
Tolls per message	31·6	32·5	32·4	31·2
Cost per message	22·3	23·2	22·7	22·4

Large Dynamos.—It is reported on good authority that the General Electric Company is building at its Schenectady works some railway generators of the well-known Thomson-Houston multipolar type of 1,500 kilowatts capacity. It is presumed that these machines are intended to furnish current for the electric locomotives which that company is building for the Baltimore Belt Line tunnel and for other railway plants where large motors from 500 to 800 H.P. will be used. The Siemens and Halske Company has just placed on the market some 1,000 H.P. machines, and the Westinghouse Company has built some of a similar capacity for use in the World's Fair plant. The tendency with the companies seems to be towards the construction of large machines. The Westinghouse Company is building a 500 H.P. generator of a very curious type in the plant of the Narragansett Electric Lighting Company at Providence, R.I., taking a 500 H.P. compound slow-speed engine as the basis ; the designer has arranged the armature coils upon a frame which is fitted to the periphery of the engine fly-wheel ; the field coils are thus built up on a separate resting on the same foundation as the engine, this field coil frame being movable in a direction parallel with the engine shaft. Whatever may be the outcome of the test of an alternator built in this way, the design seems to be a decidedly crude one, and reminds one of the early attempts made in the construction of electric motors to make them as near as possible in appearance and operation correspond to the existing types of steam engine. This Westinghouse machine is side by side with a Thomson-Houston alternator of the same capacity but of different design, and an excellent opportunity will be afforded of testing the relative merits of the two machines.

Multiphase Transmission.—Multiphase transmission in America has, up to the present time, been a thing much talked about, but never put in practice. We are soon, however, to have a plant on a large scale transmitting power over a distance of 11½ miles, from the waterfalls in the Farmington river to Hartford, Conn. The machines are now being constructed by the General Electric Company, and the plant to be put in service at first will comprise a generator of 300 H.P. capacity, and a multiphase motor of the same size.

The "Columbus" Week Electrical Illuminations.—The past week has been almost a continuous holiday in New York City, the city being given up for the time being to the celebration of the Columbus quadri-centennial. It was anticipated that the electrical exhibits in the way of striking illuminations would be very fine ; but the general opinion, after having seen the attempts at display, was that the whole thing was a gigantic fizzle. A few meritorious designs were shown on the front of a few prominent buildings, notably that of the Edison Building, but the illumination of the "floats" in the procession was very much below what was expected.

The Edison Lamp Judgment.—The Edison lamp decision does not seem to have affected either the stocks of the companies interested or the business which they are doing. The Westinghouse people, however, claim that they have a new lamp, which they will put on the market on December 1st, which does not infringe the Edison fundamental patent, and for which they now announce that they are ready to take orders and make contracts. No official announcement has been made of what policy the General Electric Company will pursue in dealing with the smaller lamp companies, but probably the management is wise enough to foresee that it will be more advisable to compromise on the payment of a small royalty than to shut up the factories of these companies. At any rate, such seems to be the general impression.

A New Edison Company.—It has been announced that Mr. Edison, in connection with Mr. Henry Villard and other well-known financial men, has organised a new Company, and that he will withdraw from the General Electric Company, and give his attention to the interests of the new concern, which will make a special effort to extend its business in the North-western territory of the country, a field which Mr. Edison well knows is a very profitable one for the extension of electrical industries, both in the electric railway line and power applications for mining and other purposes. This report, however, has been vigorously denied, and it is not known definitely whether the rumour is well-founded or otherwise. At any rate a company has been formed at Minneapolis with a capitalisation of $12,000,000, in which a number of electrical men and financiers are interested.

CORRESPONDENCE.

A DISAVOWAL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : I see, with great regret, that my former colleague and *collaborateur* in various communications to the Institution of Electrical Engineers and other scientific societies, Dr. Arthur Harries, has issued a report in favour of the electropathic belts of Mr. Harness.

I must, therefore, ask you to be kind enough to allow me to make known, through your columns, that my connection with Dr. Harries ceased about 12 months ago.—Yours, &c.,

H. NEWMAN LAWRENCE, M.I.E.E.

THE PRINTING OF MATHEMATICAL SYMBOLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : With reference to the question of printing mathetical symbols, the solidus notation has not the disadvantage you suggest of being inapplicable when the numerator and denominator contain more than one term each, for the use of ordinary brackets prevents there being any ambiguity as to what fraction is meant : thus, $(A+B)/(C+D)$ is equivalent to $\frac{A+B}{C+D}$ and $A+B/C+D$ to $A+\frac{B}{C}+D$.

With regard to exponential expressions of the form $Aa^{f(x)}$, where $f(x)$ is any function of x, I suggest that the inverse notation $Alg_a^{-1}f(x) = Aa^{f(x)}$ offers a satisfactory solution of the difficulty, and that without the introduction of any new convention : thus the equation

$$i = \Sigma h e^{\frac{R(t-ckx}{ck^2+L}}$$

may be written

$$i = \Sigma hl g_e^{-1} \left\{ \frac{R(t-ckx)}{ck^2+L} \right\}$$

or

$$i = \Sigma h lg_e^{-1}\{R(t-ckx)/(ck^2+L)\}.$$

With regard to the notation for trigonometrical functions, I think it is a pity that it has come to be usual to write tan^2x

Digitized by Google

for $(tan\ x)^2$, *i.e.*, for the result of operating on $tan\ x$ with $tan\ x$: the meaning naturally applicable to $tan^2 x$ is $tan\ (tan\ x)$, and on operating once with tan^{-1} on $tan\ (tan\ x)$, we get $tan\ x$ and on operating again with tan^{-1} we get x. The inverse notation $tan^{-1} x$, which Prof. S. P. Thompson deprecates, is in consonance with the ideas of the calculus of operators, and a change to the Continental notation arc $tan\ x$ would, in this respect, be a retrograde step, I think.—Yours, &c.,

HAMILTON KILGOUR.

COST OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It may be of interest to record the result of a lengthy test to arrive at the prime cost of a Board of Trade unit of electricity when generated by means of a dynamo driven by a gas engine. The engine is a 12 H.P. nominal Otto (old type), the dynamo, a compound wound Siemens (1885 type) 160 volts, 40 amperes. The gas was measured by means of an ordinary dry meter and the electricity delivered to the cars on my Electric Railway by means of an Aron watt-meter carefully adjusted. The demand for current was of course variable, and had it been constant, the price per unit would have come out lower.

Cost of gas 2s. 9d. per 1,000 cubic feet, cost of electricity per unit 2·7 pence, add 0·1 for slide lights 2·8 pence, or 12·1 units for 1,000 c. f. gas.—Yours, &c., MAGNUS VOLK.

Brighton.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—EXTENSION OF TIME.—In *The Electrician* of August 26th, p. 469, a notification appeared that tenders for lighting the city of Belem do Gram Pará, Brazil, by gas or electricity would be received up to November 30th. This period has now been extended to December 30th. Particulars may be obtained from the Brazilian Legation or Consulate.

TENDERS ACCEPTED.—The tender of Messrs. G. Rennie and Co. has been accepted by the London County Council for a new steam ferry boat at the price of £17,500, or for £17,440 if the speed of the engine to be used for the electric lighting installation on board is to be 650 revolutions.

APPOINTMENT VACANT.—The Corporation of Oldham require an electrical engineer, experienced in the working of electrical plant, to supervise the laying of the mains, to take charge of the central station, &c. Particulars will be found in our advertising columns, and applications must be sent to Mr. A. Nicholson, town clerk, by November 2nd.

MESSRS. RUSSELL AND CO.—Under the style and title of Russell and Co., Earl Russell, who was until recently business manager for Messrs. Swinburne and Co., has commenced business at 11, Queen Victoria-street, E.C., as a general contracting electrical engineer. Little or no manufacturing business will be undertaken at present. Lord Russell has had considerable experience in electrical work.

EXTENSION OF PREMISES.—Mr. R. W. Paul, electrician and scientific instrument maker, has, owing to increasing business, been compelled to take additional premises in Leather-lane, Holborn, E.C. These new premises are situate near Mr. Paul's workshops and testing rooms in Hatton-garden, and have been fitted with steam-power and modern machine tools, &c.

EDISON GENERAL ELECTRIC COMPANY.—We have received from Mr. Philip S. Dyer a notice that on account of the recent consolidation between the Thomson-Houston International Electric Company and the Edison General Company of America (now called the General Electric Company of New York), the European business of the Company will be transferred from 34, Victoria-street, London, S.W., to 7, Rue du Louvre, Paris, where M. E. Thurnauer will represent the European interests of the Company, Mr. Dyer having given up his connection with the European agency.

REMOVAL NOTICE.—Messrs. North, North, and Co., until lately known as George North and Co., have, together with Mr. George North, removed from 90, Queen-street, E.C., to 61 and 62, Gracechurch-street, E.C.

HADWEN v. RICHARDSON (*In Chancery*).—Mr. T. W. Hadwen, the receiver in this matter, is now discharging the claims against the late firm of Messrs. A. W. Richardson and Co. Creditors will note.

THE EPSTEIN ELECTRIC ACCUMULATOR COMPANY (LIMITED).—We are asked to state that the offices of this Company have been removed from 34, Cannon-street to 19 and 21, Queen Victoria-street, E.C.

THE HEYL ACCUMULATOR.—It is stated that a large factory for the manufacture of the Heyl accumulator will shortly be established at Augsburg, Bavaria.

MESSRS. SIEMENS AND CO. (LIMITED).—An interesting article on Messrs. Siemens' and Co.'s Works at Woolwich appears in the *Belfast Evening Telegraph* of the 21st inst. This forms part of the series of articles on electric lighting which have appeared in that journal from time to time during the past month.

LIGHTING THE HOUSES OF PARLIAMENT.—In reference to a Note which appeared in our last issue respecting a special number of *Industries* dealing with the lighting, &c., of the Houses of Parliament, which was announced to be issued to-day (the 28th inst.), owing to some important alterations in the lighting arrangements which have recently been decided upon the issue of this special number is postponed till November 4th.

COUNTRY HOUSE LIGHTING.—Arisaig House, Arisaig, has recently been lighted by electricity, water power being utilised, and a saw mill being also driven by the turbine used for the lighting. The installation includes the farmhouses and stables adjoining. The contractor is Mr. Yorke, who has also completed the lighting at Inverie House, Oban.

VOLK'S ELECTRIC RAILWAY.—We have received a copy of the seventh edition of Volk's Electric Railway pamphlet, containing illustrations of the various points of interest on the line at Brighton, as well as particulars showing the cost of working, &c. The proportion of gross expenses to receipts (all repairs being paid out of revenue) represents 55 per cent. The figures given cover a period of eight years.

COMPAGNIE ELECTROMÉCANIQUE.—Ordinary and extraordinary meetings of this Company, which was formed in 1885 by Messrs. Weyher and Richemond, Menier, and Belleville, were held at Paris on Tuesday last to receive the accounts for the past year and to ratify the increase of capital caused by the inclusion of new firms. The Compagnie Continentale Edison and the Société Heilmann-Brown will take part in the Compagnie Electromécanique, the Edison Company transferring to the latter the construction of their dynamos, in order to devote their Ivry works entirely to the manufacture of electrical apparatus. It is stated that the Société Générale des Téléphones will have an interest in the Compagnie Electromécanique to the extent of 500,000 francs.

Re CHARLES JAMES ALLPORT.—This bankrupt, an electrical engineer, of Woburn-place, Russell-square, against whom a receiving order was made on May 26, 1891, has lodged with the Official Receiver a proposal for the settlement of his affairs. He proposes that a claim by the late Sir James Allport, amounting to £3,655, shall be withdrawn, and to pay 20s. in the pound upon the principal amount of the original debts due to his other creditors respectively, excluding any claim for interest. The debtor commenced business in 1882 with about £200 borrowed money. His liabilities, as shown by the statement of affairs, amounted to £14,880, with assets £43 only. The Official Receiver reports in favour of the proposal.

ELECTRIC PUMPING MACHINERY.—The Durban-Roodeport and Main Reef Companies have ordered electrical pumping machinery for their mining properties in South Africa.

PRINTING BY ELECTRICITY.—The *Bristol Times and Mirror* contains an interesting article from an American newspaper proprietor setting out the many advantages he has obtained by the introduction of electrical power for printing his journals. This installation was made on October 29, 1891, and has been a complete success.

"TEMPERED" COPPER.—We have received from Messrs. O. Berend and Co. a description of the product known as "tempered" copper, manufactured by the Eureka Tempered Copper Company, an American firm, which is now endeavouring to introduce this material for such purposes as commutators and trolley wheels, where a rubbing or rolling electrical connection has to be made. The metal is stated to be pure copper, without any alloying substance, and to owe the properties claimed for it to peculiarity of treatment rather than composition. Some months ago we caused inquiries to be made in America as to the precise nature of this treatment, but found that it was withheld as a "secret process," and no information was available. The analyses now put forward are not completely satisfactory, as they afford internal evidence of a want of precision, which impairs their value in judging the nature of a material of which nothing more definite is known. For example, it is unusual to find in a copper containing 99·981 per cent. of Cu. as much as 0·088 per cent., or nearly $\frac{1}{10}$th of a per cent., of iron, even if the fact that the whole analysis adds up to 100·154 per cent. be waived. When a degree of accuracy, represented by the use of the third

Digitized by Google

place of decimals, is attempted, it is somewhat anomalous to find an error in the total of 154 of the same units. The differences between the analyses of tempered and of untempered copper appear to us to be of the order of experimental errors. Be this as it may, there is evidence of the mechanical tests that "tempered" copper, in the form of wire and sheet, has a high tensile strength, and the experience of users points to the conclusion that castings of it wear well. What is wanted is a trustworthy report on the chemical and mechanical properties of "tempered" copper.

CLOUD ADVERTISING.—Experiments have been made at Earl's-court during this week to show the feasibility of advertising on the clouds by means of electricity, and from an æsthetic point of view, says the *Daily Telegraph*, have proved deplorably successful. Mr. Crompton, at whose Brompton works the demonstrations of this invention have been made, does not seem to hesitate to aid and abet Mr. E. Curtice, the inventor, in thus disfiguring the firmament. The only hope, says the *Globe*, is that if the practice of advertising in the heavens should become common, the rival advertisers will make such a hotch-potch of each other's announcements that they will all give it up in despair.

ELECTRICAL OMNIBUSES.—The first fruits of the offer made by the Electrical Power Storage Company to undertake the maintenance of batteries for traction purposes are to be found in a renewed promise from Mr. Radcliffe Ward to place his electric omnibuses for public service. "Probably in a fortnight the latest electrical omnibus will be running." We have heard this so often during the last three or four years, that we should continue to wait, were it not that the Electrical Power Storage Company have apparently accepted Mr. Ward's scheme, the practicability of which thus receives a very important endorsement. He seems to have got over to some extent the large non-paying load, but he makes a humorous excuse for the 3½ tons, as compared with 34cwt. for the heaviest horse 'bus, by saying that the electrical omnibus carries its horses on board. It is strange that the Hammersmith route should be adopted, a route on which competition has been most severe, and which comprises a stiff gradient in Piccadilly.

BRISTOL.—The report of the Electrical Committee has been presented to the Bristol Corporation, and its recommendation that the tender of Mr. Hayes for £13,346 for the erection of the central station has been adopted. In moving the acceptance of this tender, Mr. Pearson stated that Mr. Hayes's tender was £200 above the lowest, but he undertook to complete the work in nine months as against twelve months by the last tenderer, and this limitation of time would be strictly enforced. The Committee would shortly have to consider the question of distributing and transforming stations, and as soon as that work had been tendered for, the whole of the works in connection with the electric lighting station would have been arranged.

CAMBERWELL.—At the last meeting of the Camberwell Vestry it was resolved to empower the General Purposes Committee to secure the services of an electrical expert to deliver a lecture in the Lecture Hall, upon "How to Light Camberwell by Electricity."

CARDIFF.—At the last meeting of the Lighting and Electrical Committee of the Cardiff Corporation, plans for the proposed electric lighting works to be erected at the Great Western Railway, at Canton, were submitted on behalf of Mr. Massey, and were approved of by the Committee. Complaints against the dilatoriness of the Gas Company were heard, and it was urged upon the Committee by several of the members that steps should be taken to press forward the question of having the district lighted by electricity.

CHISWICK.—The Local Board have received a communication from the Board of Trade in reference to Messrs. Bourne and Grant's contract for electric lighting. The contractors have, we understand, raised the question as to whether the Local Board will have a transfer which will relieve them of all responsibility with regard to the supply of the electric light, or whether the firm are merely acting as contractors to the Board, the latter taking all responsibility. The matter has been referred to the Special Committee on Electric Lighting.

DUNDEE.—Messrs. A. M'Leod, of Dundee and Glasgow, have secured the contract for lighting the large premises of Messrs. W. Hunter and Co., drapers.

EALING.—The Electric Lighting Committee have adjourned until their next meeting the further consideration of the question of the electric lighting of the district, and in the meantime are obtaining particulars relative to the probable number of consumers likely to adopt the light.

GLASGOW.—The large warehouses of Messrs. Wyley and Rockhead in Buchanan-street have been fitted from basement to garret with the electric light, the installation consisting of 16, 32, 60, 160, and 300 c.p. lamps. On Monday last the light was critically tested for the matching of colours, carpets, wall papers, &c., and gave complete satisfaction. Messrs. Mavor and Coulson are the contractors for the work.

ILFORD.—At a recent meeting of the Ilford Ratepayers' Association it was proposed that electricity should be introduced into Ilford for lighting and other purposes, under the control and management of the Local Board. Mr. Thompson, who proposed the resolution, stated that Mr. H. J. Dowsing, of Messrs. Crompton and Co. (Limited), had offered to give a practical demonstration of the facilities of electricity for lighting and power, if arrangements were made for supplying the necessary motive power. It was resolved that a small Committee of the Ratepayers' Association should be formed to consider the matter, and that the Local Board should be asked to receive a deputation on the subject.

MOFFAT.—A meeting of the ratepayers of Moffat has been held to consider whether the Police Commissioners shall be advised to take steps to light the town by electricity. Mr. D. J. Brown, a Police Commissioner, showed the facilities which the district possessed for a water-power installation, and finally the motion that the electric light be adopted was carried.

NEWCASTLE.—Dissatisfaction is expressed by the tradesmen in Gray-street, an important thoroughfare of this town, owing to the present insufficient lighting, and a deputation lately waited upon the City Lighting Committee, urging the importance of better lighting, either by gas or electricity, a strong feeling being expressed that the electric light should be used. It was pointed out by the deputation that a considerable depreciation in the value of property in the neighbourhood of Gray-street had resulted from the insufficient lighting.

PETERBOROUGH.—Efforts are being made at Peterborough to induce the Cathedral authorities to substitute the electric light for gas in the Cathedral, which is now undergoing gradual restoration.

PRESCOT AND KNOWSLEY.—The British Insulated Wire Company (Limited) of Prescot have just completed the cable for the Prescot and Knowsley Hall installation. This installation includes the lighting of a number of factory premises in the district, amongst them being the Prescot Watch Factory, which has an installation of 1,500 lights.

SOUTHAMPTON.—At the last meeting of the Harbour Board the Works Committee reported the receipt of an application for the supply of electric power on the new pier for electric launches, &c. The formal contract with Messrs. Statter and Co. for electric cranes, &c., was assented to.

TYNESIDE.—The *Newcastle Journal* of Friday last contains interesting descriptions of Messrs. Parsons and Co.'s works at Watergate, and those of Messrs. Barnett and Co., in the same district.

WYCOMBE.—At the last meeting of the Corporation, Councillor Deacon called attention to the advantages which the Council would have by keeping the Electric Lighting Provisional Order in its own hands. He believed that in a few years the light would be used in every enlightened town in the country, as it was everywhere preferred to gas, both by private and public users. Councillor Baines, in supporting his colleague, remarked that the Council had made a mistake when they lost the gas works, and would make a still greater mistake if they lost the control of the electric lighting. The proposition to apply for a Provisional Order was carried by seven votes to two.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

October 1, 1892.

17,494. H. W. HORNE. Edinburgh. Electric indicator and apparatus for cooling any part of machinery which may become heated by friction.

17,504. D. LOCH. London. Improved operating electric switch.

17,509. T. R. ANDREWS and T. PREECE. Bradford. Improvements in the construction of field-magnets of dynamo electric generators.

17,526. L. KLERITJ. London. A magnetic water gauge or indicator of level liquid.

October 3, 1892.

17,563. W. R. WYNNE. Newcastle-on-Tyne. An improved detachable lamp jointing for removable lamps for shop fronts and similar situations.

17,605. F. HARRISON. London. A new or improved automatic electric switch.

Digitized by Google

October 4, 1892.

17,643. H. EDMUNDS. London. Improvements in electric switches.

17,647. H. HYLTON-FOSTER. London. Improvements in magneto-electric appliances.

17,653. A. J. LEHMAN. London. An improved process for treating cups, separating partitions or diaphragms, used in electric batteries or electrolytic apparatus.

17,691. L. HAVAUX. London. Apparatus for the cutting of glass by electricity.

October 5, 1892.

17,698. H. F. LEWIS and H. H. ELEY. Bristol. A new or improved polarised electrical indicator.

17,700. E. C. RUSSELL. London. An improvement in electric arc lamps.

17,717. H. J. AVERY and E. MORAND. Birmingham. Improvements in connection with electrical machines and coin-freed mechanism therefor.

17,718. H. ROSE. London. Improvements in, or relating to, electrical and mechanical telephone receivers.

17,743. E. DE PASS. London. Improvements in arc electric lamps. (L. Bardon, France.)

17,751. G. F. REDFERN. London. A door lock switch for electric lights. (C. Green, Canada.)

October 6, 1892.

17,774. E. W. COWAN and W. P. J. FAWCUS. Chester. Improvements in dynamo-electric machines and in their application to secondary battery installations.

17,826. M. HUTIN and M. LEBLANC. London. A method of transforming alternating electric currents of any tensions into continuous currents also of any tension, and conversely, and apparatus for that purpose.

17,855. T. TOMLINSON. London. Improvements in electrical distribution.

October 7, 1892.

17,877. T. R. ANDREWS and T. PREECE. Bradford. Improvements in regulators for dynamo-electric machines.

17,878. T. R. ANDREWS and T. PREECE. Bradford. Improvements in the method of, and apparatus for, starting electric motors.

17,895. F. E. ELMORE. London. Improvements in apparatus for the manufacture, electrolytically, of tubes and other articles of circular section.

17,909. C. E. CHALLIS. London. Electric switches.

17,922. F. KING and E. CLARK. London. Improvements in secondary batteries.

17,930. J. HIRSHFELD, W. MORRISON, A. P. MORRISON, and W. WRIGHT. New York (U.S.A.). Improvements in secondary batteries.

17,931. J. HIRSHFELD, W. MORRISON, A. P. MORRISON, and W. WRIGHT. New York (U.S.A.). An improvement in battery compounds.

October 8, 1892.

17,973. J. C. RICHARDSON. London. Improvements in electrolytic tanks.

17,974. P. MARINO. Surrey. Improvements in plating metallic surfaces and also prepared surfaces of non-conducting substances by electro-chemical deposition.

17,982. A. J. BOULT. London. Improvements in brushes for electric current generating and receiving machines. (L. Boudreaux, France.)

October 10, 1892.

18,025. A. B. SEE and W. L. TYLER. Manchester. Improvements in and relating to electric elevators. (Date applied for under Patents Act, 1883, sec. 103, March 14, 1892, being date of application in United States.)

18,037. W. C. MOUNTAIN. Newcastle-on-Tyne. Improvements in electric welding apparatus.

18,039. J. HARGREAVES and T. BIRD. Liverpool. Improvements in electrolytic cells and diaphragms.

18,066. F. W. GOLBY. London. Improvements in electric meters. (J. A. Dejardin, France.)

18,077. H. T. PAISTE. London. Improvements in electric switches.

October 11, 1892.

18,116. W. MATHIESON. Manchester. Improvements in, and relating to, electric arc lamps.

18,124. H. DAVIS. London. Improved electrical arrangement or device for the control of workmen's time checks.

18,142. W. A. BRAY. Leicester. Improvements in, and relating to, conduits for electric railways.

18,154. R. DRYSDALE. Birmingham. Improvements in electric arc lamps.

18,160. J. P. ANNETT. London. Improvements in telephonic receivers.

18,165. H. H. LAKE. London. Improvements in telephonic apparatus. (E. Noriega, Mexico.)

18,166. H. H. LAKE. London. Improvements in microphones. (E. Noriega, Mexico.)

18,170. E. A. DAVIS. Bristol. New or improved contacts for electrically giving signals while a door or gate is being opened.

18,179. O. SCHLICHT. London. A checking apparatus for telephones.

18,205. H. GARDNER. London. Improvements connected with machinery for making articles such as telegraph insulators from plastic material. (E. Francke, Germany.)

October 12, 1892.

18,242. T. P. RENNOLDSON. Ireland. Improvements in dynamo-electric generators and motors.

18,262. W. H. SCOTT. Norwich. Culverts for electric mains, made with pipes or tubes with insulators at intervals, arranged so that the conductors can be drawn in after the culverts are laid.

18,287. H. GARDNER. London. Improved construction of grid plates for holding the active material in secondary batteries. (E. Francke, Germany.)

18,295. A. L. FYFE. London. Improvements in methods of and means for the production electrically of spectacular effects.

October 13, 1892.

18,357. S. T. WYAND and L. SCHRAMM. London. Improvements in the construction of electrical switches.

18,359. A. L. DAVIS. London. Improvements in electric regulators.

18,363. J. P. THOMAS. London. Improvements in or relating to dynamo-electric machines.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

18,733. MARR and COLLIER. Electric telephonic apparatus.

19,546. HARTNELL. Alternating current dynamos.

20,214. WHITE. Electropathic appliances.

20,230. RIDER. Electric arc lamps.

1892.

4,185. STIENS. Galvanic battery.

14,035. PINTER. Electric incandescent lamps.

14,056. LAKE (Stanley and another). Electric motors.

14,769. THOMPSON (Cherry and others). Brushes for dynamos.

14,928. MEDHURST. Non-sparking switch.

COMPANIES' MEETINGS & REPORTS.

Eastern Extension, Australasia and China Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended June 30 last, to be submitted to the thirty-eighth ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on Wednesday next, at 2 p.m.:—

The gross receipts, including Government subsidies, for the half-year ended June 30, 1892, have amounted to £246,988. 16s. 6d., against £264,878. 6s. 11d. for the corresponding half-year of 1891.

The working expenses, including £26,359. 9s. 5d. for cost of repairs to cables and expenses of ships, absorb £79,281. 11s. 10d., against £71,476 15s. 8d. for the corresponding period of 1891, leaving a balance of £167,707 4s. 8d. From this is deducted £3,041. 2s. 11d. for income tax, £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, leaving £132,771. 1s. 9d as the net profit for the half-year.

Two quarterly interim dividends of 1½ per cent. each, amounting to £62,500, have been paid for the half-year, leaving £70,271. 1s. 9d. to be carried forward.

The contract, referred to in the last report, for the manufacture and laying on account of the Netherlands-Indian Government of a submarine cable between Acheen and the Company's system at Sumatra, has been carried out to the satisfaction of the Government, and the line opened for traffic.

During the half-year under review a further length of 443 knots of the Rangoon-Penang Cable was picked up, mostly in good condition, and taken into stock, making, with the cable previously recovered, a total of 825 knots out of 855 knots originally laid. The value of the recovered cable is estimated at £42,324, and after crediting capital expenditure with £20,000, the amount originally taken from capital towards the cost of the cable, the balance of £22,324 has been placed to the credit of the general reserve fund.

With a view to strengthening the system, a triplicate cable has been laid out of stock between Penang and Singapore. The Foochow-Shanghai section has also been partially renewed, and the route slightly altered at the mouth of the Yangtze-Kiang river, where interruptions from ships' anchors were becoming frequent. The cost of these operations, amounting to £25,974 and £5,307 respectively, has been debited to the general reserve fund.

An arrangement has been entered into with the Government of New Zealand for reducing the tariffs over the New Zealand cables from 8s. 6d. to 2s. per ten words for Intercolonial telegrams and from 1s. to 3d. per word for International telegrams, the Government guaranteeing the Company against three-fourths risk of any loss that may arise from the reductions, and the Company bearing the remaining one-fourth. It has also been arranged for the Government of New Zealand to join in the Australian guarantee and receive the benefit of the reduced rates with Australia, but owing to the losses during the first year of the experimental tariff having been greater than was anticipated by the colonies, the guaranteeing Governments have requested the Company to increase the charges for ordinary telegrams by 9d. per word, making the rates between Europe and Australasia as follows:—4s. 9d. per word for South and West Australia, 4s. 10d. per word for Victoria, 4s. 11d. per word for New South Wales, 5s. 2d. per word for New Zealand, 5s. 5d. per word for Tasmania, 9s. 5d. per word for Queensland. The changes of tariff will probably take effect from December 1st next.

Digitized by Google

Monte Video Telephone Company (Limited).

The following is the report of the Directors of this Company to be presented at the annual general meeting, to be held at the Company's offices, 96, Gresham House, Old Broad street, E.C., on Monday, the 31st inst., at 2 o'clock :—

The accounts for the year ended July 31st last show a profit of £6,468 18s. 4d., which, including the amount of £470. 6s. 11d. brought forward from last year, leaves an available balance of £6,879. 5s. 3d., after providing for all working expenses in Monte Video and London, and after writing off £129. 12s. 2d. for proportion of preliminary expenses, and £50 for depreciation of furniture at head office and in Monte Video. As stated in the last report, a considerable reduction has been effected in the general working expenses. In Monte Video the net decrease as compared with last year is £2,000, and in London £406. This latter item is almost entirely due to the reduction and final extinction of the Managing Director's salary, Mr. E. F. Powers having resigned this position.

The lease of the central office in Monte Video expired on January 1st last, and as the landlord positively refused to listen to any new proposal on any terms whatsoever, there was no alternative but to enter into an agreement to purchase the property, the immense cost and probable loss of subscribers that would have been entailed by taking other premises quite precluding the idea of removal. After much trouble, the terms of purchase were satisfactorily concluded by a contract dated February 2, 1892, entered into with Don Francisco Alzola, the landlord of the premises, and Don Miguel Harispuru (the Company's Attorney in Monte Video), and the manager, the purchase price being $45,000, payable by monthly instalments, terminating on February 2, 1893, when the central station will become the freehold property of the Company. The total amount paid off up to the close of our financial year, viz., July 31st last, was $20,000. Our capital account has thus been increased on this account by £9,575, as shown in the balance-sheet under the head of premises account. A slight addition is also made to the same account for cost of repairs to the premises, especially the lower portion of the building, which is now in thoroughly good order, and as soon as a suitable tenant is found, will be let off at a yearly rental of £250. Considering the gloom that has been overhanging the City of Monte Video throughout the period now being dealt with, the Directors point with satisfaction to the fact that the net result of the year's working is £1,622 more than last year. As, however, the instalments on account of the premises have been paid out of the earnings of the Company, the Directors consider the right course to adopt is to recommend that the sum of £5,000, as advised by the auditors, be carried to reserve account, and the balance of £1,879. 5s. 3d. be carried forward to next year.

The Directors regret to have to report some falling off in the number of subscribers, due almost entirely to the continued great depression in business in Uruguay, which depression, in place of having decreased, as was looked for at the time of our last report, has during the past twelve months become more accentuated. As soon, however, as any general improvement takes place in Monte Video, it is confidently expected that the present number of 1,330 paying subscribers will be materially increased.

There has been some change in the composition of your Board of Directors since our last meeting. In February last Mr. Arthur Holland sent in his resignation as Chairman of the Company, and Mr. Herbert Ward was elected in his stead. Mr. T. D. Peters also found it necessary to resign his seat on the Board, being called away on business in the River Plate. Mr. C. H. Sanford has been elected a Director of your Company, and Mr. E. F. Powers, as already stated, is no longer Managing Director, but continues on the Board. During the past year your Chairman, Mr. Herbert Ward, visited Monte Video in order to inspect the management and plant, and his report informs us that he found the management perfectly efficient, and that good order prevailed throughout the Company's central and district offices.

In accordance with the Articles of Association Mr. C. H. Sanford retires *per rotâ* from the Board, and being eligible, offers himself for re-electon. The auditors, Messrs. Gérard van de Linde and Son, also retire, but offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

JOHN SAUNDERS (LIMITED).—This Company has been registered with a capital of £8,000, in £5 shares, to carry on the business of wholesale and retail ironmonger, gas, electric light, sanitary and general engineer, electric light fittings manufacturer, &c., carried on by J. F. H. Saunders, at High-street, Kidderminster.

THEWLIS AND GRIFFITH (LIMITED).—This Company has been registered with a capital of £20,000 in £10 shares, to carry on the business of tool and file manufacturers, mechanical and electrical engineers, metal workers, steel makers, &c.

UNITED ELECTRIC TRAMWAYS (LIMITED).—This Company was registered on October 22, with a capital of £30,000 in £5 shares. The objects are to acquire by purchase, lease or otherwise, tramway undertakings in the United Kingdom and elsewhere, and to develop and work the same by electricity, horse, steam or other power ; to acquire and undertake concessions, contracts, &c., for establishment, working and maintenance of tramways and to carry on the business of tramway proprietors, electrical engineers and contractors, suppliers of electricity, &c. The subscribers are :—

	Shares.
A. M. Orchard, 4, Capel-terrace, Forest Gate, E.	1
A. Wheat, Waverley High-road, Upper Clapton	1
L. du Cane, 50, Old Broad-street, E.C.	1
A. Chabot, Fernleigh, Romford	1
A. J. Kent, 8, Cross-road, South Wimbledon	1
A Robinson, 20, Erpingham-road, Putney	1

The first Directors to be appointed by the above-named. Qualification to be £50 stock or share. Remuneration, £150 each per annum (£50 per annum extra for the Chairman), and 10 per cent. of the net profits after the payment of an 8 per cent. dividend. Registered office : 37, Queen Victoria-street, London, E.C.

MISCELLANEOUS.—BAILEY'S INVENTIONS SYNDICATE (LIMITED), general engineers ; capital £2,000, in £5 shares.——BOHM AND CO. (LIMITED), glass makers, insulator manufacturers, &c. ; capital, £20,000, in £1 shares. ——FORREST AND SON (LIMITED), electric launch builders, &c. ; capital, £50,000, in £5 shares.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to August 5th, has been filed. The Company was registered on December 11, 1885, with a capital of £300,000, in £10 shares. 23,600 of the shares have been taken up, the full amount called, and all calls paid.

ELECTRIC ARMS AND AMMUNITION SYNDICATE (LIMITED).—The annual return of this Company, made up to September 12th, has been filed. The Company was registered in October, 1889, with a capital of £40,000, in £100 shares. At the time of making up, 290 shares were taken up, of which 210 were issued as fully paid. Upon the remaining 80 shares £70 per share had been called, resulting in the payment of £5,540, and leaving £60 as yet unpaid.

ELECTRIC DATE AND TIME STAMP COMPANY (LIMITED).—At an extraordinary general meeting of this Company on September 6th a special resolution was duly passed, and at a meeting held on October 4th was duly confirmed, that the Company be wound up voluntarily, and that Mr. J. M. Henderson, of 2, Moorgate-street-buildings, be appointed liquidator. The Company was registered in April, 1888, with a capital of £100,000, in £1 shares, to acquire and work Patent No. 15,717 of 1887, and generally to buy, sell, hire, let, and deal in all kinds of articles and materials capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. The capital was afterwards raised to £121,000 by the creation of 21,000 deferred shares of £1 each. The last return was filed November, 1891.

ELECTRIC LAMP COMPANY (LIMITED).—An agreement recently filed between T. P. C. Crampton, electrician, and Albert Essinger and this Company states that the said Thomas P. C. Crampton is the inventor of certain improvements in electric arc lamps, and also of an improved form of carbon for use in electric arc lamps, and that the Company agrees to buy the same in consideration for 3,000 fully-paid shares. The patents are No. 10,640 (1889), for Great Britain, price £500 ; France, No. 206,804 (1890), £400 ; Austria, No. 51,074/9,903 (1891), £300 ; Italy, No. 278, 425/23, Vol. LIV./XXIV. (1890), £300 ; Spain, No. 11,027 (1890), £300 ; Belgium, No. 91,138 (1890), £300 ; Germany (not yet granted), £400 ; U.S.A., No. 442,018 (1890), £500. Registered office : 26, Thavies-inn, E.C.

ELECTRICAL INSTALLATION COMPANY (LIMITED).—The statutory return of this Company, made up to August 25th, has been filed. The Company was registered in May, 1892, with a capital of £1,800, in £1 shares. At the time of making up all the shares had been taken up, 3s. 4d. per share called, and all calls (£300) paid.

ELECTRICAL SUPPLIES AND FITTINGS COMPANY (LIMITED).—The annual return of this Company, made up to August 8, 1892, has been filed. The Company was registered in October, 1890, with a capital of £20,000, in 3,800 ordinary and 200 founders' shares of £5 each. At the time of making up 246 ordinary and 98 founders' shares had been taken up. The full amount had been called on 240 ordinary and 78 founders' shares, resulting in the payment of £1,470, leaving £120 in arrears. No calls have yet been made on the remaining shares.

ELECTRO-CHEMICAL SYNDICATE (LIMITED).—In answer to inquiries from the Registrar of Joint-Stock Companies, Mr. Lovell, solicitor to the above Company, writes that no business whatever has been transacted by the Company, which was registered in October, 1890, with a capital of £5,000 in £1 shares, to acquire certain patents, particulars of which were not given.

CITY NOTES, &c.

CALLS DUE.—*October 31 :* ISLINGTON AND GENERAL ELECTRIC SUPPLY, £1 on 45,000 £5 shares ; NEW TELEPHONE COMPANY, £2 on 48,000 £10 shares. *November 15 :* CITY OF LONDON ELECTRIC LIGHTING COMPANY, £2 on 20,000 £10 Cumulative Six per Cent. Preference.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended October 23 were £865, as against £756 for the corresponding period of last year, being an increase of £109. The

Digitized by Google

total receipts for half-year amount to £13,383, against £12,171 in the corresponding period of 1891, being an increase of £1,212.

DIVIDENDS PAYABLE.—*November 1:* CALLENDER'S BITUMEN TELEGRAPH AND WATERPROOF COMPANY, 8 per cent. interim dividend for the half-year.

INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the half-year ended June 30th at the rate of 5 per cent. per annum. This dividend is payable on and after the 1st prox.
